Cover picture

A fissure eruption in November 1978 on the Asal graben, southernmost spreading segment in Afar. A 40 m high spatter rampart was erected on the fissure and 16 m^3 of basalt was extruded. In the background are the normal faults of the eastern scarp of the graben. For an examination of these seismic and volcanic events see p.17. New isotopic data are presented on p.56.

...the new honestly priced Liquid Scintillation and Automatic Gamma Counters from Philips...

...the end to price confusion.

Just how important is price?

Of course price is important. But not price at any price.

Price not as a result of your ability to beat the salesman down. With Philips you won't have to argue about price.

The Philips price is realistic. Our price is based on the value of our products.

No more – no less.

The new Philips Liquid Scintillation and Automatic Gamma Counters.

The new generation for the eighties.

In styling and performance.

In our price the availability of service is included. For at least 10 years.

In our price the availability of spare parts is guaranteed. For at least 10 years.

Compare Philips with others in this field. For price and performance.

We invite your comparison. To find out the facts fill in the coupon, or write, telephone or telex, but whatever you do, contact us.

Please send me detailed information on:

- ○ Philips Liquid Scintillation Counter.
- ○ Philips Automatic Gamma Counter.

MIX AND SPIN PERCOLL™

DENSIT MARKER BEADS
NOW AVAILABLE
for calibration of gradients of Percoll

Now centrifugation is simpler, quicker and gives much greater resolution than you ever thought was possible.

- Self-generating gradients in 30 minutes or less
- Isoosmotic throughout the gradient
- Non-toxic to cells and viruses
- Does not interfere with enzyme assays or quench radioactivity
- Low viscosity for rapid isopycnic or rate zonal separations
- Suitable for cells, viruses and subcellular particles

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

Abnormal characteristics in crystallisation of $Ca(PO_3)_2$ glass	*Y. Abe*	55

An energy briefing that's updated 22 times a year...

Give us 30 minutes every other week and we'll give you...

Technology reports

Our energy specialists alert you to the latest developments in clear, concise, cumulative reports that stress information you can use. *Energy Research* explains -- without the jargon -- such technologies as coal liquefaction, fusion, photovoltaics, cogeneration, fluidized-bed combustion, biomass. . . who is doing the work, where the technology stands, what are the problems, when it will be available, and how much it will cost. *Energy Research* gives you more insights in less time than any other journal.

Economic outlooks

This year $8 billion will be spent on energy research worldwide. The U.S. Government alone will spend $3 billion. To plan intelligently, you need to know where the money is going, and why. *Energy Research* gives you a fortnightly briefing on what to expect next month, next year and next decade.

Worldwide coverage

Timely reporting from our correspondents in Western Europe, Eastern Europe and the Far East -- as well as those across the U.S. -- alert *Energy Research* subscribers to research opportunities months, sometimes years, before they are widely recognized.

Literature scan

Hundreds of periodicals carry energy information. *Energy Research* scans all the literature and brings the best books and articles to your attention. Analyses by outside experts help you decide which books to buy. An annual index and frequent references to past issues give you a handy way to follow the progress in each technology.

ENERGY
RESEARCH REPORTS

is not the last word — it's the first!

E"E. ' T. 'E B. :IC OUTFIT ' OI. 'T: THE WAY TO MAXIMUM MICROSCOPIC PERFORMANCE.

There are many valid reasons why research workers the world over decide in favour of a LEITZ ORTHOPLAN. The most important one is the LEITZ plan-apochromats, which produce images of unsurpassed resolution and edge-to-edge pin-sharpness. They also permit the utilization of a field of view which with large-field eyepieces is up to 140% larger than what has hitherto been possible to observe in a conventional microscope. This means more and better information at a glance, without the need to adjust the object.

There is not a single optical microscopic method of illumination and contrasting for which the LEITZ ORTHOPLAN cannot be adapted very quickly, to be instantly ready for any microscopic problem.

But the possibilities of the LEITZ ORTHOPLAN far exceed the field of classical microscopy.

They make this microscope the central optical component of all quantitative methods of microscope photometry with the LEITZ MPV system, and in electronic image analysis with the LEITZ T.A.S. the LEITZ consultant will be delighted to call on you and to demonstrate in your own laboratory how the LEITZ ORTHOPLAN can solve your special microscopic problems. All you have to do is send us the coupon below.

☐ I should like to know more about the LEITZ ORTHOPLAN and would be grateful for your detailed prospectus.
☐ I should like to arrange a meeting with the LEITZ consultant soon.

INDEXES

Annual Indexes are available for the years 1971-1978. The year's papers are listed by both author and subject.

Prices: UK: £5.00
Rest of World US$10.00

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World: US$6.00,
three for US$16.00.

To order, please send details and correct remittance to:

Nature,
Circulation Department,
Macmillan Journals Limited,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

Time for a policy on scientists' jobs

SHIRLEY Williams, when she was Secretary of State for Education and Science, was apt to complain that there was no vocal lobby for science, although there was for everything else from aardvarks to zither players. Well, that is about to be rectified when next Tuesday representatives of the Association for Researchers in Medical Science (ARMS) lobby the House of Commons about increasing unemployment among scientists.

Anne Simmonds, the convenor of ARMS, in an interview this week (p7) explains that she herself never expected to be redundant when she set up the organisation; she is a widely respected biochemist whose case underlines the difficulties and inconsistencies of assuming that in a time of cuts the "truly able" (in the words of the Medical Research Council) will find appropriate scientific employment. Moreover, it is misleading for the MRC to claim, as one official told *Nature*, that short term contract workers "are not geniuses". While this is no doubt the case (for most), it draws attention from another unpalatable but undeniable fact that many of the tenured positions filled during the boom years of the late fifties and early sixties are occupied by people less able than many in the queue behind them.

But this is merely to pose the problem: a policy of the "truly able" is one which fudges the figures to match the facts; the number of "truly able" is by definition the number who get jobs; the argument is circular and it is no policy at all.

What is needed, and urgently, is some hard thinking about the nature of scientific careers and what government can do to make proper use of this absolutely central innovative resource. It is utter folly for a government bent on establishing economic recovery to waste its scientific resources — its scientists — through a *laissez faire* policy which both wrecks individual careers and discourages those rising on the ladder. The Science Research Council, which is responsible for most basic research in the UK, has some forward looking policies, particularly on the relation of science to industry, which must be encouraged; and the Medical Research Council which appears to be relatively backward in this regard would do well to follow suit. But some central government initiatives are required to coordinate these efforts within a broad demographic policy for science and engineering. Here is a case where science is too important to be left to the scientists, a case where the Prime Minister should exercise her stated aim of coordinating science policy where that is necessary (see *Nature* 27 September p249).

One particular matter to which she might pay attention is the role of research students, which is the engine of production of the "excess" of short-term contract workers. The pattern of using these students as a form of cheap labour for adding to a researcher's list of publications arose during the expansion of the universities, when it was virtually guaranteed that this apprenticeship would lead to a university position. This pattern continues, although the job at the end is no longer there. Breaking the pattern by greater selectivity in appointments to studentships (perhaps by examination) carries with it the further problem of what substitute technical assistance can be provided for existing researchers, and at what cost; and how to place those graduates who would at present go on to research. But this would bring the 'jobs problem' in a scientific career back to the age of 21, where it is considerably more tractable than at 24 after a PhD, or even 30 and beyond after a series of short-term contracts. We recommend to you, Prime Minister, that you ponder these matters, to the benefit not only of science, but also of the British economy. □

Soviet germ disaster shock?

SPECULATIONS on possible Soviet research into bacteriological and chemical weapons were revived this week by *Now!*, Britain's recently-founded answer to *Newsweek*. A two-page article, entitled "The Great Russian Germ War Disaster", gives a circumstantial account of an accident at a factory in Novosibirsk, last June, shortly after which, persons living in the vicinity "started to go down with a mysterious illness". "Thousands" of people, it is said, were affected, with the death rate among the victims "very high". The bodies of those who succumbed, it is reported, were delivered to the relatives in "sealed coffins". When a few relatives succeeded in examining the bodies, they were found to be covered in "brown patches".

The story, *Now!* makes clear, was nowhere reported in the Soviet press, but was transmitted to *Now!* by a "traveller". It should be recalled, however, that except for international air-crashes or accidents involving foreigners, it is very rare for the Soviet press to report accidents. Certainly, to judge from the *Now!* reports, something untoward happened in the Novosibirsk factory — but the account, as *Now!* itself admits, is consonant with a Séveso-type chemical disaster, which need not necessarily have any connection with the military at all. The allegation of bacteriological warfare seems to be based on the fact that a molecular biology institute was established at Novosibirsk some three years ago.

Certainly, the now famous Kyshtym nuclear devastation of 1958 is a constant reminder that the Soviet Union has the logistic capacity to mount a major cover-up operation, even to the extent of evacuating large tracts of country. Moreover, in conditions of a controlled press, even the most innocent natural disaster is liable to generate wild rumours. (Last winter's explosion, which wrecked the Rotunda building in Warsaw, was attributed, in popular belief, to a bomb planted by the authorities . . . so that the dissident "Committee for Social Self-Defence" issued an appeal to the government to allay panic by publishing the result of the commissions of enquiry).

The official Soviet News Agency TASS always vehemently denies any rumours of bacteriological weapons research. Nevertheless, if what happened at Novosibirsk had no military applications, it is perhaps unfortunate that, immediately following the *Now!* allegations, the Soviet press attache in London was away on sick leave, leaving no deputy empowered to comment. □

Nature Vol. 282 1 November 1979

Can Yankee ingenuity keep US physics on the ball?

As US high energy physicists bemoan a continued tightness of funds, West Coast scientists are proposing an ingenious way of keeping up with European colleagues — at a fraction of the cost. **David Dickson** reports

Inflation is threatening to upset the fragile truce agreed two years ago between the US research community and the Office of Management and Budget over the appropriate level of support for high energy physics.

The agreement negotiated by the Department of Energy guarantees a constant 'floor' of support (adjusted for inflation) for research at the three main accelerator laboratories — the Fermi National Laboratory, the Brookhaven National Laboratory, and the Stanford Linear Accelerator Center — pegged at the 1979 level of $300 million a year; but it promises no more, unless a particularly good case can be argued.

Initially physicists accepted the agreement since although it means less money than they would have liked, at least it provided medium-term security. But now a higher-than-anticipated inflation rate means that the physics budget is falling considerably behind steady-state funding, perhaps by $30 million over the next two years; and this is having serious implications for current and projected research programmes.

It also increases uncertainty over whether Congress can be persuaded to support two projects which would enable US physicists to keep up with their European counterparts as the latter pursue the intermediate vector boson (Z^0) predicted by the Nobel-prize-winning theories of Steven Weinberg, Abdus Salam and Sheldon Glashow.

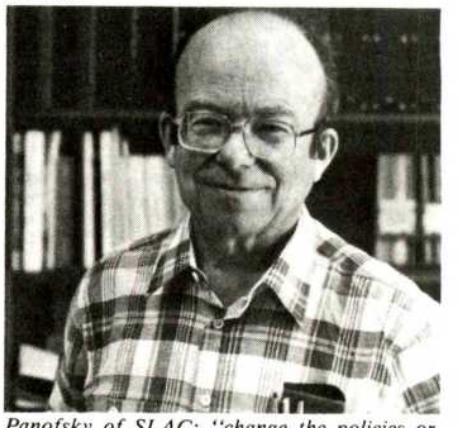
The first is a new facility proposed by Fermilab to help investigate the proton-antiproton collisions that should produce the Z^0; the second is an ingenious plan devised by Dr Burton Richter of SLAC to study the physics of the Z^0 and its decay particles at a fraction of the cost of Europe's proposed 100 GeV electron-positron collider, LEP.

Compared to the early 1970s, the current picture for US high energy physics is far from gloomy. Indeed from one point of view the community is doing very well, with major construction projects under way at the three main laboratories, as well as Cornell University. "The current programme is basically sound, and there has certainly been a reversal in prospects since 1975" says Dr Tony Samios of Brookhaven.

There are, admittedly, some slight hitches. At Brookhaven, Long Island, for example, designers working on ISABELLE, the 400 GeV intersecting proton storage rings, are having difficulty in getting the superconducting magnets to produce the required magnetic field; it's a problem which has led to "particular agony over the past few months", says project director Dr Jim Sanford, though he remains confident that it can be solved by the time the magnets should be ready for mass production next spring.

Elsewhere the picture is brighter. Fermilab near Chicago claims to be up to schedule with its own production of superconducting magnets, designed to double the accelerator's energy from 500 to 1000 GeV; SLAC, in California, injected its first positron beam into its positron-electron collider PEP last week-end, and is planning to start operating on schedule — and within the $78 million budget — in late January 1980.

The biggest cloud around is rising inflation. The DoE's budget allocation for the current fiscal year allows for 7% inflation. In real terms, inflation in the US is well into double figures; and construction costs on new facilities have increased even more. The projected 1981 budget of around $350 million could be about $20 million less in real terms than the 1979 level previously promised.



Of particular concern are the high electricity costs caused by oil price increases, a factor to which accelerators, with their vast power consumption, are particularly vulnerable. Brookhaven, for example, has recently been faced with an almost 50% increase in its power rates; and at SLAC, the extra power needed by PEP will require shifting to a new source of supply at much less preferential rates, which will increase the laboratory's annual power bill from $2 million to almost $5 million when PEP is fully operational.

Since salaries are fixed, the extra costs will have to be absorbed by operating budgets. The result could be a significant curtailment of experiments. SLAC is already warning that when PEP comes on line, it will have to operate considerably below capacity; and Dr Leon Ledermann, Fermilab director, is talking of having to close down a complete experimental facility, the 15-foot bubble chamber used for neutrino-beam experiments, if additional support is not forthcoming.

Up to now, physicists have told the DoE they were confident a viable national programme could be maintained at the three accelerators on the $300 million figure. "Now either the policies have to be changed or the funding has to be changed; we cannot pay lip service to both", says Dr Wolfgang Panofsky, director of SLAC.

Ledermann of Fermilab: experiments may have to close

Panofsky of SLAC: "change the policies or change the funding"

What makes the situation particularly frustrating is that US physicists see themselves having to sit back while their European colleagues using new facilities such as the super proton-synchroton (SPS) at the European Centre for Nuclear Research (CERN) and the proposed LEP, explore the new areas of physics that will be opened up if the existence of the Z^0 particle is confirmed.

The two proposals now on the drawing board for keeping up with these developments would therefore fill a major gap that could develop within the US high energy physics programme. Fermilab's plan is to build a new machine which will help physicists to study the proton-antiproton collisions expected to produce the Z^0.

The plan requires a pre-booster storage ring, which would collect anti-protons created by protons extracted from Fermilab's main ring, and cool them sufficiently to reinject them in the opposite direction to the protons. The machine would come on line after PEP, which is expected to be the first to discover the Z^0 (if

0028-0836/79/440002-02501.00

©1979 Macmillan Journals Ltd

it exists) soon after coming into operation in 1981 (perhaps). It would produce a considerably higher collision rate than the equivalent European machine; and Fermilab physicists are hoping that this will help persuade Congress to provide the necessary $26 to $29 million.

The second proposal, devised by Dr Richter, is to create single collisions between individual pulses of electrons and positrons. Both would be produced on the SLAC linear accelerator, using techniques now being developed to increase the beam energy from around 25 GeV to 50 GeV; they would then be made to circulate in opposite directions around a circular tunnel, and carefully aimed to collide with each other.

Since each pulse will only produce a single collision, the event rate will be much lower than for the constantly circulating pulses in storage rings at a comparable energy. Dr Richter proposes to make up for this, however, by tuning the two beams to collide at a centre of mass energy calculated to be equal to be the mass of the Z^0 particle, using the resonance at this energy to increase the luminosity.

If the Z^0 does exist, then the Single Pass Collider, as the project is known, would become a virtual factory of decay particles with an event-rate around 10^6 a year, and the facility could be used by many different users. If the Z^0 does not exist, the event rate will be very much slower; "but the physics will be much more interesting, since it would mean a basic flaw in the theory", says Dr Richter.

The design would lack the power and versatility of LEP, scheduled to reach 100 GeV per beam, and to be built by the late 1980s. But at a cost of $60 million — compared to LEP's $1000 million — plus the fact that it could be in operation as early as 1984, the proposal is attractive to US physicists. "It is an extremely clever idea, real 'Yankee ingenuity' " says one.

It all comes down to money. Dr Richter has asked the DoE for $800,000 to carry out a preliminary design study; and says that, if given the go-ahead by the department and Congress in the 1982 fiscal year budget to be prepared next summer, the collider could be completed in under three years.

Whether Congress will go along with either this or the Fermilab project remains the great unknown; and few are over-optimistic. Last week the DoE's High Energy Physics Advisory Panel (HEPAP) supported a proposal that its chairman, Dr Sidney Drell of SLAC, write a letter to the department expressing grave concern at the current funding position; and warning that if there was not an immediate infusion of extra funds — at least sufficient to restore the budget to the promised "floor" — the panel would consider withdrawing its endorsement of the national programme. Department officials at the meeting promised the physicists a sympathetic hearing; but no more than that. □

NIH director unlikely to grant exemption from controls for DNA experiments

The director of the US National Institutes of Health, Dr Donald Fredrickson, seems unlikely to accept in full the recommendation of the Recombinant DNA Advisory Committee (RAC) that a large body of recombinant DNA experiments be exempted from the guidelines established by the NIH, following widespread criticism of the implications of such a move.

Sources within the NIH say that Dr Fredrickson will probably approve a significant reduction in the safety precautions needed to carry out most experiments using as host the disabled K-12 strain of the bacterium *Escherichia coli*; these are said to account for between 80 and 85% of all experiments using recombinant DNA techniques.

But whereas the RAC, in a split 10 to 4 vote, decided at its last meeting in September to recommend *exemption* for the guidelines for such experiments — with merely the ruling that they should be registered with local biohazard committees, and should preferably be carried out at the minimal P1 physical containment level — Dr Fredrickson is likely to insist that the P1 conditions be enforced. This will include strict adherence to technician training requirements, and a ban on practices such as mouth-pipetting.

The NIH has had a flood of comments since the proposal to exempt the experiments was first put forward by RAC members Dr Allen Campbell and Dr Wallace Rowe at the committee's meeting in May. Many scientists wrote supporting the proposal, including in particular a petition signed by 183 scientists attending the Gordon conferences on nucleic acids and on biological regulatory mechanisms.

Others, however, have expressed concern about the implications of such a drastic move. Professor Roy Curtiss, of the department of microbiology at the University of Alabama in Birmingham, wrote to Dr Fredrickson criticising the proposed exemptions as premature, given the uncertainties that still exist over the hazards of recombinant organisms. "I believe that the RAC's recommendation to you was based more on the politics of science than on its data", he wrote.

Fredrickson: reviewing the arguments

In addition, the Natural Resources Defense Council in New York has demanded that an environmental impact statement be carried out for the proposed safeguard reductions, arguing that "the proposed exemptions are of such breadth and importance as to require full compliance with the National Environmental Policy Act."

In view of the controversy surrounding the committee's recommendation and its implications, Dr Frederickson has been carrying out a detailed review both of the arguments used during the RAC meeting, and of the data used to support them.

The results of this review will not be known for several weeks. However it is thought that Dr Fredrickson is reluctant to face the criticism that total exemption would involve.

For example, two weeks ago the citizens of Amherst, which has introduced a local ordinance requiring recombinant DNA research at the University of Amherst to be conducted under the NIH guidelines, agreed to require adherence to the 1978 revision of the guidelines, rather than their stricter 1976 original version.

However according to Dr Bruce Levin, a research scientist at the university who has been closely involved in the local debates, there would probably be strong resistance from the local community if a large proportion of the experiments were to be exempt from regulation.

Dr Fredrickson, however, is said to be prepared to accept most of the arguments in favour of a substantial reduction in required containment levels for many experiments involving the K-12 strain; one of the few areas still to be resolved is whether local committees would be required to give prior approval to experiments using biologically active materials, such as active polypeptides or active proteins.

The NIH is paying particular attention in its review to uncertainties that have arisen as a result of various risk assessment experiments, such as those which indicate that bacteria into which plasmids have been introduced can survive considerably longer than expected in the human gut.

Meanwhile staff members for Senator Adlai Stevenson's science and technology subcommittee are preparing legislation that would require all non-federally supported research involving recombinant DNA techniques — in particular that carried out by private companies — to register their experiments with the NIH. At present companies can register; but the arrangement is voluntary. □

Pollution control: how an EEC directive muddied the waters

Britain and the EEC have been arguing for many years about the best way of controlling pollution. The conflict arose not because anyone disagreed that certain substances should be controlled but because the EEC wanted to lay down a blanket standard of emission into rivers from sewers and factories.

Britain argued that this was wasteful and inefficient because it took no account of the use of a particular river nor its capacity to dilute and disperse waste materials. Britain wanted local controls, based on local conditions and local usage, as long as there was no risk to human health or animal life.

Eventually, in December 1975, the EEC Council of Ministers compromised and agreed to let the British control pollution in their own way. But now new directives have been issued from Brussels concerning the control of specific substances in water and they put a question mark over that 1975 agreement

Extracts from a speech by Lord Ashby (right) to the House of Lords in London last week

The first of the 'drin' Directives sets a limit for the emission of dieldrin. It is 60 parts per billion in the waste water discharged into the river. Clearly, the Commission considers that this is going to be a little dificult because it allows factories time to build treatment plant. The limit is not to become binding until 1986, six years ahead. The second Directive offers the other option, the one we asked for: an environmental quality objective for the river into which the wastes are discharged. The level proposed for this is 0.005 parts per billion. Unlike the first option, this level has to be reached in two years' time, which gives the impression that it is an easier option.

These requirements make a nonsense of the options agreed by the Council of Ministers after great pressure from the British Government in 1975. First, the two options are mutually contradictory and inconsistent. Suppose we complied with the first Directive. Suppose we reduced emissions to 60 parts per billion in the Calder River (the river most affected in the UK). Would this result in an environmental quality objective of 0.005 parts per billion? It certainly would not. After doing a little arithmetic, which is fully within the capacity of the staff of the Commission, it has been found that it would need a flow of one hundred times that of the Calder at its minimum value in order to produce that degree of dilution; in fact many times the flow of the Thames at Teddington.

So the two proposed standards simply do not match. This could either be a deliberate soft option for those member states that want to choose an emission standard or it is a sign that the scientific basis for these figures is very suspect. That is not the only difficulty. The standard of 0.005 parts per billion is inconsistent with two other Directives which have already been published by the Commission and agreed by the Council on their own definition of pollution. For instance, the Commission has already agreed in principle that the level of dieldrin in water to be used for human consumption is to be not more than 0.1 part per billion — that is, 20 times higher than the level proposed in this Directive — so the limit has obviously not been set to make the water safe to drink.

What about the fish? Three years ago the Commission published its own water standards for fish. In this Directive, which has now been adopted, pesticides are not included at all. However, it is possible to calculate what the safe level will be because it is known that for a coarse fish like the roach — and we are talking about coarse river fishery in the Calder — about two parts per billion is the beginning threshold value for damage, and the level of dieldrin in the Calder varies a good deal; but it is in the region of 0.1 part per billion, that is one-twentieth of the danger level.

So on two counts, both falling in the definition of pollution by the Commission itself — human health and the health of fish — the environment quality objective proposed just does not make sense. There remains a very important fact, that the fish and other living things accumulate dieldrin from water, and they concentrate it enormously in their own tissues. If people then eat the fish they might be at danger. Experts are reluctant to commit themselves to precise figures for the amount of dieldrin which fish and other living things will accumulate from the environment. However, it is a general consensus that it is a multiple of 10,000 of the concentrations outside.

If the Calder carried trout, salmon or eels — which it does not because of pollutants other than dieldrin — then there would be an indubitable case for monitoring the dieldrin level of the fish. Then consent levels on the river could be imposed which would guarantee that the acceptable daily intake, if people ate the fish every day would be safe. This is exactly what is being done all the time in Britain in waters where fish are eaten. But coarse fish are not eaten in Britain, and the present use to which that stretch of water is put does not justify such drastic lowering of the dieldrin level either — to come back to the Commission's own definition — on grounds of hazards to human health or on grounds of harm to living resources.

Finally, there is a practical difficulty about settling a standard of 0.005 parts per billion which the drafters of the Directive do not seem to have noted. The waters which fall into a river from a mothproofing plant such as those on the river Calder (these plants produce the dieldrin) contain many impurities. If one wants to analyse the water containing those impurities for the concentrations of dieldrin, one simply cannot detect levels lower than about 0.01 parts per billion, so the level proposed in the Directive is one which could not in fact be measured, except by most refined and difficult research techniques. So the idea of monitoring concentrations of that level as a routine matter simply is not on.

These are the reason why I think it is not an exaggeration to say that "nonsense" is the word that has to be used for this option offered to the nation states in the Community which prefer to take environmental quality objectives rather than emission standards. How did the Commission come across this figure? The Directive states that the figure was reached "after consulting a group of national experts", and also on the basis of a study made by consultants in the Agricultural University of Wageningen in Holland. But as with previous Directives about the environment, scientific evidence for the decision is not given and the consultants' report is not published.

However, I have talked with the British experts in this matter and their view is clear from what I have already explained to your Lordships. I have managed to see a copy of the consultants' report. Again for the record, I should like to read the conclusion of that report: "This leads to the rather disappointing conclusion that most toxicological studies made so far with the aim to assess the environmental hazards of aldrin, dieldrin and endrin . . . have been inadequate in the sense that for the aquatic environment no practical environmental threshold levels can be derived from thier results".

The Commission then concludes, based on that conclusion, without providing any of the consultants' data, that the

0028-0836/79/440004-02$01.00

©1979 Macmillan Journals Ltd

environmental quality should be set at a level which is inconsistent with two other Commission Directives, unjustified on grounds of safety to human beings or wildlife, and below the limits detectable by routine analyses. As one of our witnesses put it, data appeared to have been plucked out of the air using a concentration factor much higher than the one thought to be reasonable by British experts.

We all want to reach amicable agreement with the Commission over an environmental policy for the Community, and we all agree that dieldrin is a harmful substance which ought be phased out as soon as satisfactory alternatives are found. But we see no prospect of amicable agreement unless the Commission can be persuaded to adopt two simple principles when it prepares its Directives.

●The first principle is to abide by a declaration of the Council of Ministers made in 1973 about the environment. This declaration is the only authority for having a European environmental policy at all. It states that protection of the environment should be achieved "at the lowest cost to the Community" and that in setting quality objectives "proper account must be taken of the specific characteristics of the regions in question".

This means the deployment of our limited resources in places where they could be most cost-effective. It means that we should have different environmental qualities for rivers, depending on whether they carry game fish, coarse fish or no fish at all. Following this policy in Britain over the last 20 years, we have increased the amount of unpolluted rivers by about 4,500 kilometres and we have diminished the amount of badly polluted rivers by about 1,500 kilometres. I doubt whether any other member state in the Community can match that record. A doctrinaire pursuit of uniform emission standards would wreck this policy.

●The second principle is to insist on free and candid disclosure of the scientific evidence on which Directives are based. It simply is not good enough for the Commission to say, "After consulting a group of experts, we set such and such standards". The Select Committee has now got plenty of evidence that the experts' advice is not always taken. To comply with some of these Directives — for instance, that proposed for fish — would put member states to enormous expense and to expect them to incur this enormous expense without even seeing the data on which the standards are based is, I suggest, an intolerable situation. I am afraid it is true — and we regret it — that there will be perpetual wrangling over environmental policy in the Community until this freedom of information is secured.

Compared with the Common Agricultural Policy, the Commission's environmental policy for Europe may well be a small matter. But it is a perpetual source of irritation. ❜

UK to tighten asbestos controls

TIGHTER safety standards for asbestos are proposed in a report published last week by the UK Health and Safety Commission (HSC). The report, prepared by the commission's Advisory Commission of Asbestos (ACA) makes proposals, which according to the committee's chairman Mr Bill Simpson would, if they became law, "mean that Britain would share with Sweden the most stringent asbestos rules of any country".

The report recommends that the standards currently in operation regulating asbestos fibre concentration should be halved to 1 fb ml^{-1} for chrysotile (white asbestos); reduced four-fold to 0.5 fb ml^{-1} for amosite (brown); and that a statutory ban be placed on crocidolite (blue) in the UK. In addition, until such fibres as crocidolite are replaced, the standard for its removal should remain at the present 0.2 fb ml^{-1}.

It is proposed that the new standards should take effect from 1 December 1980 and that in future they should be referred to as "control limits" rather than "hygiene standards", the latter definition suggesting an asbestos concentration below which exposure is safe.

Simpson firmly believes that the new standards will reduce the incidents of asbestos-related diseases in future. It is the report's view that exposure to one fibre per mille of chrysotile daily over a period of 50 years will cause an increased mortality rate of 0.02 to 1.25 per cent. This prediction is based on the results of the only three surveys — two North American, one British — which provided adequate dose/response data. Calculations of mortality rates based on these results have their problems, however, as the report readily admits. Much of the data in these surveys on asbestos concentration was obtained by measuring particle counts, a far less precise method than the normal practice of counting fibres.

As far as the public is concerned, the report concludes that there is no quantitative evidence of risk from over-exposure to asbestos dust. The report says that despite the fact that there is a high proportion of individuals, especially in urban areas, with asbestos fibres in their lungs, there has been no general reporting of asbestosis. Accordingly the report suggests that "there may be a threshold level" below which asbestosis is not detectable.

This, however, does not hold true for the carcinogenic properties of asbestos. The report states baldly that there is "no evidence" for the existence of a threshold below which lung cancer or mesothelioma — of the pleura or the peritoneum — will not occur. It is the report's view, however, that crocidolite is consistantly more dangerous than chrysotile and should be treated accordingly. Swedish and Dutch regulatory authorities agree.

The report acknowledges that all forms of asbestos will cause lung cancer. In numerical terms, lung cancer is the great killer but the report says "included in this excess mortality from lung cancer is a substantial element due to the syenergistic action of tobacco with asbestos, which cannot therefore properly be attibuted to the effect of asbestos alone". The asbestos industry has always made much of this synergism to play down the role of asbestos in the aetiology of lung cancer.

On the quesion of death due to mesothelioma, the report is unequivocal; the majority of these are due to exposure by chrysotile. Death from mesothelioma reported in American asbestos workers (the report says) are attibutable to exposure to both amosite and chrysotile and not to chrysotile alone.

Deaths from mesothelioma in the UK doubled between 1967 and 1976 — currently standing at some 320 per annum — and the report expects the number to increase before the peak is reached.

The asbestos industry makes no pretence of being pleased about the December 1980 deadline for enforcing the 0.5 fibre per mille limit for amosite. Mr S D Hardie of Turner and Newall and an advisory committee member says that the deadline is too tight. He insists that working to 0.5 fibres per mille is pushing the technology to its limit. The industry, he says, can work to one fibre per mille of chrysotile but, as far as the 0.5 fibre per mille for amosite is concerned, Hardie says he could not "put his hand on his heart and say to the work force that it is not being exceeded".

Criticism that the advisory committee has been too sensitive to the needs of industry has been voiced by the Society for the Prevention of Asbestos and Industrial Diseases. Mr Max Madden, a trustee of the society and former Labour MP for Sowerby — a constituency which includes the ACRE Mill asbestos factory at Hebden Bridge — was frank about the pressure on the advisory committee. In his view, the committee had been subjected to considerable propaganda from the industry and some of it had succeeded. Anticipating criticism of its report, ACA chairman Bill Simpson emphasised that the control limits are not a "once and for all" exercise. New evidence will be constantly reviewed, and every encouragement was being given to the development of safe asbestos substitutes.

Comments on the report are invited and should be submitted by 31 January 1980.

$40 billion law suit over Dioxin damage: A veteran of the Vietnam War is suing five US chemical companies for $40 billion damages, claiming that he suffered from brain cancer as a result of exposure to the defoliant 2, 4, 5-T, known as Agent Orange. The defoliant was used extensively by the US in Vietnam between 1962 and 1971, and recent studies have indicated that its use as a domestic herbicide may be associated with foetal defects in pregnant women. According to the man's attorney, the purpose of the suit is "to establish a trust fund to help the veterans who discover they have been poisoned after the statute of limitation runs out, and for the children yet unborn who will have birth defects".

Waste disposal problems halt radioactive research: Research workers at Harvard University have been told that research involving the use of radioactive tracers will have to be stopped because of difficulties in the disposal of radioactive waste. This follows the closure last week of the US's two main dumping sites for liquid low-level radioactive waste, Hanford in Washington state, and Beatty in Nevada. A third dumping site, Barnwell in South Carolina, refused to accept such wastes last spring.

Many major laboratories and hospitals are now faced with mounting accumulations of liquid waste which will have to be stored until alternative disposal arrangements can be made. The government is considering creating new temporary disposal sites or using the six national laboratories operated by the Department of Energy as temporary dumps. Another alternative could be the incineration or evaporation of the waste products. NIH disposes of its absorbed wastes in this fashion under an agreement with Todd Shipyards in Galveston, Texas. According to Dr Mortimer Litt of Harvard, an insignificant amount of radiation is released by this process, well below the exposure standards established by the Nuclear Regulatory Commission, and would not constitute a public health risk. — *Anne Norman.*

Israeli drought threatens Dead Sea: Israel faces water rationing by next summer, unless there is an exceptionally wet winter to replenish the Sea of Galilee — the main reservoir of the country — now at an all-time low. This year's severe drought will not only have a severe effect on the country's agriculture and industry, it has also caused severe damage to the ecology of the Dead Sea, which gets 65% of its water from the Sea of Galilee via the lower Jordan. Several Israeli scientists are demanding urgent government action on the long-discussed proposal to construct a canal from the Mediterranean to the Dead Sea. Dr Sholomo Drori, Information Officer of the Dead Sea Potash Works at S'dom, told *Nature*: "No one is putting pressure on the government for the important things, like a canal from the Mediterranean to the Dead Sea. The Southern part of the Dead Sea has vanished, probably for ever".

Professor Anthony Peranio of the Technion, renowned for his interest in renewable energy sources, said: "We should be building this canal. There should be great pressure brought to bear on the powers that be to get free-flowing water from the Mediterranean to the Dead Sea." Because the Dead Sea lies some 600 metres below the level of the Mediterranean, the canal, he said, could be harnessed for energy purposes, to generate electricity and cool inland power stations.

First French cosmonaut to be trained next year: Franco-Soviet space cooperation has taken a step forward with the announcement on 23 October that a French astronaut will be part of the crew of a Soviet spacecraft to be launched in the middle of 1982. This follows a meeting on space cooperation — the sixteenth such meeting in 30 years between France and the Soviet Union — in Corsica from 15 to 20 October. The meeting also agreed on details of a study of the atmosphere of Venus and reviewed the possibility of cooperation in biology, geophysics, meteorology and telecommunications.

"Truth in testing" legislation defeated in US: A bill requiring disclosure of the methods used by the companies which set and administer standardised educational tests has been defeated in the US Congress after an intensive lobbying effort by the testing industry. Tests such as the standard aptitude test (SAT) are set and administered by largely unregulated private firms. The tests determine the education of most American children from assignment to classes for the mentally retarded to college entrance, and are enormously influential. The so-called "truth in testing" legislation would have required (among other things) that the companies disclose examination questions. Higher education organisations and testing companies opposed the bill, claiming that disclosure would result in undue influence on school curricula. They also said it would be prohibitively expensive to prepare new questions for every exam and that the quality of questions would suffer. A proponent of the bill, Dan Cameron of the National Education Association, questioned the industry's motives. "The testing industry exerted all the influence it has to kill this legislation because they don't want to reveal what this legislation would make them reveal", he said.

● The industry suffered a defeat last week when a Federal judge ruled that standardised tests could not be used by California officials to determine the placement of black children in classes for the mentally retarded (*Nature* 25 October).

ISTC planners accused of illegal lobbying: Administration officials may have acted illegally by using funds appropriated by the US Congress to gather support from private individuals and institutions for the proposed Institute for Scientific and Technological Cooperation (ISTC), according to a report prepared by investigators for the Senate Appropriations Committee. The accusations have been passed on to the Department of Justice, and they could be the death-blow for the Institute, a centre piece of the US presentation at the United Nations Conference on Science and Technology for Development. The ISTC is now struggling desperately for congressional approval.

Three weeks ago, the US Senate agreed by 70 votes to 22 to cut all funds for the Institute out of the Foreign Aid Appropriations Bill. This was largely at the instigation of Senator Dennis Deconcini of Arizona, who earlier in the year had persuaded the Senate not to approve the ISTC's authorisation on the grounds that it would merely create another unnecessary government bureaucracy. The latter decision was later overturned in a conference with the House, and it had been hoped that the budget decision would also be reversed, since the House has already agreed to provide $23.75 million of new funds for the Institute. However the latest findings about the ISTC's lobbying activities have not increased its chances of success.

New crack in French reactor increases hazard: A further step in the crisis of the French nuclear programme has occurred with the revelation that there has been a leak of primary coolant into the secondary steam-generation circuit at the operational nuclear reactor Bugey-2 near Lyons. This was confirmed last week by the French trade union federation, the CFDT and is exactly what was feared might happen after the discovery of cracks, at 25 of France's 26 pressurised water reactors. The cracks were in the tubular collars that are supposed to seal off the radioactive primary coolant from the water circulating in the steam-generation areas (*Nature* 27 September) and mean that large sections of the reactor are now subject to radioactive contamination. The original discovery of cracks has already led to a strike and consequent postponement of the loading of two newly-built reactors (*Nature* 11 October). This time the state-run Electricité de France has refused to shut down the Bugey plant and has declared a moratorium on all public information unless previously cleared by government authorities. — *Jim Ritter.*

Portrait of the out-of-work scientist

Government expenditure cuts are just statistics to some; to others they mean personal and professional tragedy. **Joe Schwartz** reports on those who are fighting back

Dr Anne Simmonds is an internationally known research biochemist specialising in purine metabolism. Forceful and competent, her problems as director of the Purine Laboratory of Guy's Hospital Medical School in London for the past eight years include convincing granting agencies that the study of a metabolism is as important as studies of specific diseases.

The field is a lively one. Studies of the loss of enzymatic links in the purine recycling process make specific interventions possible for at least five bizarre and life-threatening clinical abnormalities. One of these is the Lesch-Nyhan syndrome, a severe neurological disorder in children characterised by spasticity and self-mutilation which is due to a defect in one of the salvage enzymes of the purine cycle.

Simmonds' work, in conjunction with clinical colleagues, has led to her being "in the right place, at the right time, with the right expertise to be able to recognise a new disease for the first time". Her busy schedule includes the activities associated with an established international researcher: apointment to the Organising Committee for the Second and Third World Congress on Purine Metbolism in Man, invited participant from the UK to the Second World Symposium on Inborn Errors and Immune Disease in New York, and an appointment as Visiting Professor in the Department of Medicine at the University of Munich for a period early in 1980. Professor Fred Rosen of the Department of Pediatrics of Harvard Medical School describes the field as "bursting with excitement" and acknowledges Simmonds as having done "well known and very fine work with very widespread implications".

In September 1980, the Purine Laboratory will be closed and its Director, along with her staff of 4 graduates and one doctoral student will be unemployed.

Anne Simmonds is one of many senior researchers in the UK with international reputations and a long history of successful and productive research who are slowly being squeezed out of their research careers. Simmonds is vulnerable because she has moved through a succession of short-term contracts, the 'soft money' of the 60s, in order to be able to do her work. In the present period, research councils have found it convenient to regard short-term contract workers as dispensable and with 50% to 70% of the UK's basic research workers being supported by contracts researchers like Simmonds are caught in the net.

Simmonds' case is an important counter-example to official rhetoric about the effects of cuts on research programmes. Contract workers are protrayed as 'young and adaptable' or as old and 'burned out'. Official talk about the need to 'make room for new blood' or to 'maintain excellence' has muted criticism of recent policy decisions, by making a virtue out of the perceived necessity to cut public spending. Senior researchers who are unfortunate enough to find themselves in vulnerable positions have not only to face the loss of their jobs but also attacks on their competence for no longer being 'good enough' to warrant support.

Simmonds stresses that many scientists working in research full time on contracts have voluntarily given up other permanent jobs because of their commitment to research. In her case, she has turned down three permanent clinical jobs as well as a position at the Wellcome Laboratory in Beckenham. Her refusal of the Beckenham job ilustrates some of the problems facing researchers in the UK. Simmonds was hired in 1967 at the Wellcome to do purine research. But in 1970 Wellcome decided to transfer most of its purine programme to the US. Simmonds was offered a chance to go on to Wellcome's permanent staff but after accepting she found that the UK purine programme was being eliminated and that she would be required to work in immunology instead.

Through the intervention of Dr David Long, then Director of the Wellcome, and with funds provided, in true 19th century style, by an anonymous donor, Simmonds was able to set up a purine lab at Guy's in 1971. Her support from Wellcome stopped in 1972. She has since received a 3-year non-renewable contract from the MRC with the MRC making it "very plain" that they were not happy about a person of "advanced age (43 at the time) not having a permanent position." She was able to get a final three year bringing grant from the Wellcome in 1977 and with its termination in 1980 the work at Guy's will stop.

Simmonds has applied to "every conceivable" charity for funding from EEC funding agencies to the Cadbury, the Sainsbury and the Kellog foundations. She has not reapplied to the MRC. "If I was too old for them then, I am too old for them now. The MRC has always been less than helpful and we have either been ignored or forced to listen to insults about our capacity to research." As Simmonds puts it: "Because we have found it impossible to continue to do our work well under current pressures, we have dared to question our traditional role — and we have rocked the boat".

The MRC says that their records show that Simmonds had applied for and received a normal three year non-renewable grant in 1974 and has not applied since then. "The MRC has no concerns in this particular situation. She can apply for a grant as can everyone else and whether she does or not is entirely up to her. This is a matter for Guy's Hospital, not us", an MRC official told *Nature*. The loss of Simmonds lab means that there will be no work of international stature on purine metabolism in the UK.

Simmonds has had the energy and commitment to fight these pressures organisationally. She is one of the founding members of ARMS (Assosiation of Researchers in Medical Science) established in June 1978. "I was originally concerned because of the general problems facing staff: short term contracts, the loss of two years in every five or six writing and rewriting applications and the loss of younger people just when they have learned enough to be useful."

ARMS now has branches in both London and Manchester. It is attempting convince UK authorities that a career structure for non-medically qualified full time researchers is a long overdue necessity for the health of British medical research.

Simmonds describes her involvement in ARMS' campaign in personal terms: "Two of my senior colleagues with outstanding records, who, when ARMS was set up last year had 12 months left, are now out of work. This had happened despite the fact that they have actively contested their abandonment by the MRC after 13 years of short term support, both to that body and

to local authorities. Today I am in exactly the same position. I have one year left and my staff will have to follow me into the street since the school will not support them beyond the termination of my own grant." Simmonds intends to devote her political energies in the coming year to collecting data on the current treatment of senior scientists like herself. As far as her research goes she is more philosphical. "Although it is difficult to believe that there is no official recognition when one has done something as clinically useful as describing a new disease, we have to accept that we are in the wrong field with the wrong qualifications." □

Where MRC stands on jobs

THE Medical Research Council's current career structure for non-clinical scientific staff was agreed with the Association of University Teachers and came into force in 1974. It applies only to staff in the MRC's units and provides for three categories of appointment: three-year short term contracts, five year limited term appointments and tenured posts.

In general a new PhD would apply first for a three-year short term contract. At the age of about 27, after completing one three year term, he/she would then eligible to apply for a five year limited term appointment. At the end of that, at age about 31, he/she can apply for tenure.

The five year limited term appointment was created as a bridge between post-doctoral appointments supported by short term grants and tenured posts. The idea was that 75% of those with limited term appointments would receive tenure at the end of five years. Those who did not, would not normally be eligible for further three or five year appointments. This scheme was designed to prevent researchers continuing work on limited term grants into middle age by forcing them into a career decision in their early thirties.

The MRC currently employes 790 non-clinical scientific staff in its units. 21% of them are on short term contracts, 14% on limited term and 65% have unlimited tenure. The target figures, which the Council would hope to achieve after the system had been working for several years, are 18%, 15% and 67% respectively. However, with pressure on budgets due to public expenditure cuts, the MRC may never achieve these figures. It has recently been rethinking the career structure for non-clinical scientific staff and has put forward a proposal to the AUT for negotiation, which is likely to include a major modification of the tenure system.

The position in the universities is very different. The MRC provides tenured staff with grants for research projects. Untenured staff are paid out of these grants, the university being their employer. The MRC currently provides funds for 800-900 research studentships and 1300-1400 scientists on short term contracts. Half of the latter have PhDs and half have only first degrees.

Seven years ago, the MRC began to realise the problem of absorbing all these short term contract workers into permanent positions. It has, however, according to one official been surprised at how slow the crisis has been in coming. Many people have left the system by taking jobs overseas or moving right out of research. "The problem (of short term contract workers) will solve itself by the scientists making an appreciation themselves and then making the necessary adjustments". However, the Council does not know how far the process of adaptation has gone and criticises the AUT's attempts to quantify the problems. "The (AUT's) figure of 2500 unemployed scientists hasn't been substantiated and we don't really know if there is a problem, whether people have been able to adapt and whether able people have been discouraged from entering research".

The MRC's main response to the lack of tenured posts has been to create bridging fellowships to enable the "truly able" post-doctoral worker to wait longer than the normal five year limited term for the right tenured position to turn up. But the scheme has met with minimal response. The Council has also resisted pressure from within its own ranks and outside to recruit more graduate students.

Ideally, the MRC would like to have more control over research posts. Two MRC officials at least would like to judge the "hallowedness and timeliness" of research and to see a "population of mobile research workers who could move around at the Council's discretion". Another, Tony Vickers, told a meeting at the Royal Society of Medicine earlier this year that "it might not be a bad idea if we had to revert to immediate post-war conditions". This would mean a much smaller scale of scientific activity with no post-doctoral researchers. "Serendipity goes out of the window when postdoctoral workers come in".

The Association of Scientific, Technical and Managerial Staffs has been trying for several years to gain 50% membership on the MRC. Its attempts, however, have been resisted. It just wants "to turn Council into a private benefit society" according to one MRC official. "The Council is a self-perpetuating oligarchy" which has trust in its members who in turn have trust in it.

ASTMS, however, takes a different view. It considers fixed term contracts as a "primitive way of dealing with scientific and technical staff" which places "too much power in the hands of incompetent employers at a time of particular difficulties in scientific employment".

Judy Redfearn

SRC: university cuts are the greatest threat

"The science vote is not being harshly treated" by the Conservative government in the latest round of public expenditure cuts, according to Sir Geoffrey Allen, Chairman of the UK Science Research Council. There is a good case for maintaining a reasonable budget for research, he says, and this is having a strong influence on the government. The science budget is therefore unlikely to suffer the massive percentage cuts proposed for other areas of public expenditure such as education and many of the social services.

The SRC budget is to be cut by only 1½% in real terms in the current financial year and a further 2% in 1980-81. The lack of budget guidelines after 1981, however, is causing problems with medium term planning. For example, the Council's recently announced programmes in post graduate education to improve the performance of graduates in industry (*Nature* 2 August, page 347) are to receive priority over the next few years — but uncertainty in future budgets means that the rate of expansion of the programmes cannot be planned in advance.

Similarly, the SRC cannot plan space and astronomy beyond the end of the current programme in 1983. International collaboration may be one way of cutting costs, says Sir Geoffrey.

The greatest threat to the level of science funding in the UK, however, probably comes from the recently announced cuts in the universities budgets. "These are bound to affect science and engineering", says Sir Geoffrey especially in the short term when running costs will be squeezed. In the long term science and engineering will be cut proportionately less than other faculties and will therefore make a greater part of a smaller whole. "This could be good from our point of view. The government is saying that we've got to be more selective. This means either fewer universities or a smaller overall staff maintaining quality".

Sir Geoffrey hopes that the problem of providing employment for scientists (and coping with any redundancies the universities may have to make) will be helped by the SRC's research felowship scheme whereby senior scientists can vacate tenured posts by taking up SRC fellowship. "We have the money to do this on a small scale".

Sir Geoffrey's belief in the government's empathy for research was endorsed by the Prime Minister, Mrs Margaret Thatcher, herself last week when she told members of the Chemical Society of her committment to basic research at a ceremony to award her with the Society's Honorary Fellowship. "One must listen to the voices of scientists and pay attention to what they say", she said. □

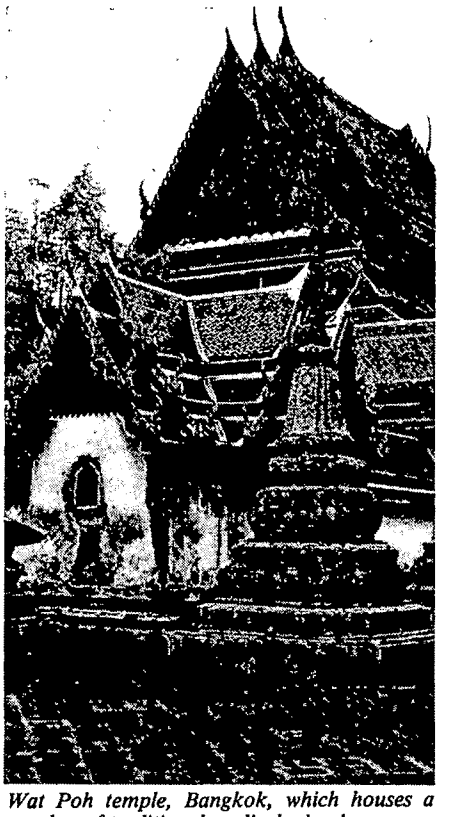
Thais put their faith in folk medicine

In first of two articles on scientific issues in Thailand, **David Bousfield** of the University of Sussex describes how religion and medicine often go hand in hand



TRADITIONAL health care systems based on herbal preparations still exist in many developing countries today, and although often despised in the recent past they could provide a focus for the development of local pharmaceutical industries and research. Plants are already important sources of established drugs such as diosgenin (a precursor of many steroids), codeine and atropine. They may also contain compounds with novel actions. The massive screening of plant extracts for anti-cancer drugs carried out under the auspices of the National Cancer Institute, and the research currently being coordinated by the World Health Organisation on physiological bases of folklore contraceptives are good examples of the current interest in this field. In addition, by employing an indigenous health care structure, medical treatment may begin to penetrate rural areas where previously there was no help at all.

South-east Asia provides some useful examples of the possibilities and limitations of integrating this traditional knowledge with the medical needs of a developing society.

In Bangkok alone there are more than fifteen traditional medical schools, some of which can be found on the grounds of Buddhist temples. Wat Poh, the temple of the Reclining Buddha, for example, has long been an important centre for folk medicine in Thailand. In the provinces, such as Chiang Mai in the north, herbal pharmacies are common and are often found beside, or even inside, their modern counterparts.

Certain Buddhist monks, the 'maw phra' or 'doctor bhikku', play an important role in treating rural sick. In some cases these schemes can be very ambitious. The Abbot, Phra Chamroon Parn Chan, of the temple Wat Tham Krabok has recently been given the Ramon Magsaysay Award (a south-east Asian equivalent of a Nobel Prize, named after the late Filipino President) for his work with drug addicts. His approach relies heavily on herbal infusions "to clear poisonous drug residues from the body", thus eliminating "the physical desire for narcotics". With government subsidies the Phra hopes to be able to treat up to 4,000 addicts annually.

Doctor Bhikkus self-trained bare-foot 'tambol' doctors are very popular among the lower educated, lower income groups in both rural and urban districts. Several government training schemes are in existence which aim to improve this service in areas such as nutrition and family planning. Use of herbal medicines is taught in many university departments of pharmacy and pharmacology, and in some cases students may even attend additional courses at their local traditional school of medicine.

Wat Poh temple, Bangkok, which houses a number of traditional medical schools

Research is well under way on the extraction, identification and characterisation of the physiological, pharmacological and toxicological properties of the active principles present in a number of crude drugs. Particular areas of interest include the studies of alkaloids present in local *Rauwolfia* species, some of which could provide a commercial source of drugs such as reserpine. 'Kinchai', Chinese celery (*Anium graveolens*), is also being studied for its potent hypotensive actions and its dramatic ability to reduce temporarily sperm count in man. In Chiang Mai research is being carried out on extracts from a variety of plants including a *Curcuma* (Zingiberaceae), locally known as 'Wan Ngu'. This contains an inhibitor of cobra and viper neurotoxin, and the study of the properties of this extract and its active ingredients has stimulated an exciting amount of neurophysiological and neuropharmacological research. The universities of Mahidol and Chulalongkoru in Bangkok are carrying out even more intensive studies.

The development of useful drugs based on natural product 'diospyrol' serves as a good example. Roundworms, hookworms and other parasitic infections are a serious health problem throughout south-east Asia. In Bangkok's slums 2% of the children have *Ascaris* infections and 6% hookworm. In rural areas the prevalence of hookworm can exceed 80%, with anaemic complications in half the cases. Effective drugs for treatment do, of course, exist but are often unavailable in the more remote parts of the country. On the other hand, the tree 'Ma-gluea' (*Diospyros mollis*, Griff) which is indigenous to northern and central Thailand has long been recognised for the anthelminthic activity of its berries. The fresh fruit is crushed with a small amount of water, strained, and mixed with coconut water to mask its disagreeable taste.

Clinical trials have shown that the drug is effective against a wide variety of intestinal parasites, and the limited field testing which has been carried out has met with encouraging results. The plant, however, only bears fruit in the rainy season (June to October) and the remedy is only effective if the berries are fresh. A good deal of work, conducted mainly by the Ministry of Public Health in collaboration with Japan, has therefore gone into identifying the active principle, 'diospyrol', a methylated binaphthyl compound, and to discovering methods of preserving the extract. This work was completed in the late 1960s, but since then little has been done to develop herbal medicines to a commercial level.

Research into natural products and herbal medicines is being carried out on a similar scale in at least nine neighbouring countries. These are Thailand's four partners in ASEAN — Indonesia, Malaysia, Singapore and the Philippines — plus Japan, Korea, Hong Kong, Australia and New Zealand. Together they make up the Network for the Chemistry of Natural Products in South East Asia, a Bangkok-based organisation funded mainly by UNESCO and the Japanese government. It is, however, clear that serious problems occur whenever the commercial exploitation of a natural product medicine becomes a possibility.

Ironically this may be the result of the United Nations Industrial Development Organisation (UNIDO) plan for the establishment of drug industries in Third World countries, which involves a backward integration approach to drug manufacture. UNIDO feels that each country should begin with setting up packaging plants, then move on to formulation of imported bulk drugs, and finally manufactures the bulk drugs themselves. But in countries such as Thailand such an approach could stifle the motivation behind much of the current research into herbal medicines and result in many of these new compounds being developed and sold by the multinational pharmaceutical companies. □

Population boom blunts Pakistan's self-sufficiency drive

Despite Pakistan's efforts to become self-sufficient in food grain, it is still falling short of the target every year. The resulting heavy expenditure on the import of wheat, the staple foodstuff, is compounded by considerable congestion at the port of Karachi and in trains carrying the millions of tons of wheat grain upcountry. The whole economy of Pakistan is suffering in consequence. Last year, for example, wheat created a crisis when the country had a bad harvest and imports rose to 2.3 million tons. The problem is not that production strategy is failing for a valid reason — such as targets being unrealistic or the potential being weak — but that the mechanism is inefficient and the will is missing for many imperative measures. These include the package of improved technology for different areas of Pakistan (a target now well within reach) and a streamlining of the distribution of seeds, fertilizers, pesticides and water to the farmer.

At the International Seminar on Wheat held in Islamabad last August, Dr Norman Borlaug, the Nobel laureate, said that at present only one-third of Pakistan's potential wheat production is being exploited. Borlaug, who has been intimately associated with the Green Revolution in Pakistan, blamed the existing official apparatus both for neglecting to apply the available improved technology to wheat production, and for the continued short-sighted reliance upon food aid and concessional purchases (under easy payment contracts from friendly countries, such as the US PL-480).

The pity is that Pakistan also happens to be one of the few countries that staged the Green Revolution early, in the mid-1960s. It had such tempo and potential that Borlaug at that time not only forecast self-sufficiency in food grain within a few years time, but also called Pakistan the 'Mexico of Asia', visualising that it would be exporting wheat and rice to other countries sooner than many imagined. Borlaug's dream was never realised; and sooner than elsewhere, the Green Revolution tapered off.

This is clearly borne out by the wheat production figures since 1965, when the dwarf, high-yield seeds from Mexico became available for commercial sowing.

It can be seen from the accompanying table that wheat production, after nearly doubling from 3.75 million tons in 1965 to 7.10 in 1969, has almost flattened off during the course of the last decade — last year even showing an alarming dip.

Self-sufficiency in wheat could have been attained, even with the very modest increase recorded in the last ten years, but for two inhibiting factors. One is the population explosion, running at a 3% per annum, a result of the slowly growing standard of living. The *per capita* daily wheat consumption has risen from 244 to 340 g during the last 10 years. Even with a record wheat harvest of almost 10 million tons this year, a short-fall of 0.6 million tons is still possible.

There is however hope that, unless the political situation deteriorates further, Pakistan may now be able to turn the corner. The new factor is a drastic reorganisation of the Pakistan Agricultural Research Council (PARC), which has turned it into a fully autonomous organisation with wide powers of planning, coordination, financing and formulating national strategy for agricultural research. The PARC now has a full-time chairman, with the status of secretary to the government. It is also intended that the should be a scientist of high repute and not a politician. The present chairman, Dr Amir Muhammad, has gained the necessary experience and expertise to organise research on a national level through his previous positions as Vice-chancellor of an agricultural university and Director of the Atomic Energy Agricultural Research Institute.

The PARC is now equipped to provide leadership to other research organisations in the field. This is particularly significant in Pakistan, where agricultural research has largely been fragmented at the provincial level and has lacked direction. This was all too manifest last year in the wheat production debacle. Farmers had sown considerable amounts of wheat varieties that were susceptible to disease, even though disease-resistant types could have been easily identified and the farmer suitably advised — if the research organisations and their provincial extension services had been alive to the situation.

This year's 20% increase in wheat output is partly due to the PARC reorganisation, and partly to the federal government itself. After recovering from the panic of having to import 2.3 million tons of wheat, and paying the heavy price, the government is now taking an active interest.

The PARC has started taking such vital steps as zoning the country for some of the major crops in terms of agro-ecological variations, sending its research teams in different zones to conduct investigations and research on the spot, and providing analytical service facilities not available at the provincial institutes. But its most significant achievement appears to be the establishment of properly constituted National Agricultural Research Centre near Islamabad. A staff of 25 scientists, eight of them postdoctoral, are already working at the centre, with another 40 in the process of recruitment. The emphasis is on high calibre to strengthen the team.

The centre has already mounted a large number of experiments on its own fields (which cover 1,500 acres) involving topics such as plant genetics, agronomy, and plant pathology. It is also investigating the 'package technology' of producing different grains for different areas. Each package will contain information on varieties, cultural practices, fertilizers, weed control, harvesting, and storage.

Genetic resources conservation is another vital responsibility of the centre. It has already collected thousands of exotic, as well as local, varieties of wheat, rice, triticale, maize and other grains. They will be preserved for up to 100 years in the main depository, in vacuum at 0°C. To mount an effective genetic variety programme, the breeding stock should have great genetic diversity; breeders all over the world have started to feel the pinch of starvation as new sources of genetic diversity are getting scarce, squeezed out by the rapidly spreading improved crop plant varieties.

Azim Kidwai

Table 1 Pakistan wheat production since 1965

Year	Wheat output (millions of tons)	Imports (millions of tons)	Population (millions; approximate)
1965	3.75	Not known	5.5
1968	6.50	0.015	
1969	7.10	0.123	
1971	6.78	0.439	6.5
1974	7.50	1.179	
1976	8.55	2.300	
1977	9.00	1.087	
1978	8.15	2.300	7.5
1979	9.99	Not yet known

Probing the insulin receptor

from P. H. Sönksen

THE German Wool Research Institute houses some of the foremost peptide chemists in the world who sharpen their teeth on insulin as a simple chemical model for the more complicated molecules that will be keeping us warm in the months to come. At the Institute two young students, Peter Thamm and Achim Schüttler have respectively synthesised a family of specifically photolabelled insulin analogues and made a variety of specific covalently-linked insulin dimers which together have led directly to major developments in our knowledge of the insulin receptor. The insulin receptor was perhaps the most popular subject at the International Insulin Conference* held at the Institute recently.

Remarkably concordant results on its composition were provided by three independent groups. M.H. Wisher and colleagues (St Thomas's Hospital Medical School, London) have specifically covalently labelled a membrane protein of approximately 300,000 molecular weight which can be resolved into a subunit of apparent molecular weight 130,000. This polypeptide runs atypically on polyacrylamide gels and may be a glycoprotein of true molecular weight nearer 90,000. Rather surprisingly this same membrane component was readily and specifically labelled with probes carrying the photoreactive group in the A_1, B_1 or B_{29} positions.

These observations were exactly in keeping with those of C. Yip (University of Toronto) working independently with similar but less specifically photolabelled probes. Yip reported two specifically labelled components (130,000 and 90,000 molecular weight) in membrane extracts from insulin-responsive cells but only the 130,000 molecular weight components in extracts of cells containing insulin binding sites but no insulin-responsiveness (such as brain) and went on to suggest that the 90,000 component may be an effector molecule. M.P. Czech (Brown University, Rhode Island) using a bifunctional cross-linking reagent was able to produce almost identical results by covalently linking radiolabelled insulin to the membrane receptor after the two had been allowed to react *in vitro*. He, like Wisher, had also isolated a 300,000 molecular weight component that could be dissociated into 125,000 molecular weight subunits after reduction of disulphide bonds. Early results from C. Diaconescu and D. Saunders (DWI) and A.R. Rees (University of Oxford) suggest that covalent linkage of insulin to its receptor in adipocytes may lead to prolonged activation of insulin-dependent processes.

Other remarkable observations on function of the receptor come from the synthetic dimers (Schüttler). They show considerable discrepancy between receptor-binding activity (100%) and biological activity (considerably impaired, 0–60% depending on assay). P. De Meyts (Institute of Cellular and Molecular Pathology, Brussels) and colleagues concluded, on the basis of their studies with these dimers, that each monomeric half of the dimers might bind to a component of the insulin receptor and in some way prevent activation (possibly by inhibiting subsequent conformational change). On the other hand K. Willey and colleagues (St Thomas's Hospital Medical School, London) felt that their own results were compatible with the simpler concept of dimer reaction through one component only.

Other examples of the important contribution made by the synthetic chemists include some very elegant experiments reported by A.S. Rosenthal (Merck Sharp and Dohme Research Laboratories, New Jersey).

In the presence of synthetic peptide fragments of insulin, ^{3}H-thymidine incorporation into lymphocyte DNA as a measure of T cell response, was used to delineate the specificity of the phenomenon. In one strain of guinea pigs

*The 2nd International Insulin Symposium was held at the Deutsches Wollforschungsinstitut, Aachen on 4-7 September, 1979, and organised by Professor H. Zahn and Dr Dietrich Brandenburg.

P.H. Sönksen is Professor of Endocrinology, St Thomas's Hospital Medical School, London.

More on anthropoid origins

from Peter Andrews

THE origin of the higher primates is a contentious issue at present. Traditional interpretations place the tarsier closest to the anthropoid primates but an alternative to this has been advocated for some years by P.D. Gingerich of the University of Michigan. Gingerich has demonstrated a nearly continuous series of fossil primates from the early Eocene to the Oligocene all belonging to the family Adapidae (for a review see *J. hum. Evol.* **6**, 483; 1977), and he has shown that these become adaptively similar with time to early anthropoids.

In this issue of *Nature* (page 65) a group of Burmese and American anthropologists have described a new specimen of fossil primate from the late Eocene of Burma. This is named *Pondaungia cotteri*, and it possesses a number of specialisations that suggest it had reached the anthropoid grade, specialisations such as the great depth of the lower jaw, and the cusp and wear patterns of the teeth. These specialisations are overlaid on a pre-anthropoid pattern that seems to be most similar to the generalised adapids of Europe and Asia that Gingerich advocates as the immediate precursors of the Anthropoidea, and if these conclusions are substantiated by further discoveries it might well be possible to locate the origin of the anthropoids in the late Eocene of Asia. Work is continuing in Burma, and it is to be hoped that Ba Maw and Russell Ciochon will find additional specimens.

By the middle of the succeeding period, the Oligocene, anthropoid primates are represented by a number of species in the Egyptian Fayum deposits, which are currently being excavated by Elwyn Simons of Duke University, and by the end of the Oligocene they are also known in tropical Africa. They diversified during the succeeding periods up to the present, giving rise to all the living species of monkeys and apes and man. The adapids on the other hand diminished in numbers after the end of the Eocene, with the latest known population occurring in 10 million year old deposits in India and Pakistan where they apparently existed as a relic population (described earlier this year by Gingerich in *Nature* **279**, 415; 1979).

Peter Andrews is in the Department of Palaeontology, British Museum (Natural History).

T cell response could be localised to a few amino acids around the tenth residue of the B chain. On the other hand the specificity of antibodies produced by these animals did not reflect the specific determinants unique to the insulin used for immunisation. This distinction between T cell response determinants and specificity at the serum antibody or B cell level was also shown in mice. □

Nuclear quadrupole resonance at Toulouse

from J.A.S. Smith

P. GRIVIT (Université de Paris), in whose laboratory the first nuclear quadrupole resonance experiments in France were conducted, opened the conference*. He reviewed in masterly fashion the many current applications at Orsay of nuclear quadrupole interactions to solid state physics, concluding with the description of a sensitive pulsed spectrometer designed by L. Guibé and his coworkers (Paris, Orsay), a feature of which was its highly automated operation. This theme was repeated in several other papers, notably from E.A.C. Lucken's group (University of Geneva) who described a pulsed FT spectrometer for the study of single crystals, from which the complete electric field gradient tensor may be derived under computer control. Other workers described frequency and phase-locked spectrometers for the determination of true line shapes (P.T. Narasimhan, Indian Institute of Technology, Kanpur) and a special pulsed coil system for detecting ^{14}N signals from samples external to the spectrometer (T. Hirschfeld & S.M. Klainer, University of California, Berkeley) with potential applications to geochemistry. A recent development, the derivation of nuclear quadrupole interactions in free radicals by ENDOR experiments, was described by A. Colligiani (CNR Quantum Chemistry Laboratory, Pisa), who reported the first measurement of the full ^{2}H quadrupole coupling tensor in the free radical $HOOC.\dot{C}D.COO^{-}$.

The applications of nuclear quadrupole resonance to transition metal chemistry were emphasised. T.B Brill (University of Delaware,) described the applications of ^{55}Mn quadrupole resonance to the study of the electronic structure of tricarbonylcyclohexadienylmanganese(I) and its substituted analogues, and other speakers discussed ^{63}Cu resonance in diamagnetic copper(II) complexes (T. Okuda & A. Weiss, Technical High School, Darmstadt), ^{35}Cl quadrupole resonance in mercury pentachlorocyclopentadienes (G. Wulfsberg and coworkers, St John's University, Collegeville, Minnesota), in some hexachloroplatinates (IV) hexahydrates (A. Sasane, Shinshu University, Japan), and Zeeman studies of ^{63}Cu resonance in single crystals of Cu(I) triphenylphosphine dimers (H. Negita *et al.* Hiroshima University, Japan). Although it has been known for some time that quadrupole resonance of ligand nuclei can be readily studied in paramagnetic complexes, for example ^{14}N quadrupole resonance in dichloro (dimethylnitrosoamine) copper (II) (D. Nakamura, Nagoya University, Japan), T.J. Bastow and H.J. Whitfield (CSIRO, Clayton, Australia) showed in their paper that strong ^{63}Cu signals can be detected in several paramagnetic Cu(II) salts such as $CuCl_2$ and $CuBr_2$; the signals are seen because of strong exchange narrowing, with widths of about 35 kHz, little different from that of ^{63}Cu resonance in diamagnetic Cu_2O. In a review of recent studies of inorganic coordination compounds, T.L. Brown (University of Illinois) discussed the wealth of information now forthcoming from solid complexes by a combination of conventional cw and pulsed measurements with double resonance techniques.

The remarkable increase in sensitivity afforded by double resonance experiments was emphasised by many speakers. For ^{2}H and ^{14}N, the technique is now well established; J.L. Ragle (University of Massachusetts, Amherst) demonstrated the usefulness of ^{2}H quadrupole resonance in a study of pyridine and its salts, and ^{14}N double resonance was applied by M. Garcia (Queen Elizabeth College, London) to many imidazole derivatives and by A. Loetz and J. Voitländer (University of Munich) to a series of amidinium salts. Three papers were devoted to another recent development of double resonance spectroscopy, that of the detection of ^{17}O quadrupole resonance signals in natural abundance; J.A.S. Smith (Queen Elizabeth College, London) and S.G.P. Brosnan and D.T. Edmonds (University of Oxford) discussed the novel features of such methods applied to compounds containing -O-H groups, the most important of which is the appearance of dipolar structure, and O. Lumpkin (University of California, San Diego) described its applications to compounds containing O-O bonds, such as $IrO_2Cl(CO)(PO_3)_2$ a reversible oxygen carrier. In a later paper, P.J. Bray (Brown University, Rhode Island) demonstrated very clearly the significance of ^{14}N quadrupole coupling constants as a measure of biological activity, for example in the bateriostatic activity of the sulphanilamides and the tumour-inhibiting properties of several nitrogen mustards.

Studies of phase transitions and molecular motion in solids were common themes of a number of papers. J.R. Brookeman (University of Florida) gave a timely review of the importance of measurements of the resonance frequency and relaxation times close to phase transitions and several other papers discussed the temperature dependence of the same quantities for example, in hydrazine derivatives (Y. Abe, University of Tsukuba, Japan), in some bromocyclotriphosphazatrienes (A.L. Porte, University of Glasgow) and in ammonium salts such as α-NH_4HgCl_3 and NH_4ReO_4 (H. Chihara, Osaka University, Japan) in which the anomalous temperature coefficients were interpreted by taking into account the finite jump-time of the NH_4^+ ion between its equilibrium configurations. There was increasing interest in the value of variable pressure studies in studying solid-state processes; R.J.C. Brown (Queen's University, Kingston, Canada) stressed the generality of the relationship between the temperature and pressure coefficients of the quadrupole resonance frequency and J. Stankowski (Poznań, Poland) studied ^{75}As resonance in $K D_2AsO_4$ up to 3kbar as a test of current theories of proton-ordering in this crystal. I.G. Shaposhnikov (Perm, USSR) discussed a new theoretical attempt to analyse the 'Bayer' problem, the temperature variation of the quadrupole spin-lattice relaxation time, T_{1Q}, due to random thermal oscillations, by the methods of quantum kinetics; his theory shows that significant departures of T_{1Q} from the predictions of the Bayer equations can be expected at temperatures above $T_{m/5}$, T_m being the temperature at which orientational order disappears. Experimental aspects of relaxation time measurements were referred to by A.H. Brunetti (IMAF, Cordoba, Argentina) and there was some discussion of the usefulness of T_2^*, the spin-phase memory time, by S. Hacobian (University of Sydney) and M.A. Whitehead and coworker (McGill University).

Nuclear quadrupole resonance spectroscopists have long been worried about high-order nuclear electrical multipole contributions to their measured frequencies; S.L. Segel (Queen's University, Kingston) showed by careful frequency measurements on a number of nuclei such as $^{185,187}Re$ in NH_4ReO_4, ^{209}Bi in $BiCl_3$ and ^{93}Nb in $NbCl_5$ that there were no measurable hexadecapole contributions. The question as to whether this is generally true still remains. □

*The fifth international symposium on Nuclear Quadrupole Resonance Spectroscopy was held in Toulouse, France on 10-14 September, 1979. The co-chairmen were L. Guibé (Université de Paris) and G. Jugie (CNR, Toulouse).

J.A.S. Smith is Professor in the Department of Chemistry, Queen Elizabeth College, London.

Urban ecology

from Peter D. Moore

THERE are areas of ecology where the development of theoretical models has outpaced the accumulation of the field data necessary to test them. Often the observations which exist are not in the appropriate form, and models stand unchallenged until the required information is gathered. One conceptual model which has received much attention from various quarters in recent years is the idea of island biogeography and its applicability to fragmented habitats of all kinds. The original statements concerning the immigration, extinction and stabilisation of island biotas were tested experimentally by Simberloff and Wilson (*Ecology* **50**, 267; 1969), but since then the model has been used extensively in ecology, for example in the determination of the size and spacing of nature reserves (see May *Nature* **254**, 177; 1975). Although, theoretically the model can be used in any fragmented habitat where intervening areas are unsuitable for settlement, experimental or even detailed observation concerning its wider applicability are generally few. Some such applications are mountain tops (Brown *Am. Nat.* **105**, 467; 1971), fresh water habitats (Sepkoski & Rex *Syst Zool.* **23**, 165; 1974), oak trees and leaf-mining insects (Opler *Am. Scient.* **62**, 67; 1974) and cushion plants (Tepedino & Stanton *Oecologia* **25**, 243; 1976).

One type of habitat in which island biogeographic theory could be put to the test is the mosaic of wasteland produced by demolition in city centres. Here are sites which are available for colonisation by weeds from surrounding sources, invading across unfavourable intervening terrain. Often the age of such sites can be precisely established and it could be argued that a level of equilibrium between immigration and extinction should be established relatively rapidly. If this were so, then theoretical considerations would lead one to postulate that the number of species at a site should be a function of the site area and should be inversely related to the distance from the origins of immigrant flora.

Crowe (*J. Biogeog.* **6**, 169; 1979) has examined the potential of such sites in Chicago. He surveyed 26 vacant urban lots in the city, establishing a plant species list for each site in addition to the determination of lot area, age, distance to the nearest older lot and lot density in the area, among other parameters. A disadvantage of a single survey rather than a long term study of each site is that one cannot be sure that species equilibration has occurred; nothing is known of the actual pattern of immigration and extinction. Crowe demonstrates that the vast majority of species found in the younger lots have survived in older sites also, so the system has not reached a successional stage where competitive processes are leading to extinction. This is further confirmed by the fact that the species number in a lot is closely related to site age in the younger lots, but for older ones (greater than four years) there is little increase with time. This indicates, but does not fully prove, species equilibration.

The number of species in these older equilibrated lots is positively correlated with lot area and to the density of other lots in the vicinity (number of lots within 1 km). It is negatively related to the distance to the nearest lot. These two latter features are indices of isolation from potential sources of immigrant plants. Thus the conclusions reached are in keeping with the predictions of island biogeographic theory.

One further variable which requires consideration is the diversity of microhabitats available within any lot. Crowe has not attempted any such analysis, but this aspect of the island biogeographic model has been looked into by Simberloff (*Ecology* **57**, 629; 1976), who concluded that although habitat diversity is an additional complicating factor, if one can eliminate this variable experimentally there remains a residual relationship between number and island area.

Observational data, however, may not permit such a fine resolution of the influence of island area and habitat diversity, for the two are frequently themselves positively related. Thus, Juvik and Armstrong (*J. Biogeog.* **6**, 205; 1979) when examining the biogeography of the endemic honeycreepers (Drepanididae) of the Hawaiian archipelago, found a positive correlation between island area and species richness. But since larger islands are also more diverse in their habitats, generally having the higher mountains and more

Nutrient retention in tropical rainforests

from Robert M. May

IN the hour you might devote to reading this issue of *Nature*, more than 3,000 acres of tropical rainforest will be destroyed. According to the Food and Agriculture Organization of the United Nations, there were about 16 million km^2 of rainforest around the turn of the century, which by 1975 was reduced to 9.4 million km^2, representing a 40% reduction; a conservative estimate of the current loss rate is 27 million acres per annum, or 50 acres per minute. This mounting tragedy of the world's rainforests is an oft-told tale (two recent and powerful articles are by Lovejoy and Colinvaux in *Nature Conservancy News* **29**(4), 1979; see also *Nature* **257**, 737; 1975), and I intend here to dwell only on one narrow aspect of it.

Many lowland rainforests grow on very poor soils. These acid soils have low capacity for ion absorption, making them particularly susceptible to the leaching of all plant nutrients. Rainforest trees have responded to this by storing most of the nutrients of the forest in the trees themselves, and by evolving symbiotic associations with mycorrhizal and other fungi that recover and recycle those nutrients that make their way into the soil when a tree dies or when its parts are eaten and excreted by animals. Colinvaux extols these fungi, "Whose pervading presence contributes to that characteristic greenhouse smell of the forest. The smell of the fungi is the smell of life — the part of the system that circulates nutrients. When a rainforest is cleared, the smell is gone, and so are the nutrients that fungi and rootlets once conserved to make productive life possible."

Despite their importance, these ideas about direct cycling of nutrients in rainforests have only recently received direct experimental verification. In a most elegant study, Stark and Jordan (*Ecology* **59**, 434; 1978) added radioactive ^{45}Ca and ^{32}P to the surface of experimental plots in the Amazonian rainforest, near San Carlos on the Rio Negro in Venezuela. These radioactively labelled nutrients were added both in leaves and twigs placed on the forest floor, and as a direct chemical spray (simulating 'decomposed' litter) on the plots. The fraction of this radioactive material that leached through the root mat and humus layer was monitored for 6 months. In 9 of the 10 study sites, less than 0.1% — one part in a thousand — of the labelled nutrient leached past the root mat, and all leaching ceased after 1 to 2 months; in one of the 10 plots, slightly less than 1% of the radioactive material leached through. In addition, Stark and Jordan analysed root mat samples, showing directly that the radioisotopes were indeed taken up and translocated by living roots.

Noting that the history of the Amazon Basin and other tropical rainforests is filled with failure after failure to establish large-scale agriculture, tree plantations or pasture, Stark and Jordan are concerned to emphasise the message substantiated by their experiments: "The exploiters reason that an area that can support a luxurious forest should be able to support permanent agriculture. This study has demonstrated that this is not the case, because of the evolved and unique root mat which enables the undisturbed forest to survive." □

'ecozone patches', it proved impossible to extricate the pure area influence from that of habitat heterogeneity. Evidently this aspect of the island biogeographic model needs more attention in order to understand the area/richness relationship whether at the urban lot or the Hawaiian island level of organisation. □

Mapping the nuclear potential

from P.E. Hodgson

THE special characteristics of nuclear heavy-ion interactions enable the nuclear surface to be probed in detail, and this has recently been used by Nees and Guidry of Oak Ridge and Donangelo and Rasmussen of Berkeley (*Phys. Lett.* **85B**, 201; 1979) to map the deformed potential of the nucleus ^{160}Gd.

To do this, they analyse the inelastic scattering of ^{40}Ar by ^{160}Gd at energies comparable with that of the Coulomb barrier. This interaction excites several states in the ground-state band, and there is strong interference between the Coulomb and the nuclear forces. At these energies, the wavelengths of the ions are small, so that semi-classical theory can be used to understand the interaction. This shows that since both Coulomb and nuclear forces contribute to the excitation, both the charge and the matter distributions influence the interaction, and are thus both probed by it. At energies below the Coulomb barrier few non-elastic processes take place, and so the effects of the real and imaginary parts of the potential can easily be separated.

From the uncertainty principle we know that localisation in angle requires a large uncertainty in the momentum. If we consider the experimental situation as shown in Fig. 1, when scattering is restricted to backward angles, we find that the transfer of multiple rotational quanta implies a localisation in the orientation angle of the deformed rotor during the interaction, and hence a localisation in the part of the nuclear surface probed by the projectile. Classical phase space arguments show that each classical angular momentum I_f is associated with a range of initial orientations obtained by projecting two units of I_f on the angular axis, as shown in the figure. This spread in spin corresponds to a definite range of initial orientation angles, so that a particular spin state probes specific regions of the deformed nuclear surface.

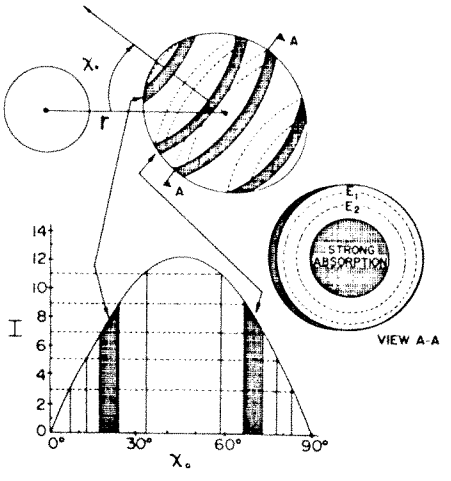

Fig. 1 Schematic illustration of the radial and angular localisation in heavy ion reactions. The more classical the system the more the surface interaction is localised in angle and in radial distance.

Similar arguments show that a large radial angular momentum implies localisation in the radial coordinate. Thus the initial width of the radial wave packet for ^{40}Ar on a heavy nucleus at the energies of these measurements is about 0.1 fm. The projectile spends most time in the region of the classical turning point, and so the interaction probes this region of the nuclear surface. As the incident energy increases the turning point moves inwards and with it the region being probed, until the particle is absorbed by the strong interaction in the nuclear interior.

These qualitative arguments are of course confirmed by numerical calculations that are fitted to the cross-sections for the inelastic scattering with the excitation of the low-lying states of the ground-state rotational band. A complex deformed Saxon-Woods potential was used, with fixed potential depths, and the radius and diffuseness parameters refer only to the localised region probed by the particular interaction.

From the results of these calculations the real part of the potential is constructed piece by piece, assuming axial and reflection symmetry. It is found that for each quadrant the classically allowed states (4^+ and 6^+) sample two regions while the classically forbidden ones (8^+ and 10^+) sample one broad region. The first three diagrams in the figure show the partial contributions of each state, and the final one the sum. It is notable that the contours overlap and join very smoothly, even though each comes from an independent analysis of a different part of the potential.

These potential contours can easily be parametrised in terms of an expansion in spherical harmonics to give a precise description in the usual form. They are closely related to the contours of the nuclear density distribution itself through a simple folding calculation with the nuclear interaction. Conversely, they may be used to check the accuracy of any particular form of the nuclear surface. This method of analysis of heavy ion interaction thus gives a very direct and clear description of what it means for a nucleus to be deformed, and should have many useful applications to studies of nuclear structure. □

Bird colours

from John R. Krebs

MOST biologists, if asked to hazard a guess about the possible significance of the brilliant plumage adornments of many bird species, would probably say that bright colours evolved in the context of ritualised display between rival males or as attractants to lure females. They would point to the fact that male birds are usually brighter than females, and exotic male plumage is especially highly developed in polygamous birds. Males generally compete for females, and this competition is more intense in species where one male can acquire a larger number of mates, so sexually selected colours are expected to be found in males, and especially in polygamous males. This was the line of argument put forward by Darwin, and although a number of alternatives have been proposed from time to time, the first serious attempt to examine Darwin's idea by means of a large scale comparative survey has recently been published by Baker and Parker (*Phil. Trans. R. Soc.*, **B287**, 63-120; 1979). As a result of their analysis, Baker and Parker reject the sexual selection hypothesis and replace it with what at first sight may seem a surprising idea: that bright colours have evolved in response to selection pressures exerted by predators.

More than 30 years ago, Cott published an extensive study showing that bright coloured birds are often distasteful (*Proc. Zool. Soc., Lond.* **116**, 371-524; 1946). His work started with an observation made while preparing museum skins in the Middle East. Cott noticed that hornets readily ate the flesh of cryptic birds such as the palm dove (*Streptopelia senegalensis*) and ignored the carcass of a conspicuous pied kingfisher (*Ceryle rudis*). This lead Cott to a study of the hornet's preferences for the flesh of 38 Middle Eastern birds ranging from the very cryptic wryneck (*Jynx torquata*) to the conspicuous white crowned black wheatear (*Oenanthex leucopyga*). These, and later tests with cats, and a survey of human gastronomic preferences, confirmed Cott's thesis that bright colours are often associated with unpalatability. The phenomenon of warning (aposematic) colouration is well known in insects, and Cott extended the idea to birds. Baker and Parker point out that distastefulness is not the only basis for aposematic colouration: if a prey item is hard to catch, bright colours may evolve as a signal of unprofitability. They suggest that this might be especially applicable to birds, which once they have seen a predator can manoeuvre fast enough to be almost certain of escape. Thus the bright colours of many birds might signal not only "I am distasteful" but also (or alternatively) "I am hard to catch" or "I have seen you". As with the conventional theory of aposematic colouration, Baker and Parker's thesis assumes that bright, as opposed to

Structure and function of eukaryotic genes

by Jonathan Wolfe

FIVE years ago few biologists would have predicted that the structural organisation of eukaryotic genes would be known in such great detail. However, although we now know the primary structure of several genes, the mechanisms by which their transcription is controlled remain unclear. Speakers at the fifteenth Harden conference* set out to bridge this gap between our knowledge of structure and its relation to function.

One system which we are on the way to understanding is the transcription and processing of yeast tRNA genes. The primary transcript of these genes is trimmed at both 5′ and 3′ ends and a short intervening sequence is removed to produce the mature tRNA. J. Abelson (University of California, San Diego) reported work in progress to purify the enzymes responsible for splicing out the intervening sequence, using as a substrate precursors purified from a temperature-sensitive mutant strain deficient in processing. A specific endonuclease and ligase have been separated, which are unusual in that they respectively create and rejoin a 3′ terminal phosphate and a 5′ hydroxy group. E. de Robertis (MRC Molecular Biology Laboratory, Cambridge) reminded us that tRNA precursors microinjected into *Xenopus* oocytes can be completely processed (*Nature* **278**, 137: 1979). That toad enzymes can correctly splice out the yeast tRNA intervening sequence is surprising since it has diverged markedly in sequence from that of *Xenopus*. B. Hall (University of Washington, Seattle) has taken advantage of the ability of *Xenopus* enzymes to process yeast tRNA correctly to probe the relationship between structure and function, by studying the transcription and processing of cloned mutant tRNAs in a *Xenopus* cell-free system. Twenty mutants selected by loss of nonsense suppressor activity, have been cloned and sequenced. Interestingly, all were found to lie within the 5′ and 3′ limits of the mature tRNA. One mutant, located in the intervening sequence, was not correctly transcribed and gave a primary transcript only 48 nucleotides long.

This type of 'surrogate' genetics can clearly provide information about the influence of primary structure on transcription and processing; however results obtained in heterologous systems should be interpreted cautiously. J. Beggs (Plant Breeding Institute, Cambridge) showed us that not all yeast and vertebrate systems are mutually compatible. She transformed yeast with a plasmid carrying the rabbit globin genes and flanking sequences. Globin transcripts were made: however the yeast did not splice out the first intervening sequence and transcription terminated within the second. This point was also made by C. Weissmann, in the Harden Lecture, who stressed the value of studying transcription and translation in a homologous system.

The yeast tRNA genes were not the sole topic of the meeting. C. Henschel (University of Zurich) reported results from M. Birnstiel's group who have now almost completely sequenced the sea urchin histone genes. They have found a Hogness box, the putative eukaryotic promoter, a short distance upstream of the H2A gene and have constructed a number of plasmids carrying small deletion mutants of this box or of the surrounding sequences. Sea urchin DNA supercoils, removed from the plasmid vector, were then tested (in *Xenopus* oocytes) for their ability to be transcribed and translated. Deletion of sequences between the Hogness box and the AUG codon of the H2A mRNA was found to have little effect on the amount of transcription. However, removal of the Hogness box greatly reduced transcription and led to variation in the point of initiation. What, at first sight, were contradictory results were related by R. Kamen (Imperial Cancer Research Fund, London) reporting work with a deletion mutant isolated by M. Bendig and W. Folk of the University of Michigan. He told us that deletion of an apparent Hogness box upsteam of the polyoma virus early region genes actually led to an increase in the rate of transcription initiated at a new site upstream of the deletion. However, the deletion extended into the 5′ end of the message and may have decreased the rate at which it was translated. One possible explanation of this result was therefore that the early region is under feedback control exercised by one of the protein products and the reduction in this inhibition may more than cancel out any possible decrease in transcription as a result of deletion of the promoter.

Surrogate genetics is clearly a powerful tool to investigate structure-function relationships in straightforward systems but it is of limited value when probing more complex situations. However, we were provided with one example of the rapid progress which molecular biologists can make when working with a complex system already well-characterised genetically. K. Nasmyth (University of Washington, Seattle) reported work in which he has confirmed the geneticists' 'cassette'model of yeast mating type switching. This model explains the 'switch' in mating type from α to a or *vice versa* which can occur in budding yeasts, by proposing that silent copies of the two mating type genes exist elsewhere in the genome (at loci HML$\alpha$and HMRa) and that they can reprogramme the locus at which the active mating type is expressed (MAT). Nasmyth has now shown common sequences at the MAT locus and at the loci HMLα and HMRa. Clones were selected for their ability to complement MATα^- yeast, which are unable to respond to mating type a hormones and it was then straightforward to clone all three loci. Heteroduplex mapping showed that although the clones had sequences in common they contained a or α-specific sequences and also sequences specific to each locus. □

Jonathan Wolfe is an Assistant Editor of Nature.

*Held at Wye College, Ashford, Kent UK on 16-21 September, 1979, and organised by Professor Peter Walker on behalf of the Biochemical Society.

dull, colours are needed to signal a warning, (although there is no evidence that predators learn faster to avoid bright colours). There is also a possible problem in explaining how the genes for warning colour spread in the first place, since each predator has to attack, and perhaps kill, a few individuals to learn its lesson.

Baker and Parker also suggest that some bird colours are used as 'flash colouration'. These are colours of otherwise cryptic animals which are exposed suddenly when a predator attacks. The predator is temporarily startled or confused, allowing its potential victim to escape. The bright red eye and black and white head of the night heron (*Nycticorax nycticorax*) might be such an example.

The evidence adduced by Baker and Parker for their hypothesis consists of a comparative survey of 516 species of western Palaearctic birds. For each species they coded conspicuousness on a scale of 0–5 for different regions of the body — crown, head, neck, back, belly and so on. They then carried out a stepwise multiple regression to look for correlations between conspicuousness of each body region and various ecological and life history variables such as diet, gregariousness, mating system, migration distance, and nesting behaviour. The analysis was done separately for adults, juveniles, males, females, summer and winter plumage. The authors admit that there are many inadequacies in their analysis, not least of which is deciding how conspicuous a bird is in its natural habitat.

I can mention only a few of the many

results produced by the analysis. As expected, males emerged as more conspicuous than females, and the dimorphism was more marked in polygamous than monogamous birds. These results seem to fit nicely with the classical sexual selection hypothesis, but according to Baker and Parker they do not. For example, within the polygamous species, only those in which the males display on open ground with a good view of approaching predators are bright coloured. This might be seen as supporting the idea that the bright plumage signals to the predator "I have seen you". Crypsis of females is generally related to their greater role in parental duties, and where males perform parental care they also tend to be cryptic, at least in the parts of the body most visible to predators. Because an incubating bird is more likely to be caught by surprise, it relies on crypsis rather than aposematic colours to escape predation.

A similar argument is used by Baker and Parker to account for the difference between diurnal and nocturnal birds. Diurnal birds are more conspicuous because they are usually alert to the approach of predators and are therefore unprofitable prey. Nocturnal birds rely on immobility and crypsis to avoid being eaten while they are asleep during the day, but they sometimes have flash colours which are revealed when the resting bird is disturbed. In this respect there is a parallel between birds and Lepidoptera, where diurnal forms are bright coloured and nocturnal species cryptic.

As with any comparative study of this sort, a major problem in the interpretation of Baker and Parker's results is to distinguish between cause and effect. Consider, for example, two polygamous species, the ruff (*Philomachus pugnax*) and wren (*Troglodytes troglodytes*). The former is strongly dimorphic and lives in open habitats where the conspicuous males display on communal ground. The wren is monomorphic and the cryptic males defend large territories in dense vegetation. According to Baker and Parker's thesis, male ruffs, as a result of living communally in open areas, are vigilant and therefore unprofitable to predators. Their bright plumage advertises their unprofitability. Male wrens in dense vegetation are easily surprised by a predator, and hence rely on furtive habits and crypsis to survive. But the interpretation can easily be turned the other way round. Suppose bright colours are always favoured by sexual selection, but that predation acts as a constraint to prevent sexually selected colours developing in some species. In the vigilant ruff the balance of these opposing selection pressures is in favour of sexual selection, while in the more vulnerable wren, predator selection has the overriding influence.

Baker and Parker restrict their analyses to overall differences between species in conspicuousness of particular body regions. Equally intriguing are remarkable convergences in the fine detail of plumage between unrelated species occupying similar ecological niches in different parts of the world. The African yellow throated longclaw (*Macronyx croceus*) and the North American meadowlark (*Sturnella magna*) constitute perhaps the most remarkable pair (Fig. 1), but there are many others. It is tempting to conclude that ecological selection pressures must influence the fine detail of plumage as well as overall conspicuousness, and a comparative survey like that of Baker and Parker could be a way of testing this conclusion. □

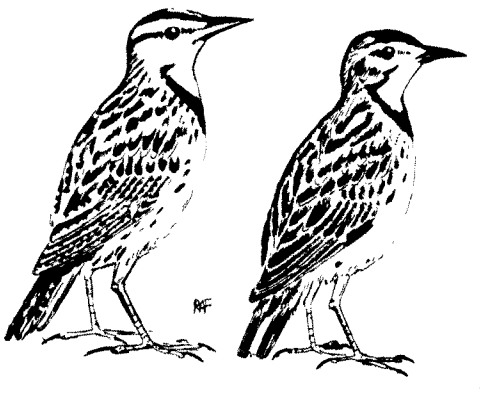

Fig. 1 Remarkable plumage convergence. The eastern meadowlark (left) is an American Icterid, while the yellow throated longclaw (right) is an African Motacillid, entirely unrelated.

John R. Krebs is a Lecturer in Zoology at the Edward Grey Institute of Field Ornithology, Oxford University, UK.

100 years ago

Several German newspapers strongly deprecate the undignified tone which seems to have reigned amongst the participators in the recent celebration at Pompeii. It appears that the majority of the visitors treated the whole matter as an excellent joke, and behaved very much as they would have done at a fair or at some other Neapolitan *fête*. Many of the archaeologists who had come long distances to be present at the celebration, left the dead city in disgust at the behaviour of the multitude, long before the proceedings were half over. One of the articles referred to expresses the hope that in the year 1979 the Neapolitans will have sufficiently improved in manners as well as gained in seriousness, to render a repetition of the digraceful scene impossible.

The London correspondent of the *Scotsman*, who is usually particularly well informed, states the Treasury has definitely decided not to ask Parliament for the cost of fitting up the new Natural History Museum at South Kensington and for the removal of the Natural History Department of the British Museum thereto till 1881. We are glad to be assured, however, that this statement should only be received as a rumour, and is not yet sufficiently authenticated. Let us trust that it will not be authenticated at all.

For the first time perhaps in the history of electric lighting two rival magneto-electric machines are illuminating the same hall. The Lontin and Siemens generators and lights are exhibited at about **120** yards from each other in the large hall of the Palais de l'Industri, at Paris. Each electrical machine is worked by steam, and consumes a certain amount of horsepower. The competition is too recent to offer yet any definite opinion on the respective merits of the apparatus confronting each other.

Telegrams from Murcia state that the city and celebrated *Muerta* were inundated by an immense waterspout which was formed in the sea at a distance from the coast on the night of October 14-15. Salt water was discovered at a distance of 45 kilometres from the sea. Another great atmospherical commotion was experienced three days afterwards. A night snowstorm enveloped the whole of Austria and Switzerland, and in Vienna the thickness of the snowfall was several inches. It is the first time since 1852 that snow has fallen so early in Vienna, but not the earliest time on record, as in 1760 it fell on October 12.

Mr. C. P. Edison, nephew of the great American inventor, has just died at Paris at the early age of twenty-four. He was his uncle's principal assistant in the production of the loud-speaking telephone, and was sent over to London by him to exhibit that instrument before the Prince of Wales, the Royal Society, &c. He had of late been engaged in applying his uncle's system of quadruplex telegraphy between Paris and Brussels.

The sanitary congress

This Congress continued its meetings at Croydon during last week, when several interesting addresses were given. Mr Douglas Galton, in his address last Thursday, spoke of that large class of conditions which are the direct result of the circumstances to which man is exposed in consequence of living in communities. All living beings are in a continual condition of change, which results in their throwing off from the body matters which poison earth, air, and water, unless space, time, and opportunity are afforded for the counteraction of these deleterious effects. He showed how thus resulted both epidemic and zymotic diseases, the presence or absence of which in any locality, and the degree of their virulence depend on the sanitary surroundings. Cholera and dysentery are principally connected with the condition of the water supply; while an epidemic prevails the questions whether a given population shall suffer or escape may almost be predicted from a chemical analysis of the drinking water. It is to the physiologist and the chemist that we must look for the causes from which these baneful effects arise, and what are the conditions which should be altered to prevent or remove them. The engineer steps in after these causes have been pointed out, and it is for him to design the methods of prevention or removal.

The seismicity, the horizontal and vertical ground displacements, and the geometry of active faults and fissures during the seismic and volcanic events of November 1978 in Southern Afar are consistent with an accentuation of the pre-existing topography of the Ghoubbet–Asal rift. The zone of sizeable permanent deformation is restricted to several hundred square kilometres. Elastic rebound models seem to explain the observations. The events occurred in the vicinity of the suggested location of the tip of a lithospheric crack which may have been responsible for the progressive opening of the western Gulf of Aden.

AN important seismic swarm started on 6 November 1978 in the subaerial part of the rift which links Ghoubbet al Kharab to Lake Asal in the Republic of Djibouti (Fig. 1). North-west–south-east trending faults and fissures were reactivated in the inner floor zone of the rift, over a width of 3–4 km and visible length of 15 km, and a new volcano, Ardoukoba, came into being between 7 and 14 November. The whole sequence of events took place in an intensely studied section of the world ridge system, one of the few such sections that stand above water. This paper describes the seismic and tectonic aspects of the events and summarises data, much of which have been previously published only in French. We attempt to relate the events to the structural environment of Southern Afar and to test their relevance to geodynamical models of the Red Sea–Gulf of Aden plate boundary. More detailed accounts of the various observations and measurements will be published elsewhere.

Seismicity

The seismic swarm started on 6 November 1978, and lasted for 2 months, compared with only 1 week for the volcanic eruption[1]. It was recorded by the seismological network of eight stations, most of which have been operating since 1972. Only three stations were operating at the beginning of the swarm, but all stations were back in use by 10 November. After a first increase in seismicity on 6 November when two earthquakes with $m_b > 4$ were recorded, the climax occurred on 7 and 8 November. On 7 November, 15 earthquakes had $m_b > 4$ and the major shock reached a m_b of 5.3. This event was located in the axial part of the Ghoubbet, not far from the coast (Fig. 1). On 8 November eight shocks with $m_b > 4$ and another one reaching $m_b = 5$ were recorded. From 7 to 10 November, the daily number of recorded events with $m_b > 0$ exceeded 2,000.

Most of the earthquakes that have been located so far occurred along the axial fault zone in the Ghoubbet; preliminary fault plane solutions suggest normal faulting, in agreement with observed submarine scarps. A composite fault plane solution from a series of earlier earthquakes gave a similar result (refs 2, 3 and Fig. 2). There was little seismic activity in the subaerial section of the rift where the volcanic eruption occurred. The main locus of seismicity migrated from west to east with time through the Ghoubbet straights to the Arta transform fault zone, following closely the active plate boundary whose detailed geometry is now reasonably well understood (refs 4–8 and Figs 1, 2). This eastward migration pattern is thus very similar to that observed in 1973 during a previous swarm in the Gulf of Tadjourah[9].

Geodetic measurements and levelling

In 1972–73, a network of 22 geodetic stations was emplaced around the active Asal–Ghoubbet area[10]. Immediately following the November 1978 events nine stations were remeasured (Fig. 1). These measurements demonstrate that between 1973 and 1978 a large amount (at least 1.6 m) of extension occurred perpendicular to the rift axis. To establish the characteristic dimensions ('wavelength') of the deformed zone, a second set of measurements of further geodetic points was made: the additional data[11,13], together with the levelling data to be discussed shortly, show that the zone of the deformation does not greatly exceed the width of the inner rift (of the order of 10 km). Tarantola, Ruegg and Lépine[14] have computed the principal directions of strain which are compatible with the observations. They find two narrow bands of contraction (strains of the order of 10^{-4}) that border the axial part of the rift (4 km) where north-east–south-west expansion dominates (with strains of the

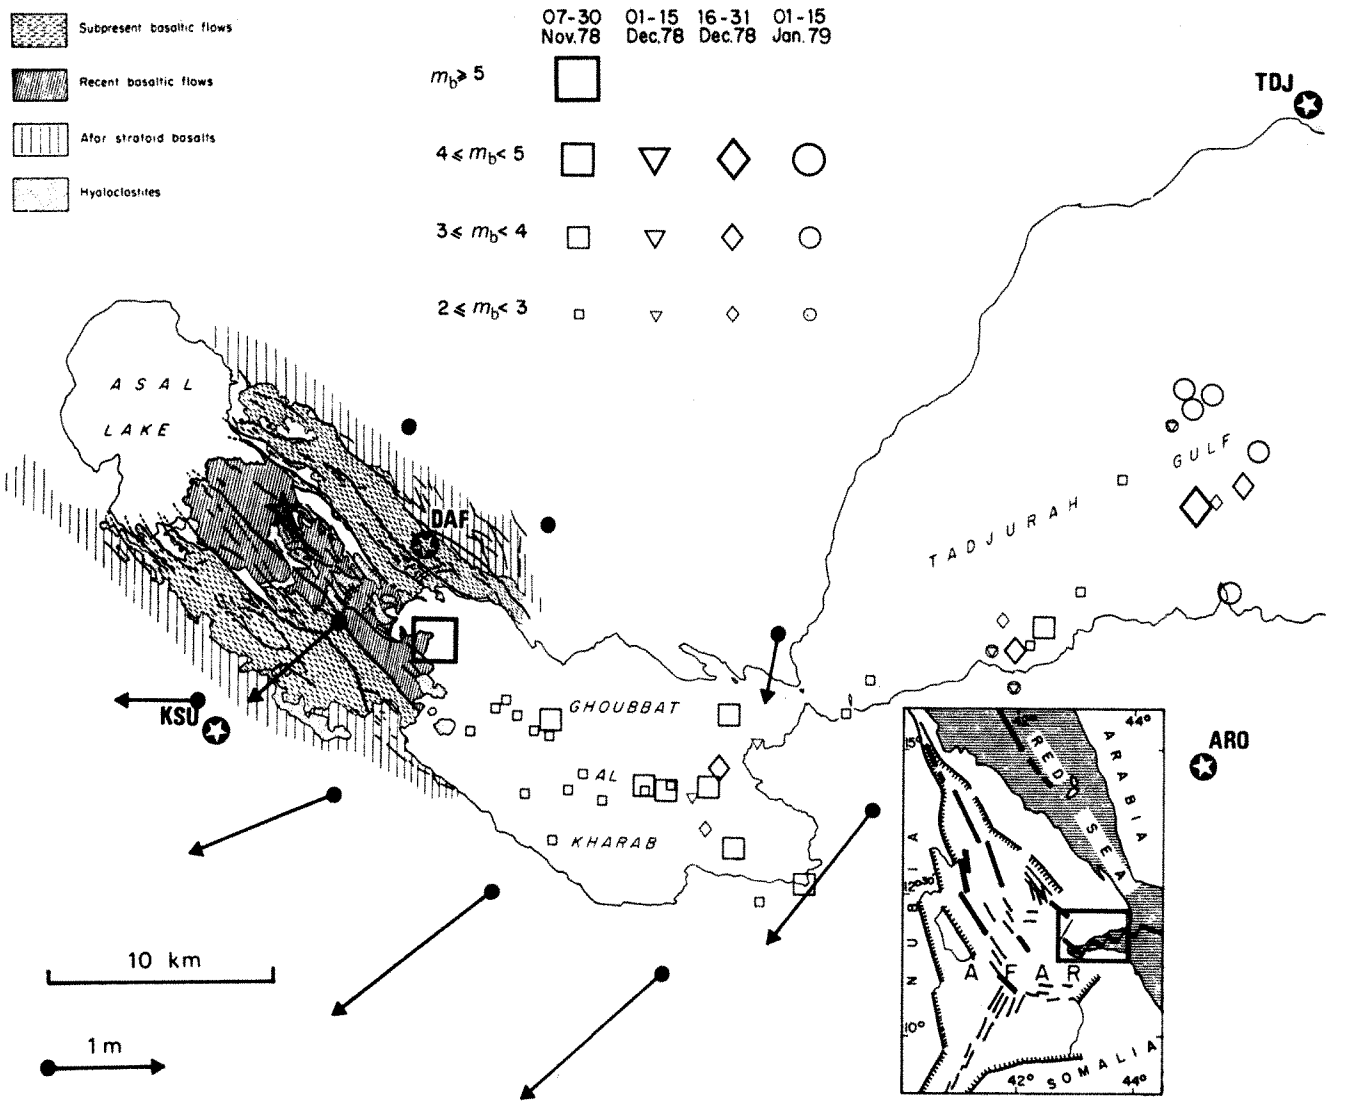

Fig. 1 Geological sketch of the Ghoubbet–Asal rift, evolution of seismicity from November 1978 to January 1979 (magnitude m_b and time of occurrence are given), and horizontal displacements (1973–78) measured at nine stations (the two northernmost stations are taken as reference, see refs 11, 12). Scales for displacements and for the geographical map are also shown. ☆, The November 1978 locus of volcanic activity; ⊛, some seismological stations. The general tectonic location is shown in the inset.

order of 2×10^{-4}). Computed strains seem to decrease with distance away from the Ghoubbet-Asal and become $<10^{-5}$ ~ 10 km from the axis.

In addition to the geodetic measurements, relevelling of a profile across the Ardoukoba rift, which had been measured first in 1972[10] reveals that, in the central part of the inner floor, a zone 2 km wide and 4 km long has subsided more than 70 cm (Figs 3*a* and 4*a*). The amount of subsidence decreases towards Lake Asal and the Ardoukoba volcano, and also, although perhaps less rapidly, towards the Ghoubbet. Subsidence is not symmetrical with respect to the geometric axis of the rift, as a smaller rift-in-rift structure to the north is active, with a subsidence of its own of approximately 30 cm (RR in Fig. 4*a*). The general effect of the deformation seen in Fig. 4 is to accentuate the preexisting topography. Both flanks of the inner rift are elevated up to 20 cm over a 1 km width; these zones of elevation correspond roughly to the bands for which the geodetic data indicate contraction. Four km away from the rift axis, both to the north and to the south of it, the gradients of vertical displacement become much smaller. Actually, complementary levelling, although not yet fully processed, shows a broad uplift, some 20 km in wavelength, over which the narrow elevated shoulders and deep subsided central part are superimposed[13].

Field tectonic observations

Detailed tectonic observations were made both on land and from air photographs at a scale of 1/10,000 (refs 15, 16). The recent structures, which seem to be related to the November events, generally follow older structures, with a north-west–south-east trend. Reactivation is clear in recent sediments (such as lacustrine limestones, diatomites and hyaloclastites) and in alluvial plains. Criteria such as freshness of the scarps, offsets in camel and road tracks or creeks have been used. However, it was not possible to find convincing criteria within the recent lava fields; such areas have therefore been left blank on Fig. 3*a*.

Structures fall into two categories: (1) normal faults, with a length from 100 m to several kilometres, and with a maximum throw of 70 cm (Fig. 5*a*); major faults are often associated with smaller antithetic faults. In alluvial zones, normal faults are sometimes paired to form graben structures (Fig. 5*b*) which may in some cases be the surface expression of deeper single faults. (2) Fissures of various types are also encountered: reopened fissures in which detrital filling has subsided (Fig. 5*c*), aligned collapse pits, which are interpreted as the surface expression of underlying fissures below the alluvial cover, and narrow and shallow small grabens that result from a coalescence of the

previous pits. Subaerial faults and fissures that have been reactivated during the events are very numerous and occur in a band of the inner rift which is 3–4 km wide and 8–10 km long (Fig. 3). Part of the deformation is concentrated in the small rift-in-rift structure which is located to the north-east of the inner floor (Figs 3 and 4*b*). The zone of present deformation is offset to the north with respect to the axis of symmetry of the overall rift topography. This suggests a northward migration or jump of the axial rift zone, consistent with the location of the present rift on the northern boundary of the main zone of Plio–Pleistocene lava accumulation and tectonics[7,8,17,18]. There is also a suggestion of *en échelon* rifts, within the inner floor between Ghoubbet and Asal, which is supported by the patterns of seismicity in the eastern part of the Ghoubbet[2,3,9]. This *en échelon* array is reminiscent (although the scale is quite different) of the *en échelon* fissure swarms which occur in the northern neovolcanic zone of Iceland[19,20]. The three smaller *en échelon* fissures that fed the volcanic eruption opened in the northwestern part of the rift, in a region where surface tectonics and seismicity are not otherwise intense.

The vertical throw of faults is largest in the central section of the rift and decreases both towards Lake Asal and towards the Ghoubbet. Transverse tectonic sections were mapped in detail in December 1978 and are shown in Fig. 4*b*. There is a general agreement between the tectonic profiles and the levelling measurements (Fig. 4*a*), particularly for the southern half of the rift: for instance, two major reactivated scarps are crossed between levelling points 33 and 34^{b} (Fig. 3*a*) with a 70 cm downdrop. Tectonic profile 3, which is not far from the levelling route in this neighbourhood, shows a cumulated throw of the same order of magnitude (1 m). However, along the same tectonic profile 3, a discrepancy appears between levelling points 35^{I} and 35^{II}: whereas the area is devoid of identifiable traces of brittle deformation (Fig. 3*a*), the levelling shows a 30 cm elevation difference (Fig. 4*a*). This may be because fresh brittle deformation is more difficult to observe in the lava surfaces which are found in this zone. Similar mismatches are found elsewhere, in a similar context. They may be related either to block tilting or to more distributed deformation of the surface cover in response to deep-seated faulting. Also, it is not certain that levelling and tectonic profiles reflect activity over the same time period.

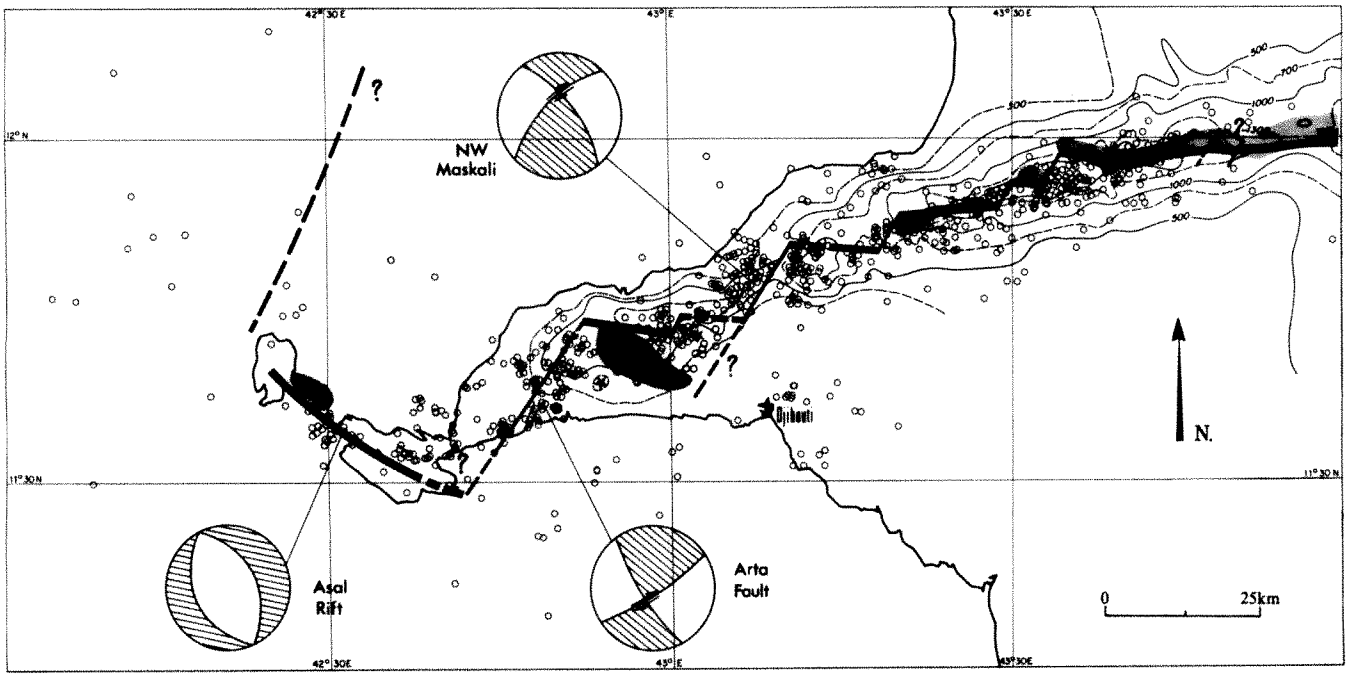
Episodic rifting along accreting plate boundaries

There are interesting similarities between the observations of seismicity and tectonic deformation presented here and those reported by Björnsson *et al.*[19,20] for a rifting episode on the plate boundary in the northern neovolcanic zone of Iceland. We have already pointed out the common en échelon arrangement of fault and fissure swarms, although in the Icelandic case only one such swarm has been reactivated since the current rifting episode started in 1975. A comparison between Figs 1 and 4 given here and Fig. 6 of the Björnsson *et al.* paper[20] reveals the striking similarity in horizontal and vertical ground movements in both cases. Note particularly the association of axial subsidence and extension with elevated side-shoulders showing evidence of contraction. This similarity between current rifting in Afar and Iceland (despite other differences) suggests that we are witnessing the fundamental mode of deformation at the axis of oceanic ridges. This adds to the already vast set of observations suggesting that there are few qualitative differences between tectonic processes in the axial zone of oceanic ridges and those which can easily be observed directly in Afar and Iceland[21–24].

One should not misinterpret[1] the relationship that may exist between a single event and long term motions occurring at a plate boundary. It is the superimposition of numerous discrete events of this kind both in space and time along the plate boundary that are integrated to give the slow (1 cm yr^{-1}) motion of the plates[17,18,25–27]. Thus, the large extension of ~2 m that occurred between 1973 and 1978 in the Ghoubbet–Asal rift zone does not reflect the increase in distance between the Arabian and African plates in the same time interval.

Elastic rebound and faulting

Perhaps one of the most important results to emerge from the geodetic measurements is that deformation occurred in a coherent pattern, in an area that probably does not exceed a few tens of kilometres in width. The first model which comes to mind to account for these observed deformations is the elastic



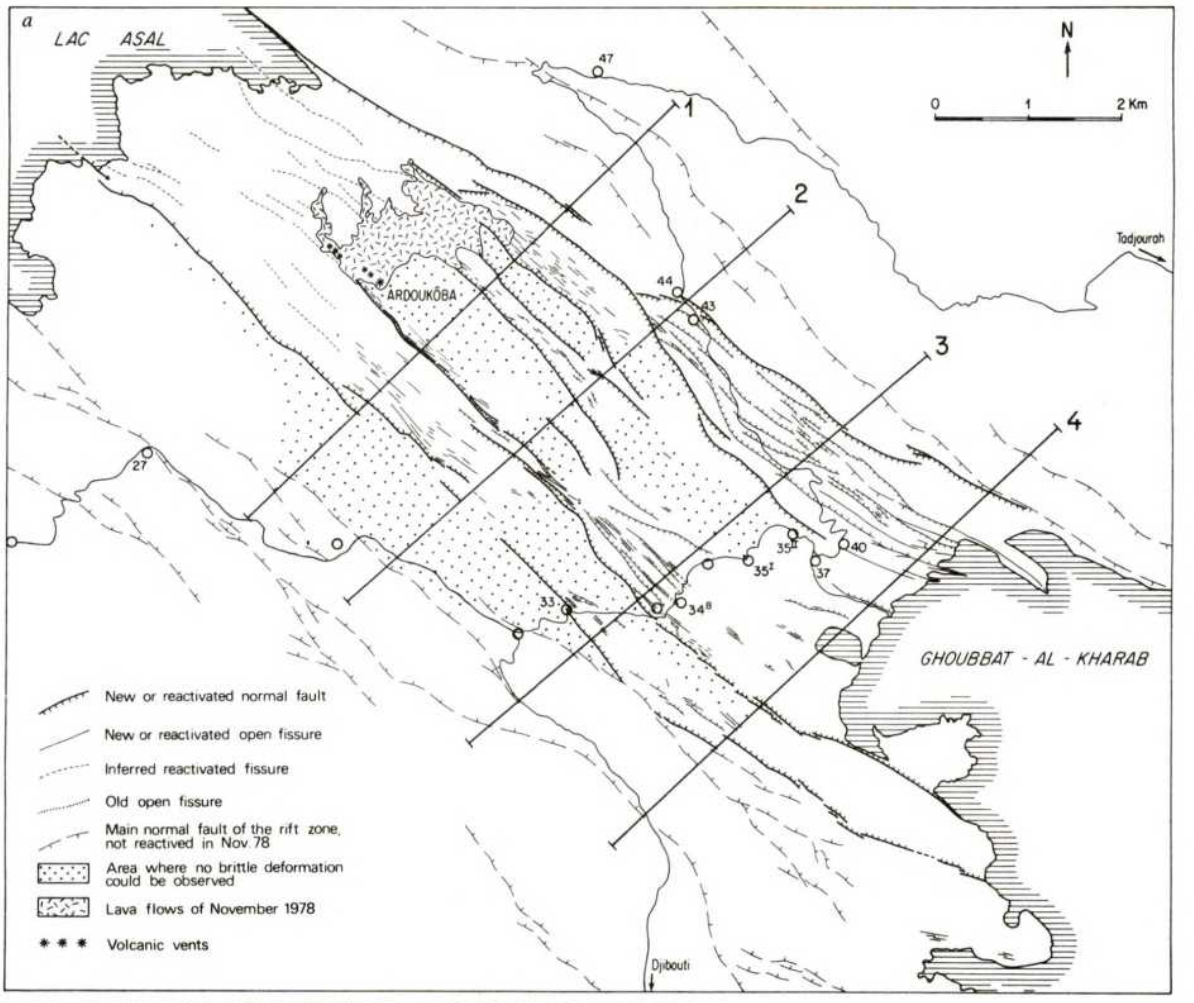


Fig. 2 Detailed bathymetry, earthquakes (○) and composite focal mechanisms for the period 1972–77 (see refs 2, 3, 17). ☆, Submarine volcanoes. Negative axial magnetic anomalies from Fig. 6 are shaded (after ref. 17).

~~R507~~ R408

rebound model, introduced by Reid[28] for the study of the 1906 San Fransisco earthquake. The model must, of course, be adapted to the case of normal faulting. The global forces that are responsible for plate motions presumably put the whole of Afar under extension with the principal direction being roughly north-east–south-west and energy is stored as elastic deformation builds up. During the seismic events, this energy is released and a zone of tens of kilometres in width is permanently deformed. Mansinha and Smylie[29] give analytical expressions which enable one to compute the displacement fields due to slip on inclined, finite, dip-slip (and strike-slip) faults, which are modelled as Volterra dislocations. Savage and Hastie applied this formula to the case of a fault with both dip- and strike-slip (refs 30, 31). Their results suggest that both vertical and horizontal ground displacements shown in Figs 1 and 3 can reasonably be accounted for by dip-slip faulting (with a throw of more than 1.5 m) on two normal faults with opposite dips, corresponding roughly to the walls of the inner rift. This would especially agree with the observation of both elevated and contracted lateral bands (see, for instance, Fig. 8 of ref. 30). Of course, faulting did not necessarily occur instantaneously on both faults, and these two faults give an integrated picture of the action of many smaller faults during the November 1978 swarm. This deformation is to be added to the deformation that may have taken place in the previous years. Alternatively, the horizontal displacement data can be accounted for by a 3-m opening of two finite vertical fissures, trending north-west–south-east, close to the axis of the inner rift, one in Ardoukoba rift and the second below the Ghoubbet waters where most of the seismicity occurred[14].

We should note at this point that much of the permanent outward tilt of blocks on both sides of the rift may be due to the integration of such deformation episodes and not only to isostatic response[21]. This may help to explain observations of rather large tilts on oceanic ridges.

1978 Events and geodynamical models of Afar

Although various plate tectonic analyses of the Red Sea–Afar-Gulf of Aden area have been published[18,25] it is still apparently very difficult to define plate boundaries within Afar[7,8,17]. On the basis of a new detailed aeromagnetic survey of the Republic of Djibouti (Fig. 6 and refs 7, 8), one of us (V.C.) has proposed that the western termination of the Gulf of Aden and the Gulf of Tadjourah were opened by the westward propagation of a crack in the lithosphere. Magnetic data and rock ages on land are interpreted to show that the crack has been propagating fairly regularly at ~3 cm yr^{-1}. It is suggested that the tip of the crack is now lying in the vicinity of Lake Asal. Bathymetric data and seismicity recorded over the period 1972–78 (refs 2, 3, 9) agree with this suggestion (Fig. 2): in particular, Lake Asal is seen to mark the westward termination of the narrow, well defined band of seismicity which corresponds to the active plate boundary.

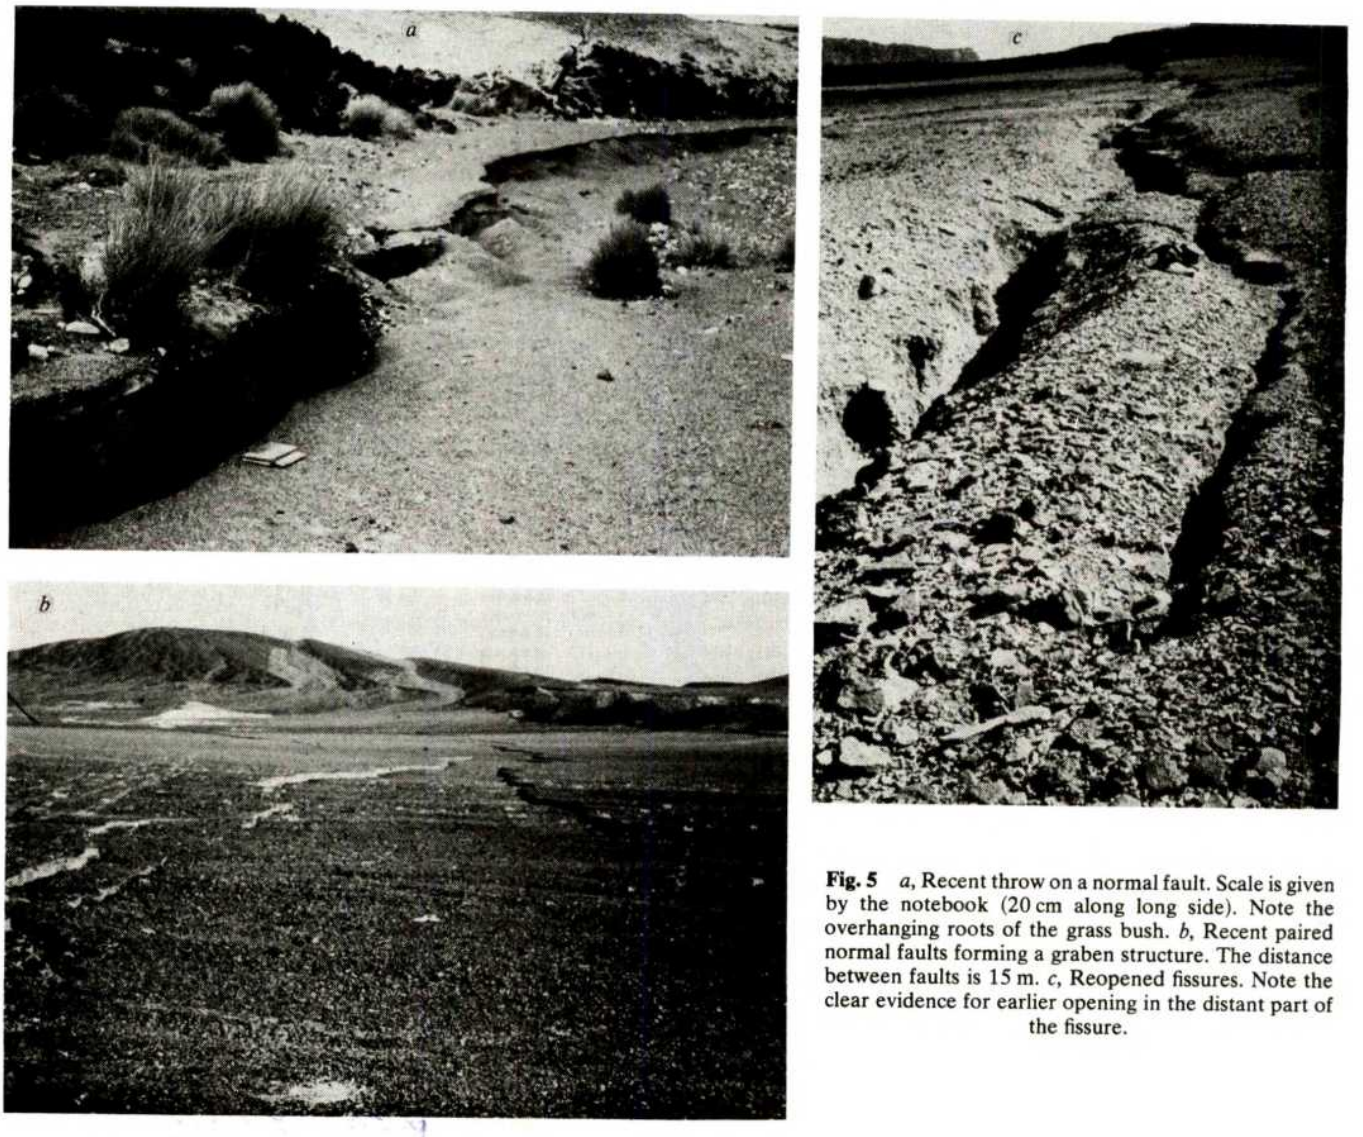

Fig. 5 *a*, Recent throw on a normal fault. Scale is given by the notebook (20 cm along long side). Note the overhanging roots of the grass bush. *b*, Recent paired normal faults forming a graben structure. The distance between faults is 15 m. *c*, Reopened fissures. Note the clear evidence for earlier opening in the distant part of the fissure.

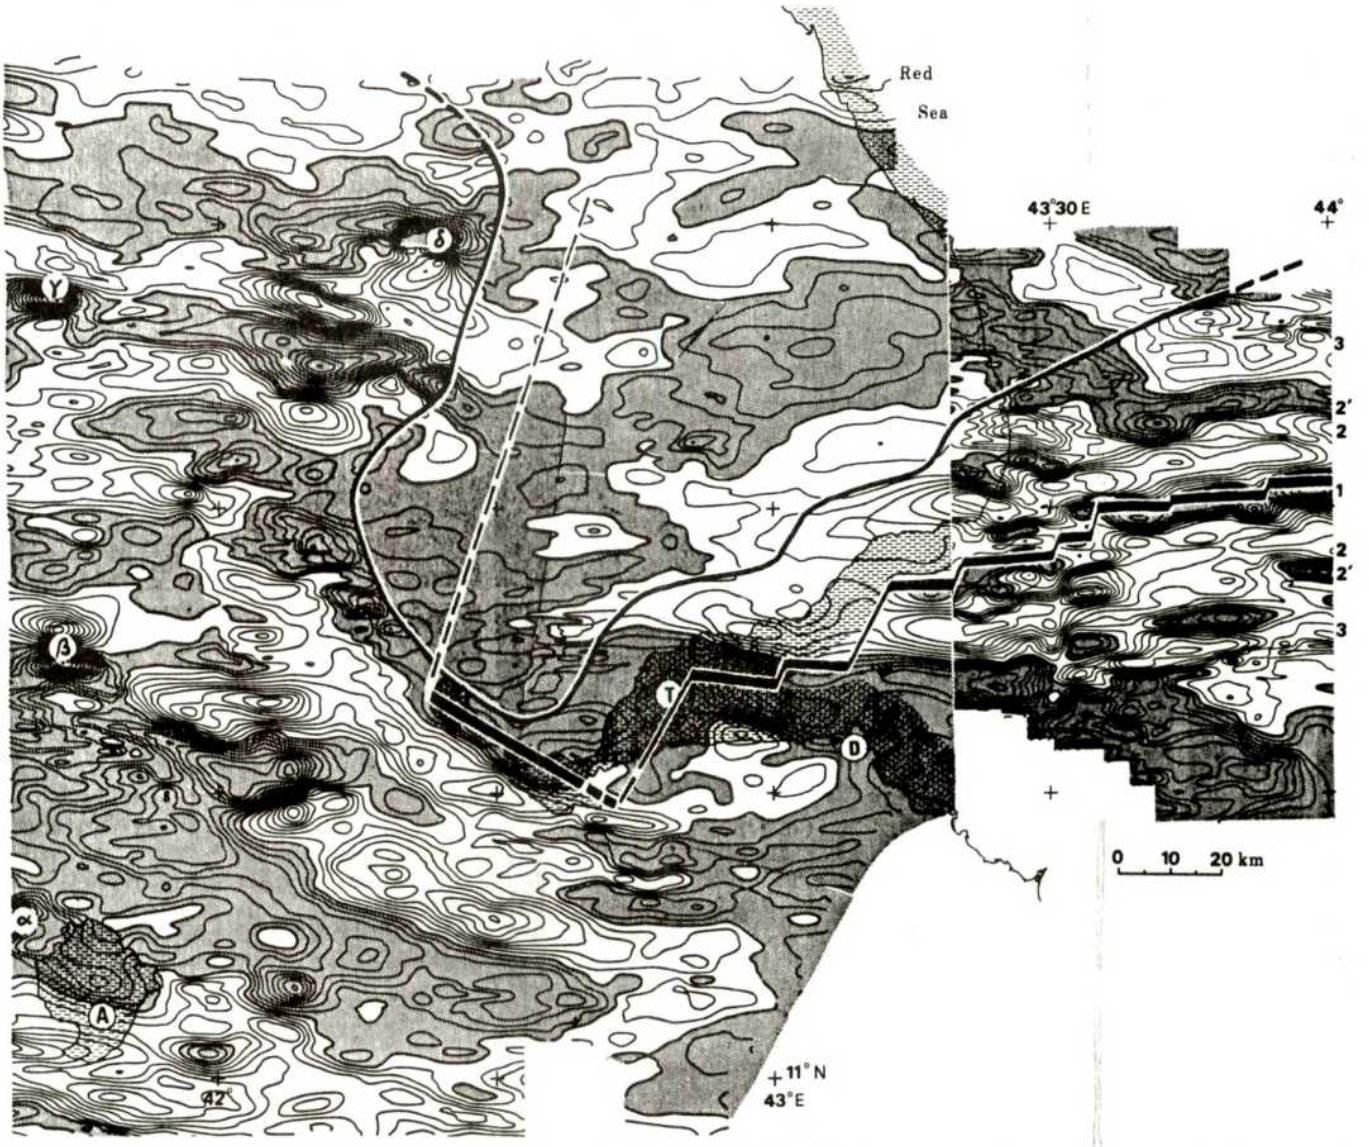

Fig. 6 Aeromagnetic anomaly map of the Republic of Djibouti (after refs 7, 8, 17). The plate boundary is indicated as a sequence of thick (ridge) and thin (transform fault) segments; the Mak'arrasou "transform fault" (refs 4–6) is shown as a dashed line. Also shown as a sinuous line is the boundary between zones of oceanic and more subdued magnetic styles (see ref. 17).

West of Lake Asal, seismicity seems to be more sparse and diffuse.

Thus, the November 1978 events would have started close to the suggested location of the crack tip. It is interesting then that the migration of seismicity away from the crack tip during the swarm and the distribution of the amplitudes of deformation (which are larger in the Ghoubbet than in the immediate surroundings of the volcanic centre) are compatible with the idea that to the west of the crack tip lies a locked area which is more resistant to deformation than the zone along which the plate boundary has already penetrated.

We thank Peter Molnar for critically reading the manuscript. The Programme Interdisciplinaire de Recherches pour la Surveillance des Eruptions Volcaniques (PIRPSEV) and Institut national d'Astronomie et de Géophysique (INAG) provided financial and logistic support for fieldwork. Authors are listed in alphabetical order.

The eruption of Soufrière volcano, St Vincent April–June 1979

J. B. Shepherd*, W. P. Aspinall*, K. C. Rowley*, J. Pereira†, H. Sigurdsson‡, R. S. Fiske§ & J. F. Tomblin*

The Soufrière volcano in St Vincent began to erupt on 13 April 1979 after 10 months of mild premonitory activity. A series of strong vertical explosions between 13 and 26 April generated ash falls, pyroclastic flows and mudflows. From about 3 May onwards basaltic–andesite lava has been accumulating in the summit crater.

ST VINCENT is in the south of the chain of volcanic islands which comprise the Lesser Antilles Island Arc (Fig. 1). The island is 30 km long and the Soufrière volcano constitutes the northernmost third of the island with a diameter of 11 km at sea level. It is a strato-volcano 1,220 m high with an open summit crater 1.6 km in diameter located in the southern part of a 2-km wide somma crater. The summit crater has been occupied by a 1-km wide crater lake throughout most of its history[1–4]. Explosive eruptions occurred in 1718, 1812 and 1902–03; the 1902–03 eruption was preceded by a 14-month period of felt earthquakes, and generated ashfalls, mudflows and pyroclastic flows climaxing on the afternoon of 7 May, 1902, when pyroclastic flows swept down valleys leading to the east and west coasts killing, 1,565 people. The eruption continued intermittently until March 1903 by which time the total volume of uncompacted pyroclastic ejecta is estimated to have been 0.42 km^3 (ref. 5).

In contrast, the eruption of 1971–72[4,6] was aseismic and non-explosive. Between October 1971 and March 1972, 80×10^6 m^3 of basaltic andesite lava were quietly extruded into the summit crater causing the evaporation of 55×10^6 m^3 of water out of an original lake volume of 75×10^6 m^3. During the later part of this eruption seismic activity at the volcano was monitored by three high-gain, short-period seismographs all within 4 km of the crater but no seismic events were recorded other than small surficial events associated with the growth of the lava mass. The number of these events had declined almost to zero by the time that the extrusion of lava ended in March 1972 and they had ceased entirely when the seismograph stations were withdrawn in August 1972.

Activity premonitory to the 1979 eruption

Since August 1972, the nearest seismograph station to the volcano which was in continuous operation was station SVT 19 km to the south. The temperature at the southern edge of the crater lake, which had reached a peak of 81.5 °C in November 1971 was measured twice per month and found to decline steadily until January 1975 when it stabilised between 23 and 26 °C which is 1–4 °C above ambient conditions. The crater lake was inspected about every 3 months. After March 1972, the crater lake and island showed little change other than a gradual erosion of loose material from the island. Fumarolic activity was at first widespread over the island but by 1975 activity was concentrated in a depression of diameter ~20 m in the centre of the island. A bathymetric survey of the crater lake was made in February 1973[7] and surface temperature surveys were made in March 1974 and December 1978. In March 1974, a large yellow stain became visible on the surface of the lake in the south-eastern corner. At this time the temperature around the edge of the lake ranged from 30 to 33 °C, rising to 47 °C close to the lava island. The yellow stain persisted until the start of the 1979 eruption. A similar stain was reported by Senn[8] in 1946 after a series of local earthquakes had been felt in northern St Vincent.

The first signs of abnormal activity which might be related to the present eruption were observed between August and November 1976 when a phreatic eruption of the Soufrière volcano in Guadeloupe 310 km to the north was in progress. Between 11 August and 21 October the water temperature at the southern edge of the lake rose from 23 to 30.5 °C. No other signs of abnormal activity were observed and by 19 January 1977 the temperature had decreased to 25 °C. In February 1978 the temperature began to rise slowly and irregularly, reaching a peak of 31 °C on 21 August 1978. On 2 June 1978 a short-period seismograph linked by radio telemetry to the University of the West Indies in Trinidad was established at Belmont, 9 km south-west of the crater (SVB in Fig. 2) and on 12 June this station began to record events which were tentatively identified as B-type volcanic earthquakes[9]. The events occurred in bursts of up to 20 and their frequency increased throughout June and July reaching a peak on 30 July when 40 events were recognised. Because of the simultaneous rise in lake temperature and increase in seismic activity, the local authorities were advised on 24 August that an abnormal situation might be developing at the volcano. Tilt monitoring stations of the optical tiltmetry type which were first established on the eastern flanks of the volcano in February 1977 at distances of 3 km and 6 km from the crater were re-occupied on 7 March 1978 and again on 17 September 1978. The results showed apparent tilts of order 3–5 μrad, consistent with inflation of the volcano, between March 1977 and September 1978. These were the first optical tiltmetry measurements to be made in St Vincent and the standard error of a single set of measurements was of the order of 4 μrad. The tilt results alone could not therefore be taken as conclusive evidence that the volcano was inflating. Inspection of the crater lake and island showed no significant change but a second telemetered seismograph station established 3 km south-west of the crater on 19 September (SVV on Fig. 2) confirmed that the seismic events originated close to the volcano. From 19 September 1978 to 12 April 1979 these two stations continued to detect B-type events at rates of up to 50 per day but the rate of occurrence showed no tendency to increase or decrease with time. No earthquakes were reported to be felt and only a few of the stronger events were detected by station SVT. During the same period the surface temperature of the lake was measured weekly and fluctuated between 27 and 30 °C up to 11 April 1979 when it was 28 °C. On 24 December 1978 the surface temperature of the lake was measured on one complete circuit of the lake around the island and was found to be a uniform 30 °C except for a hot spot close to the eastern edge of the island where it was 47 °C.

At 07.13 UTC on 12 April a large B-type earthquake was recorded by SVV and SVB and at about the same time continuous tremor became recognisable above the back ground microseismic level. For the following 12 h B-type events continued at

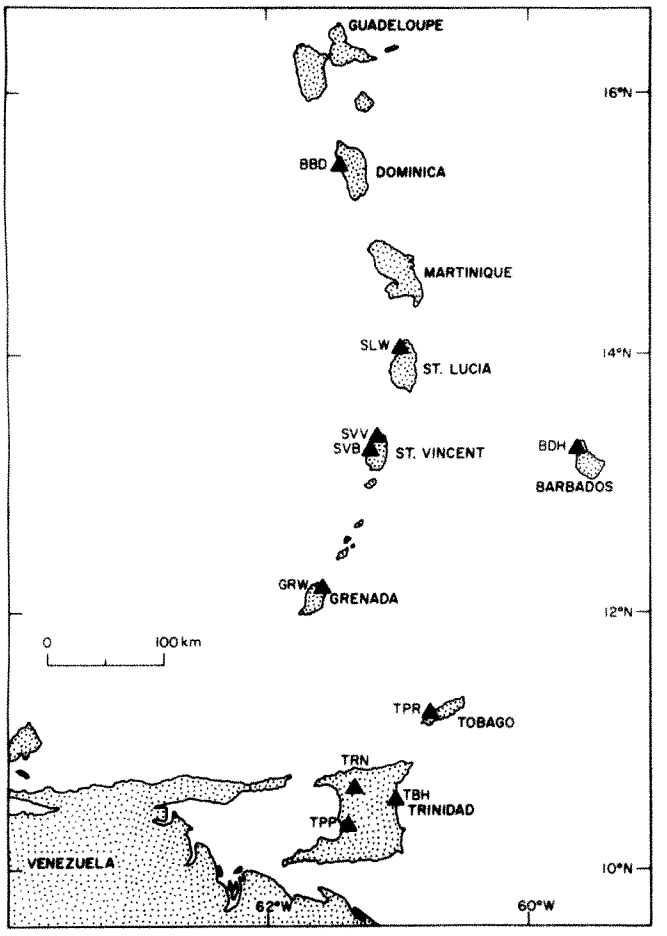

Fig. 1 Regional position of St Vincent in the Eastern Caribbean. The seismograph stations (▲) shown are linked by radio to Trinidad; many other instruments exist in the region.

a mean rate of about one per hour until 19.54 UTC when their frequency began to increase. Between 19.54 and 02.04 UTC on 13 April, 38 events were recorded with generally increasing amplitude and the level of continuous tremor increased steadily. Between 02.04 and 04.30 UTC, 70 events were recorded before continuous tremor saturated both instruments and individual events could no longer be distinguished. At 03.30 UTC (11.30 p.m. on 12 April local time) the government of St Vincent was warned that a highly abnormal situation existed at the volcano, but local residents 6 km east of the crater reported that they had neither seen nor felt anything unusual up to this time. At about 08.00 UTC loud rumbles were heard both east and west of the volcano and shortly afterwards fine ash began to fall at distances of up to 5 km south-east and south-west of the crater. When dawn broke at about 09.30 UTC the volcano was seen to be erupting a column of steam and ash and evacuation of the areas north of the Rabacca and Wallibou rivers (Fig. 2) began immediately. The evacuation was completed smoothly by 20.00 UTC and within the next 24 h about 15,000 people were evacuated from this area.

Early stages of the eruption

Figure 3 summarises the eruptive and associated activity from 12 April to 17 June. From 09.30 to 15.00 UTC on 13 April no one person kept the volcano under continuous observation but from numerous reports we deduce that there was continuous strong steam emission from the crater for the whole of this period, punctuated by powerful vertical explosions which projected ash-laden clouds to heights in excess of 8 km. After the initial outburst further distinct explosive phases were observed at about 10.15 and 15.15 UTC. At 11.20 UTC the eruption column was observed from a commercial aircraft to be at a height of 10 km, 150 km, south-east of the volcano. The column height was then ~8 km and an anvil-shaped cloud extended 80 km to the east. The column was again seen at 12.50 UTC from the same distance and appeared to be unchanged. At 15.00 UTC two of us saw the column from an aircraft approaching St Vincent from the south. When first observed the eruption column and cloud fitted the earlier description, but at 15.15 UTC a dark, cauliflower-shaped cloud was projected upwards above the column and drifted off to the east. At 16.00 UTC we flew low over the eastern and western flanks of the volcano in a light aeroplane and landed briefly at the Rabacca River 7 km south-east of the crater. At this location, fine light-grey volcanic ash was falling lightly but steadily and had formed a layer ~3 mm thick. The aerial inspection showed that a thin layer of ash had been deposited to distances of at least 10 km from the crater. We saw no evidence of pyroclastic flow deposits on the lower flanks, but the uppermost third of the volcano was obscured by falling ash.

After 16.00 UTC the dense steam-and-ash column dispersed although steam continued to pour from the crater. At 19.30 UTC we established an observation post at Belmont (SVB on Fig. 2) and since then the volcano has been kept under continuous visual surveillance. Explosive activity was renewed at 20.05 UTC and further explosive phases began at 21.08 UTC and 23.50 UTC on 13 April and at 01.08, 07.06 and 15.50 UTC on 14 April. The explosive phases varied in duration and intensity but were all broadly similar. Each began with rumbles audible from Belmont followed within 1 min by the emission of a white cloud which rose and expanded rapidly. One to two minutes later the clud became much darker and assumed a distinctive cauliflower shape, rising and expanding rapidly and mushrooming outwards at a height of about 4 km above the crater rim. Ultimate heights of the eruption columns could not easily be estimated from the ground but the eruption clouds generated by the explosions from 21.08 UTC on 13 April onwards were photographed from a NOAA Earth satellite and maximum column heights have been estimated by comparing the temperature at the top of the cloud with standard atmospheric temperatures. By this method the columns from the explosions at 21.08 UTC on 13 April and at 01.08 and 15.50 UTC on 14 April have been estimated to reach heights of 17–18 km. The other eruption columns did not penetrate the meteorological cloud layer and no similar estimates of their heights could be made. The lower part of each cloud drifted to the west in the prevailing trade winds while the upper part drifted to the east in the upper-level westerlies. Transport of the ash-plume resulted in ash fall on Barbados, 180 km to the east on the afternoons of 13 and 14 April. On the western flanks of the volcano air-fall from this series of explosions consisted mainly of fine, light-grey, crystal-rich ash but fresh scoria up to 70 mm in diameter fell on Georgetown, 9 km south-east of the crater. The maximum air-fall thickness at the eastern flank of the volcano 7 km from the crater was 40 mm. All explosive activity originated in the western part of the crater at the approximate location of the island formed in 1971–72.

Pyroclastic flows

During the explosive phase beginning at 21.08 UTC on 13 April we observed a pyroclastic flow which descended the upper part of the Wallibou river valley to the south of the crater. At the Rabacca river crossing 7 km south-east of the crater it was reported that a pyroclastic flow descended part of the way down the Rabacca river valley during the same explosive phase. Further signs that pyroclastic flows were being generated during the phase beginning at 01.08 UTC occurred on 14 April when incandescent material was projected over the crater rim and cascaded down the southern and western flanks. A low-level aerial reconnaissance at dawn (about 10.00 UTC) on 14 April showed a fresh pyroclastic flow deposit in the upper part of the Rabacca valley. The largest pyroclastic flow that we observed descended the 3-km long Larikai valley to the west of the crater at 16.00 UTC on 14 April and continued out to sea for at least 10 km. When inspected on site, 28 h after emplacement, the

deposit at the mouth of the Larikai was 1.5 m thick, ~250 m wide and contained scoria blocks up to 600 mm in diameter in a matrix of ash and lapilli. A pyroclastic flow rich in blocks of scroria and carrying trunks and limbs of trees descended the adjacent Roseau valley at about the same time, to within 100 m of the sea.

Subsequent explosive activity

From 17.00 UTC on 14 April to 20.57 UTC on 17 April the volcano was in a state of mildly explosive activity emitting mainly steam but with occasional cauliflower-shaped, ash-laden clouds rising to heights of 1–2 km above the crater rim. On 17 April the lower tilt-meter sites on the eastern flanks were reoccupied and showed tilts of ~4–6 μrad indicating deflation of the volcano since September 1978. At 20.57 UTC on the same day another explosive phase similar to the previous ones began. Pyroclastic flows were again observed to descend the Larikai, Roseau and Wallibou valleys to the west of the crater but none reached the sea. The height of the eruption column was measured from a NASA aircraft near St Vincent and was estimated to be 18.7 km. Ash fall at Belmont was coarser than in previous explosions. Initially it consisted of lapilli up to 10 mm in diameter grading down to fine ash over a period of ~50 min. Coarse scoria again fell on the eastern flanks as far as Georgetown. All these explosions were accompanied by severe electrical storms in which lightning discharges both within the eruption cloud and from cloud to ground occurred at a rate of more than 1 per s. Lightning strikes were observed at distances of at least 9 km from the crater and caused damage to trees 6 km east of the crater. A striking feature observed during the explosion of 17 April was the development of smooth, funnel-shaped bands of condensation around the eruption column immediately below the cauliflower-shaped eruption cloud.

After the 17 April explosion the volcano returned to a state of intermittent, mild explosive activity, generally declining in intensity but punctuated by two further explosive phases beginning at 10.37 UTC on 22 April and 03.53 UTC on 26 April. During the 22 April explosion a small pyroclastic flow descended the Larikai valley. A few minutes later a dilute pyroclastic flow was formed from ash that fell from a billowing cloud of

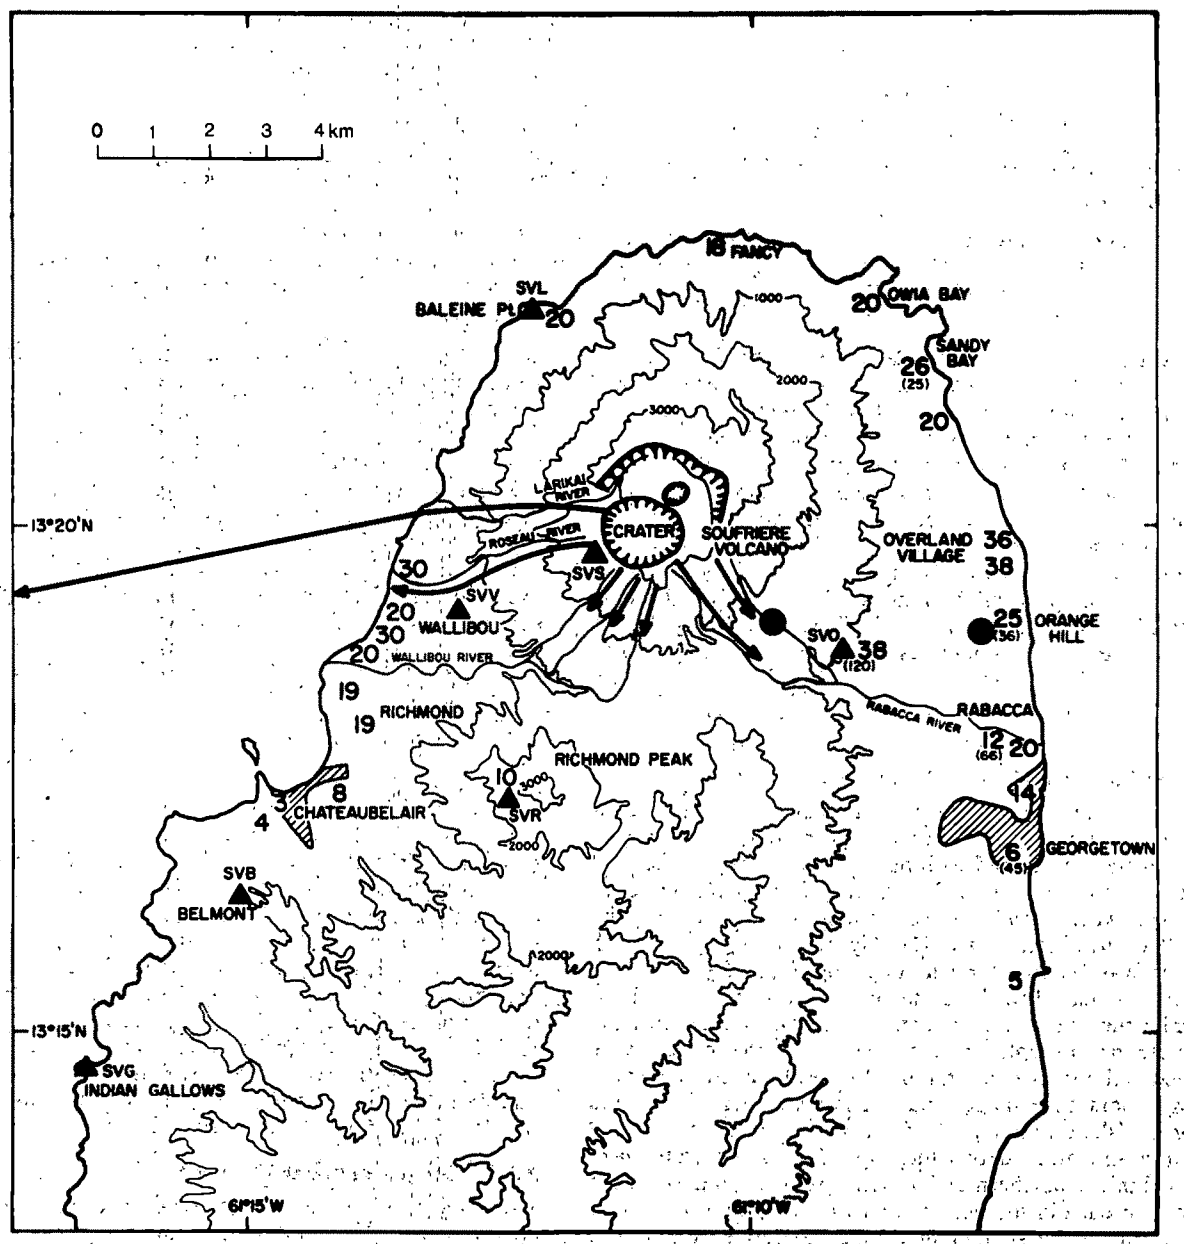

Fig. 2 The northern part of St Vincent island showing the location of the Soufrière volcano, major streams, general topography and two principal towns. The courses of pyroclastic flows known to have taken place in the 1979 eruption are shown as arrows and measurements of ash thicknesses (mm) are given as large numerals. The positions of tiltmeter (●) and seismograph station (▲) are also indicated. Figures in parentheses are maximum bomb dimensions (mm).

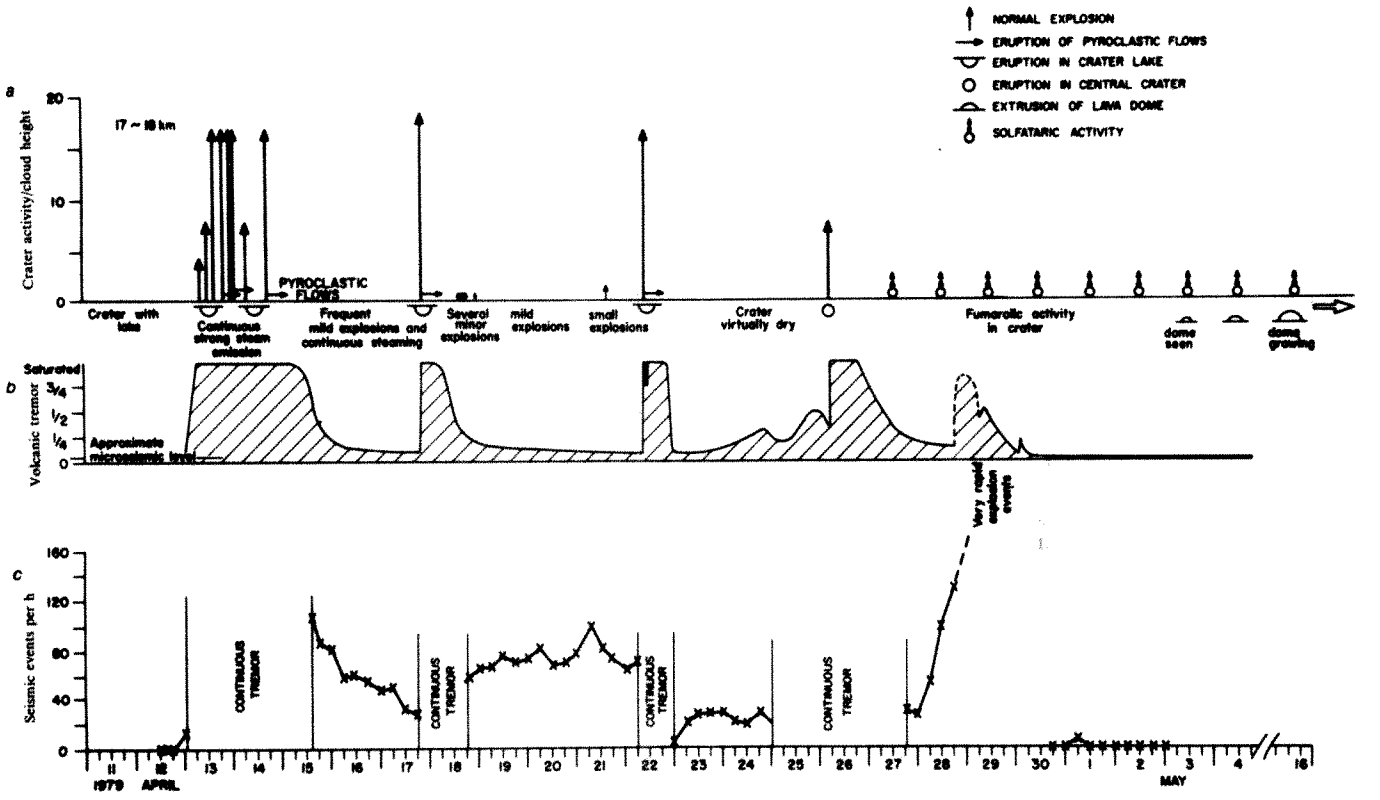

Fig. 3 Chronological summary of the major eruptive events and seismic behaviour of the Soufrière Volcano for the period 11 April–16 May 1979. *a*, The form of activity at the crater; *b*, the approximate level of continuous volcanic tremor; and *c*, the number per hour of discrete seismic events (explosion and B-type earthquakes), when these could be discerned from the continuous tremor.

airborne tephra and this flow, dark grey to black in colour, crossed the coast and spread as far south as Chateaubelair Bay. After this explosion the main axis of ash fall extended east from the crater with maximum total thicknesses along the east coast of the order of 40 mm at Overland Village, thinning to 10 mm at 5 km to the north and south. These figures are lower limits since each ash fall was rapidly eroded by wind and rain soon after deposition. Similarly the pyroclastic flow deposits in river valleys were rapidly reworked by streams and covered by mudflows which began to form on the night of 14–15 April. The final explosion of the series began at 03.53 UTC on 26 April. The height of the eruption column was measured from HMS Gurkha 15 km to the west and was estimated to be 8 km. Wind carried the eruption cloud from this explosion due south and deposited up to 4 mm of ash on Kingstown the capital.

The crater during the eruption

Throughout the explosive period frequent low-level reconnaissance flights were made over the volcano but the continuous steam emission combined with persistent low-level cloud prevented us from seeing into the crater until 17 April at about 13.00 UTC, when a brief view was obtained of the interior of the crater. The 1971 island was still largely intact except to the north where it was breached by a hole approximately 100 m in diameter connected to the crater lake. It was not possible to determine the extent or depth of the crater lake. On 21 April the first clear photographs of the interior of the crater were obtained. About one-quarter of the 1971 island remained, forming a horseshoe shape around a steaming vent. South and east of the island remnant, the floor of the crater was covered with mud and other debris but a portion of the crater lake remained in the northern and western parts, connected to the vent by a breach in the northern part of the island. Persistent heavy cloud at the summit then made aerial reconnaissance extremely difficult but on 30 April conditions improved and it was possible to see that only a fragment of the island remained. Most of the floor was covered with mud around a strongly steaming central depression. On 3 May the presence of a small dome-shaped object in the eastern crater rim was reported to be steaming vigorously. Aerial reconnaissance on 7 May confirmed the presence of a fresh, black, dome-shaped mass of lava ~200 m in diameter rising to ~30 m above the crater floor. The crater itself was infilled with debris to above the level of the pre-eruption lake surface and was apparently dry except for a small pond abutting the northern edge of the new lava mass. Strong steam emission was taking place at the western edge of the lava and at several other places on the crater floor. The lava itself was draped with sediments which eroded rapidly over the next two days. Further aerial inspections were on 8, 9 and 11 May during which time the lava mass increased in size by about 40%. Between 14 and 16 May the lava mass was surveyed from the crater rim and from the crater floor. At this time it was approximately elliptical in plan with major axes 400 m from north to south and 300 m from east to west. Its sides sloped upwards at an angle of about 45° to a flat top with a slight depression in the centre. A small crescent-shaped pond abutted the lava on the north side while to the south-west and south-east two relics of the 1971 island protruded through the new crater floor. During the next month the lava continued to grow, mainly by lateral spreading over the crater floor, at a rate estimated to be $0.5–1 \times 10^6$ m^3 d^{-1}. Growth was most rapid to the north and north-east and least rapid to the south and south-east where the remants of the 1971 lava restricted lateral spreading. The depression on the top of the lava gradually disappeared to be replaced by a slight rise from which several low ridges radiated. On 18 June the diameter of the lava was 715 m from east to west and about 700 m from north to south. Its height was estimated to be 110 ± 10 m and its total volume of order 25×10^6 m^3.

Seismological observations

Three short-period vertical-component seismographs were in operation in St Vincent at the beginning of the eruption. Two of these (SVV and SVB in Fig. 2) were linked by radio telemetry to Trinidad where the signals were displayed visually on drum recorders and simultaneously recorded on magnetic tape for later analysis. The third station (SVT) operated with a standard

Table 1 Major oxide analyses of Soufrière samples

photographic recorder in St Vincent. On 14 April, a second magnetic tape recorder and visual monitor were set up at Belmont. Initially signals were recorded from SVV, SVB and from SLW, 80 km to the north in St Lucia, BDH, 170 km to the east in Barbados, and BBD, 250 km to the north in Dominica. Other seismograph stations, monitored in Trinidad, were in Grenada, 130 km south of St Vincent and in Trinidad and Tobago. Throughout the eruption the larger network recorded only regional seismic activity at a level known to be normal for this region. In the vicinity of St Vincent the network has a detection capability for earthquakes down to about magnitude (m_b) 2.5, and no earthquake above this magnitude originated within 100 km of the Soufrière throughout the eruption. Between 15 and 21 April four more radio-linked stations were added to the network in St Vincent. On 28 April SVT was linked in to the system and on 12 May a station was established on the crater rim. The final station configuration is shown in Fig. 2. From the time that stations SVV and SVB became saturated by continuous tremor at 04.30 UTC on 13 April they remained saturated until about 13.00 UTC on 15 April (for the entire early period of explosive activity). At about this time the level of continuous tremor had declined sufficiently for individual events to be recognisable, and since then the numbers of events have fluctuated as shown in Fig. 3. A more thorough analysis of these events will be discussed elsewhere but, in the terminology of Minakami[9], they are of two types—explosion-type earthquakes and B-type earthquakes. The relative time control between the stations of the network is $\sim\pm0.02$ s but the continuous background tremor throughout the eruption has made it difficult to identify first onsets to better than 0.1 s. The pattern of arrival times at stations in St Vincent makes it clear that all the events originated within 1 km of the crater, but the emergent nature of the onsets and the station distribution (particularly the lack of a station very close to the crater rim) make it impossible to estimate focal depths by conventional first-arrival techniques to a precision better than ±5 km. A reasonably good correlation was established between some of the larger explosion-type events and actual explosions visible at the crater. Both types of event were propagated with very low phase velocities and attenuated rapidly with distance which suggests they were of extremely shallow origin.

Perhaps the most interesting seismological feature of the eruption has been the continuous tremor. Apart from the initial 57-h period of very strong tremor, there have been several subsequent periods of tremor (Fig. 3). Each major explosive outburst has been accompanied by strong tremor, but no clear premonitory pattern emerged by which we could predict the onset of individual explosions by more than a few minutes. No earthquakes have been reported to be felt during the eruption, but several people who were within 10 km of the volcano on the morning of 13 April reported feeling continuous tremor, and the tremor accompanying the 17 April explosion was reported to be felt at Georgetown.

Petrography and analysis of ejecta

Thin sections of fresh material from bombs and pyroclastic flow deposits show that plagioclase phenocrysts with oscillatory-zoned rims and shadow-zoned cores are the main crystalline phases. Some crystals, the largest of which are 10–12 mm long, contain gas bubbles and inclusions of olivine and glass. Other phenocrysts are pale yellowish-green clinopyroxene with rare and almost colourless orthopyroxene. Accessory amounts of subrounded olivine as well as euhedral amphibole and disseminated magnetite are also present. Fine-grained gabbroic cumulate inclusions 5–20 mm in diameter are common in many of the blocks and bombs. The matrix is glassy to microcrystalline. Tephra collected at Grantley Adams Airport, Barbados, on 14 April 1979 were analysed at the University of Rhode Island and the glasses from the same ashes were analysed by electron microprobe. The results are shown in Table 1. Whole-rock analyses of scoria collected from the 14 April Larikai pyroclast flow and of a composite scoria and ash fall at Belmont on 17 April were carried out at the Smithsonian Institution by electron microprobe. A sample from the 1971 lava was also analysed on the same instrument and all the results are shown in Table 1. The tephra produced in the eruption was found to contain two glass populations of dacitic and andesitic composition. The occurrence of banded scoria blocks in the new air-fall deposits on St Vincent confirm that the 1979 event was a mixed-magma eruption.

Comments

A full assessment of the size and significance of this eruption, the most intensively ever monitored in the Lesser Antilles, cannot be made until all the data have been analysed or indeed until the eruption comes to a definite end. Since 13 April, samples have been collected of the ejecta from each major explosion and the extent and thickness of these deposits have been constantly assessed. After each explosion the air-fall deposits other than those on the uppermost slopes had almost completely vanished within 48 h and the deposits on the volcano itself were partially reworked by mudflows during the same period. These observations illustrate the need for rapid sampling and also suggest that eruptions of the Soufrière which are of great significance from the point of view of public safety may leave little or no permanent stratigraphic record. Several tens of thousands of volcanic earthquakes, as well as many hours of continuous tremor, have been recorded on magnetic tape and most of the individual explosion since 15.15 UTC on 13 April have been extensively photographed, and the explosion of 17 April was particularly well recorded. The air-fall ash thicknesses of Fig. 2 are generally 1–2 orders of magnitude less than the thicknesses reported from the same locations after the explosions of 7–8 May 1902. Similarly the pyroclastic flows seem to have travelled much shorter distances than in 1902 when pyroclastic flows frequently reached the sea both east and west of the crater. Judging by these rough criteria we estimate that the total volume of pyroclastic ejecta in 1979 has been one or two orders of magnitude less than in 1902.

Widespread artefact-bearing gravels overlie Pliocene diatomites in the plain of Gadeb (7°02'–7°13'N, 39°15'–39°28'E) at 2,300 m in east-central Ethiopia. The diatomites are from 2.7 to 2.35 Myr old, and the bulk of the Developed Oldowan and Acheulian tools are between 1.5 and (?) 0.7 Myr old. Drying out of the Pliocene lake, deposition of the gravels, and erosion of the Webi Shebele gorge reflect the interplay of volcano-tectonic and climatic events, as does the biostratigraphy of the Pliocene diatomites.

A PROBLEM for prehistorians and earth scientists working in East Africa is how to distinguish depositional changes in lakes and river valleys which stem from climatic oscillations from those related to volcanic and tectonic activity[1–4]. A further difficulty near the African Rift Valleys is that much of the older field evidence has been faulted, tilted, removed by erosion, or buried so that conflicting interpretations of the age and significance of Plio–Pleistocene deposits in East Africa make it difficult to reconstruct prehistoric environments during this critical period in hominid evolution with appropriate precision[5–8]. Accordingly there is a real need to seek out areas in Africa in which complete sequences of late Cenozoic deposits have been preserved from erosion and tectonic disruption, and in which evolutionary changes in the plants and animals may be related to prehistoric cultural changes, set within a radiometrically dated time scale. Recently mapped and excavated fluvio–lacustrine deposits at 2,300 m on the plain of Gadeb, near the headwaters of the Webi Shebele River, in the volcanic uplands of east-central Ethiopia (Fig. 1), seem to fulfil these prerequisites, and may well become a stratigraphic datum for the rest of East Africa.

At Gadeb, artefact-bearing fluviatile sands and gravels overlie Pliocene lacustrine diatomites and clays (Fig. 2). The fluviatile sediments occupy erosional channels, and postdate a 2.35 ± 0.2 Myr old welded tuff which overlies the lake deposits. A marked erosional unconformity separates the lacustrine and fluviatile series.

The stone implements associated with the fluviatile sediments are manufactured mostly of local basalt and welded tuff, and belong to the Developed Oldowan and Acheulian traditions[9,10]. The occasional obsidian tools must, on present knowledge, have come from sources in the Rift some 100 km away (W. H. Morton, personal communication). Most, but not all, of the artefact-bearing sediments postdate a 1.5 Myr pumice deposit, and may be older than 0.7 Myr if the initial result from a palaeomagnetically reversed sample above the occupation floors is confirmed by the scores of other samples now being analysed (Fig. 3) (A. Cox and L. Lee, unpublished data). Details of the K–Ar and palaeomagnetic dating techniques will be given elsewhere.

Pliocene Lake Gadeb came into being as a result of one or more lava flows which dammed back the east-flowing drainage of the ancestral Webi (Figs 1 and 2). The issue of hominid occupation of the Gadeb upland plains is related to the problem of when and why Lake Gadeb finally dried out, which is in turn associated with major tectonic and climatic events in Ethiopia. In this article we interpret the regional stratigraphy and outline the environmental changes at Gadeb during the past 3 Myr. Later papers will deal in detail with the geochronology, prehistory, palaeo-ecology and sedimentology, and are part of a

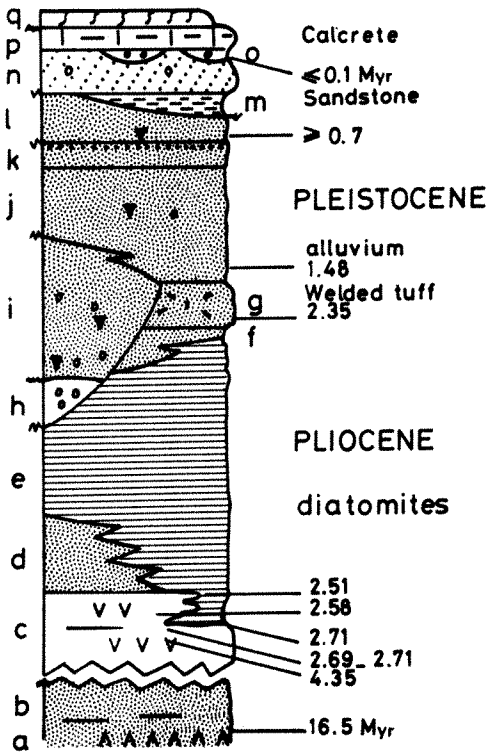

Fig. 2 Generalised Plio–Pleistocene stratigraphic sequence at Gadeb plain, Ethiopia. Ages are based on K–Ar dates (16.5–1.48 Myr), (?) reversed palaeomagnetism (≥0.7 Myr), and presence of Middle Stone Age artefacts (≤0.1 Myr). Letters denote lithological units: a, trachyte; b, tuff; c, basalt; d, feldspathic sands; e, diatomite; f, feldspathic/pumiceous sands; g, welded tuff; h, pumice mudflow; i, sands and fine gravels; j, gravelly sands; k, tuff and palaeosol; l, pumice sand; m, laminated pumice silts; n, pumiceous conglomerate sandstone; o, fine basalt gravels; p, calcrete caprock; q, modern clay soil. Inverted triangles denote developed Oldowan and Acheulian stone tools.

multi-disciplinary study of the Plio–Pleistocene environments and prehistory of east-central Ethiopia.

Geological setting

Flanked by once glaciated[11,12] and now wooded Tertiary volcanoes which rise to over 4,000 m, Gadeb plain is now drained by the Webi Shebele, one of the great rivers of East Africa (Fig. 1). The Webi rises some 250 km south of Addis Ababa, meanders eastwards across the present plain (and former floor of Pliocene Lake Gadeb), and descends suddenly over several high falls into its gorge, initially 300 m deep. Horizontal beds of ash, tuff and trachyte capped by several resistant basalt flows crop out in the sides of the gorge, which is entrenched into an older valley with gently sloping sides. Basalts from five sections along and upstream of the gorge have yielded middle to late Pliocene ages, and a single trachyte sample from ~130 m below the shoulder of the gorge has a K–Ar age of 16.5 ± 0.2 Myr, indicating a Miocene to Pliocene age for the volcanic rocks beneath the Gadeb lake deposits.

The oldest diatomites exposed along the edge of the gorge overlie basalts dated to 4.35 Myr, 2.69–2.71 Myr, and 2.51 Myr (Fig. 2). At one place a 2.71 Myr flow overlies baked and contorted diatomites. We conclude that Lake Gadeb had formed by 2.71 Myr, and that the basaltic eruptions responsible for creating the original lava dam persisted for some time after the lake had come into being. The nearby shield volcanoes of the Bale Mountains are a possible source of these lavas.

During the Pliocene uplift and faulting associated with the creation of the Ethiopian Rift, tuffs and ignimbrites were laid down over the floor and margins of the Rift[13,14]. These pyroclastic deposits thin out away from the Rift, and only a single thin Pliocene welded tuff dated to 2.35 Myr extends as far as Adaba village near the foothills of the Bale Mountains (Fig. 1). By this stage, Pliocene Lake Gadeb had dwindled to a series of small lakes and swamps situated near the centre of the basin.

Pliocene Lake Gadeb

The lacustrine deposits comprise a very pure basal diatomite (3×10^3 valves per mg), passing progressively upwards into initially diatomaceous clays and silts. Intercalated sandy horizons within the diatomite sequence indicate short-lived lake regressions. Abundant interstratified ash bands reflect intermittent volcanic activity within the Rift Valley throughout the existence of Lake Gadeb. The approximate extent of the former lake may be deduced from deposits which attain elevations up to 2,340 m (Fig. 1). The lake had a minimum surface area of 155 km^2 and was at least 40 m deep.

To reconstruct the ecological history of the lake, the diatom assemblages in four closely correlated reference sections were analysed (Figs 1 and 4). Taken together, these four sections encompass the entire lacustrine sequence, a total of over 31 m

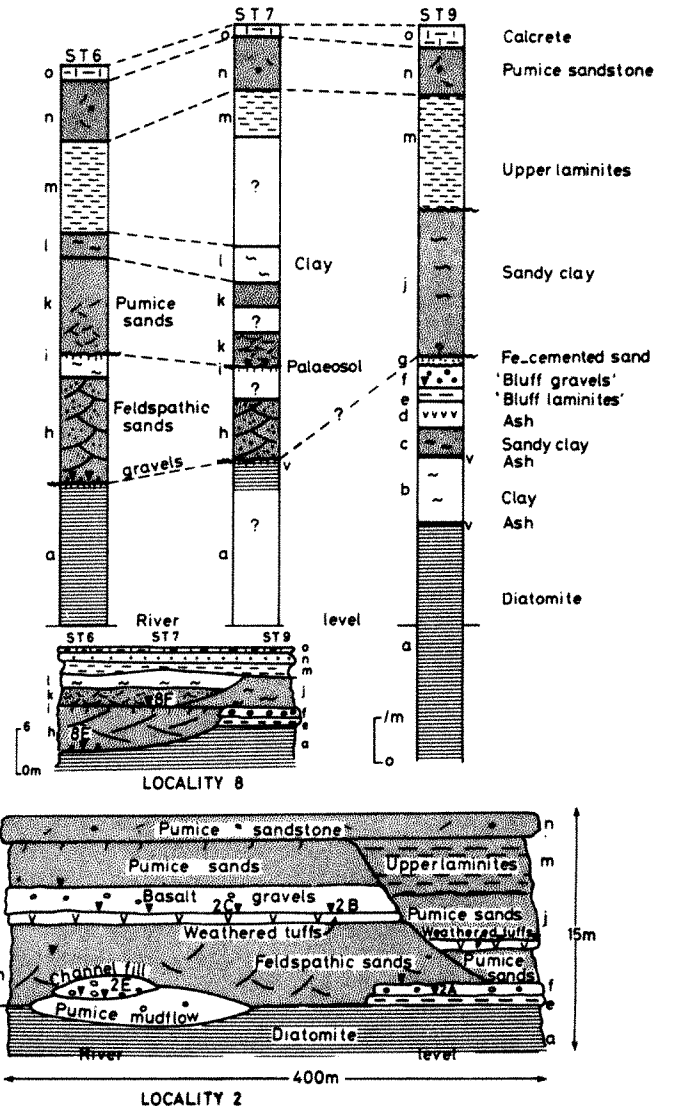

Fig. 3 Pleistocene fluviatile sequence at localities 2 and 8, Gadeb plain, Ethiopia. Inverted triangles denote artefact concentrations (Developed Oldowan and Acheulian), ST is a geological step trench, and zig-zags are unconformities. 2E, 8E and 8F are major archaeological excavations.

(Fig. 4). Analysis of 215 diatomite samples reveals a rich flora (345 taxa) with very diverse assemblages (Fig. 4). The abundance of extinct species makes a detailed ecological interpretation difficult, but it is possible to deduce the ecological influence of certain factors. The relative proportions of planktonic and littoral species allow us to distinguish fluctuations in lake level. On this basis, four major stages, separated by minor regressions, may be recognised (stages I to IV, Fig. 4). Each stage is defined by a set of characteristic species. Despite slight increases in salinity during regressions, the lake was always oligohaline. By comparison with the lakes of East Africa[15], Lake Gadeb was always of low to moderate alkalinity (2–10 mequiv. l^{-1}). Deposition of airfall or reworked ash was also influential, because during stages I and II there is a noticeable peak in the abundance of the ecologically little-known *Stephanodiscus minutus* and *S. tenuissima* immediately above each ash band (Fig. 4). Previous workers have noted that *Melosira* spp. require abundant dissolved silica[15,16], and that an influx of volcanic ash can trigger their sudden proliferation[17].

The increase in detrital material towards the top of the lake sequence reflects a fall in lake level, also evident in the diatom flora, followed by progressive drying out of the lake during stage IV. Nevertheless, the silts and sands that accumulated during the final regression of Pliocene Lake Gadeb are sometimes interrupted by thin diatomaceous horizons laid down during a brief return to more swampy conditions. These discontinuous lenses cannot be correlated from one section to the next, and only occur in a few sections near the centre of the basin. We conclude that these deposits do not point to a renewed transgression of the original lake, but in fact correspond to its fragmentation into a series of small swamps, the position of which varied with the changing locus of drainage. These ponds persisted during the ensuing phases of river erosion and deposition contemporary with the arrival of tool-bearing hominids.

Arrival of tool-bearing hominids

As the level of Lake Gadeb fell, alluvial gravels and sands were distributed across the plain by rivers flowing down from the adjacent uplands. Abundant stone flakes, chopping tools, bifaces and cleavers, found in association with broken animal bones, indicate that tool-making groups were occupying the central parts of the plain at this time[9]. The absence of any stone tools or waste flakes in alluvium beneath and immediately above the intact lake deposits at section 18 (Fig. 5), suggests that there were few, if any, tool-making hominids here at this time. Concentration of slightly abraded implements on the floors of shallow channels formed during the final stages of the dwindling lake (Fig. 3) suggests that the hominids probably camped alongside these channels, hunting the animals that lived in, or came down to drink at, the shallow lake remnants near the centre of the basin.

Plio–Pleistocene river deposits

The fluviatile sediments that overlie the diatomites are highly variable in particle size and composition, ranging from fine pumice silts to feldspathic sands to basalt gravels. Nevertheless, after allowing for facies changes, a progressive change is evident in the depositional pattern with time.

At localities 2 and 8, the youngest diatomites are capped by an indurated and very distinctive layer of horizontally bedded tuffaceous mudstones (the 'bluff laminites' of Fig. 3). Unconsolidated ashes and clays sometimes underlie the mudstone band, which is in turn overlain by a horizontal bed of coarse basalt gravel (the 'bluff gravels' of Fig. 3), often iron-cemented and containing bone chips and stone tools at locality 2 (excavation 2A, Fig. 3). These tools are the oldest discovered at Gadeb so far, and are separated from younger tool-bearing gravels by a sharp erosional break at the base of bed h (8E Fig. 3).

Above the unconformity at locality 8 are tool-bearing basaltic gravels and feldspathic sands which are capped by a palaeosol on which was found a hippo butchery site (8F Fig. 3), well preserved

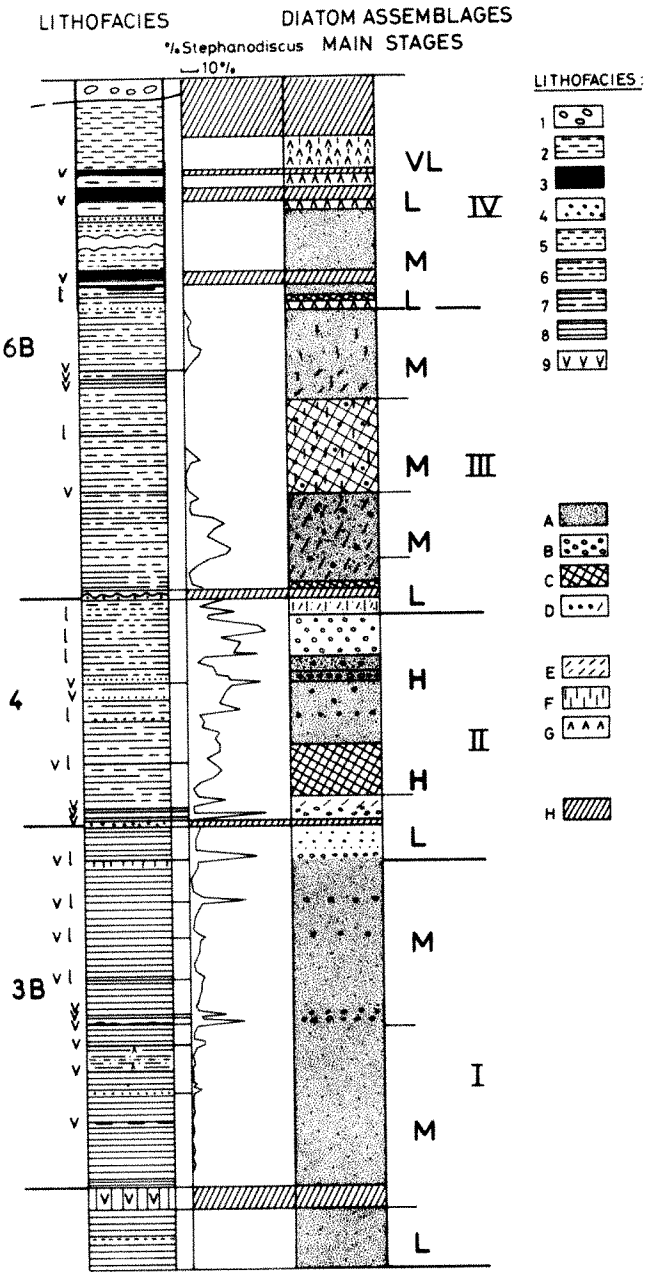

Fig. 4 Pliocene lacustrine sequence at Melka Likimi sites 3B, 4 and 6B, Gadeb plain, Ethiopia. Key to lithofacies: 1, gravels; 2, clay; 3, ash; 4, sand (reworked ash, pumice or feldspars); 5, silt; 6, silty diatomite; 7, clayey diatomite; 8, pure diatomite; 9, basalt; v, volcanic ash; l, limonite band. Key to dominant diatom assemblages: planktonic and tychoplanktonic spp.: A, *Fragilaria* spp.; B, *Stephanodiscus* spp.; C, *Melosira* spp.; D, *Cyclotella* spp.; benthic and epiphytic spp.: E, *Synedra* and *Achnanthes* spp.; F, *Navicula* spp.; G, *Nitzschia, Cymbella, Epithemia, Rhopalodia* and *Pinnularia* spp., H, no diatoms. Lake level: VL, very low; L, low; M, intermediate; H, high.

beneath a thick layer of finely cross-bedded pumice sands. Several weathered and reworked clayey tuffs overlie these sands and are in turn covered by a wedge of finely laminated pumice silts (the 'upper laminites' of Fig. 3) and by a resistant ledge of pumiceous sandstone conglomerate (Fig. 3).

At locality 2 we also have the sandstone caprock and the eroded bluff gravels. Beneath the upper laminites (m) is a thick channel-fill deposit of loose pumice sand (j) similar to that at locality 8. Unconformably beneath the pumice fill are pumice sands and tool-bearing gravels (Fig. 3, locality 2, 2B, 2C) and a

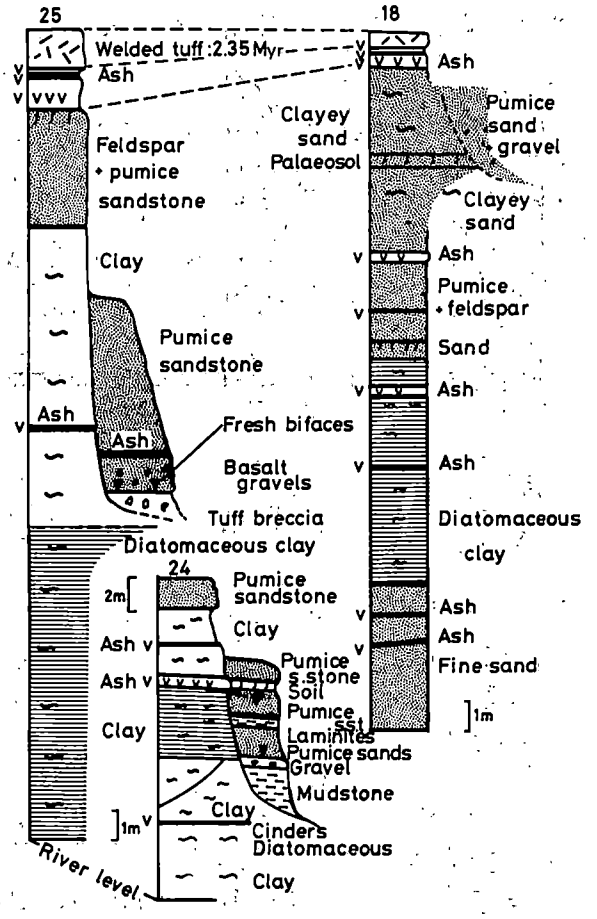

Fig. 5 Plio–Pleistocene depositional sequence at localities 18, 24 and 25, Gadeb plain, Ethiopia. The mineralogy and refractive indices of the three tephra units beneath the welded tuff at localities 18 and 24 show that they are identical at both localities. Inverted triangles denote prehistoric artefacts.

sterile weathered tuff overlying gravelly feldspathic sands (h) similar in appearance to those at locality 8. A conspicuous channel-fill within these sands contains abundant bones and artefacts (Fig. 3, locality 2, 2A), and is in turn underlain by a pumice mudflow deposit dated to 1.48 Myr (Fig. 3).

From the base to the top, therefore, the fluvial depositional sequence at 2 and 8 begins with basaltic gravels and feldspathic sands, then alternates between feldspathic and pumiceous sediments, and culminates in massive deposits of pumice. These changes reflect the incidence of major eruptive phases in the Rift, the nearest source of pyroclastic deposits. Episodes of widespread deposition of basalt gravels at Gadeb rather than of ash imply eruptive quiescence in the Rift at least as much as they imply effective erosion in the Bale Mountains, so that it would be unwise to attempt a purely climatic interpretation of these gravels.

Figure 5 shows how the pumice sandstones and basaltic gravels containing very fresh welded tuff bifaces (section 25) are banked up against the littoral diatomaceous clays and overlying clays, sands and ashes. The 2.35 Myr welded tuff at sections 24 and 25 was breached by vertical erosion before the deposition of the gravels, and before the arrival of the hominids who quarried and flaked the welded tuff.

Erosion of the gorge

Above the head of the gorge the Webi is entrenched some 20 m into the Plio–Pleistocene lake and river deposits described above. Below the falls there is a thin scatter of basalt pebbles and rolled bifaces for 6 km along the southern shoulder of the gorge until the junction with the Hako River[9] (Fig. 1). Scattered diatomite remnants crop out along both flanks of the gorge, but only above the falls do thick artefact-bearing gravels rest directly and discordantly on the Pliocene diatomites. Before gorge incision the deposits east of the present falls were co-extensive with those to the west.

The continuous sedimentation in Lake Gadeb means that any variations in the lake flora must reflect changes in water composition and temperature. The lake was already very low before deposition of the welded tuff, and evolved into a series of shallow swamps thereafter. Fluviatile downcutting to nearly 20 m below the level of the nearly horizontal tuff caprock was followed by deposition of some 10–15 m of Pleistocene alluvium in the centre and west of the Pliocene lake basin. Renewed downcutting is evidenced by two erosional terraces cut into the diatomites near Melka Likimi (Figs 1 and 4), and a final phase of aggradation is evident upstream.

The initial phase of downcutting took place between 2.35 and 1.48 Myr ago. The final phase is younger than the deposition of the unconsolidated gravels with Middle Stone Age flakes at locality 8, and is presumably late Pleistocene[18].

Uplift of the Ethiopian Plateau seems to have accelerated during the Cenozoic, although it was episodic rather than continuous[19]. A recent estimate[20] of 0.1 mm yr^{-1} for the late Pleistocene would imply, if valid also for the southeastern Plateau, an uplift of perhaps several hundred metres since the first hominids occupied the plain of Gadeb.

Tectonic and climatic implications

The above discussion suggests several consequences. First, that major erosion of the Webi gorge may be comparatively recent, although initial downcutting is certainly of late Pliocene to early Pleistocene age. Second, if uplift has indeed accelerated from early to late Pleistocene times, we might expect to find at Gadeb a progressive increase in montane forest pollen with time. Superimposed on this trend would be the pollen fluctuations related to glacially controlled changes in temperature and precipitation. A detailed comparison between pollen spectra and the Pliocene diatom assemblages of Lake Gadeb should allow us to separate tectonically induced changes in lake level from those directly related to regional climatic oscillations. Such analyses are now in progress.

Conclusions

An uninterrupted sequence of diatomites accumulated in a Pliocene lake (Lake Gadeb) which formed when lava flows ponded the drainage of the Webi Shebele in the uplands of south-central Ethiopia some 2.7 Myr ago. The lake shrank progressively until shortly before 2.35 Myr ago, when tuff from the Ethiopian Rift covered the lake deposits and preserved them from erosion. Analysis of the Gadeb diatoms constitutes the first study in Africa of a thick, continuous and well dated lacustrine sequence. As such, it is of great biostratigraphic interest, and will enable correlations to be made with Plio–Pleistocene diatom floras elsewhere in Africa[21–23] and Europe[24–26]. As the lake level fell, rivers from the adjacent uplands deposited sand and gravels across the former lake floor. Hominids occupied the plain between ~1.5 and (?) 0.7 Myr ago, using mostly local sources of basalt and welded tuff to manufacture their implements. Final downcutting by the Webi through the tool-bearing gravels and lake diatomites, and erosion of the Webi gorge, seem to be related to accelerated tectonic uplift during the later part of the Quaternary.

We thank Professor J. Desmond Clark for inviting us to do this work, the NSF for funds, Macquarie University for leave, Dr Allen Cox for preliminary palaeomagnetic results, Dr Getaneh Assefa and the late Dr W. H. Morton for advice and support in Ethiopia, Professor Pierre Rognon and Paul M. Bishop for stimulating discussion, and Monique Cholley for drawing the figures.

Hominid occupation of the East-Central Highlands of Ethiopia in the Plio–Pleistocene

J. Desmond Clark & H. Kurashina

University of California, Berkeley, California 94720

Stone artefacts and fossil evidence suggest that hominids did not reach the high plateau of Ethiopia until ~1.5 Myr ago. Contact between hominids of the plateau and the Rift Valley seems likely.

THE archaeological localities described here, excavated during the winters of 1975 and 1977, are situated in the Plain of Gadeb on the South-East Plateau of Ethiopia at elevations between 2,300 and 2,400 m in the upper reaches of the Webi Shebele River (see Fig. 1 of ref. 1). Except where human interference has disrupted it, the present vegetation pattern of short, montane grassland with stands of *Acacia* and occasional relict junipers and, in the mountains, *Podocarpus* and juniper forests, is not greatly different from that of the Plio–Pleistocene. The long and very complete sedimentary sequence and its palaeoclimatic and palaeoecological interpretation is summarised by Williams *et al.* in the accompanying article[1].

No stone artefacts or other signs of hominid activity have been found in the earlier part of the succession and cultural evidence appears only when the Pliocene Lake Gadeb had mostly dried out, following the breaching and down-cutting of the dam and the formation of the gorge, at a date between ~1.5 and >0.7 Myr on K/Ar and palaeomagnetic reversal evidence (G. H. Curtis and A. Cox, personal communication). The artefacts occur on palaeosols adjacent to the banks and in association with the gravels of shallow stream courses draining into the ponds and swamps that still occupied the lower and central parts of the basin. The cultural horizons are exposed by the meanders of the main river and so occur in the more central parts of the exposed floor of the former Pliocene lake. Examination of the southern flanks near the base of the Bale Mountains (which rise to over 4,000 m) produced only occasional artefacts of Developed Oldowan type suggesting that the more outlying parts of the basin may have been less favourable living places for hominids.

The evidence from Gadeb suggests that hominids appeared on the Ethiopian high plateau only after ~1.5 Myr perhaps ~1.0 Myr ago, at a time when *Homo erectus*, the maker of the Acheulian and Developed Oldowan industrial complexes[2,3], was moving out of the drier and warmer, though well-watered, more low-lying traditional habitats in the Rift Valley and on adjacent parts of the African plateau and was beginning to colonise most ecological niches in Africa—including the high plains.

The Pliocene sediments exposed in the central parts of the basin appear to have been mostly laid down in standing water and so are unlikely to have artefacts associated with them. Only towards the western end, at geological sections 24 and 25[1], is a palaeosol preserved beneath a capping of welded tuff dated to 2.35 Myr (G. H. Curtis personal communication). This palaeosol has yielded part of an elephant molar, perhaps an early form of *Elephas recki*, but the horizon must be examined before we can be certain that no artefacts or other evidence of hominid activity are associated with it.

Developed Oldowan occurrences

The main artefact localities are shown in the accompanying article[1], the most important being localities 2, 8 and 25 and those that line the eastern shoulder of the Webi Gorge downstream from the Falls to the Hako confluence. With the possible exception of the Acheulian artefacts from the gravels above the Gorge, which cannot, as yet, be tied into the stratigraphic sequence upstream, the oldest assemblages recovered occur at locality 2 and come from the iron-stained base of the ferruginous gravels (f) that rest on the mudstones (e) which, in turn, overlie disconformably the Pliocene diatomite. A small excavation, 2A, showed that artefacts and bone fragments occurred in a relatively limited area of 6×2.5 m and, as they are mostly moderately abraded, were not in primary context. The artefacts comprise a handaxe, choppers, core-scrapers, polyhedrons, irregular hard-hammer flakes and the cores from which they were struck, together with a few regularly retouched tools, all from basalt cobbles. A selection is shown in Fig. 1. The assemblage is provisionally classified as Developed Oldowan but the retouched scrapers show a refinement more usual with the Acheulian tradition. Although similar occurrences of choppers,

heavy and light duty scrapers and polyhedrons are known from other late Lower and Middle Pleistocene localities in Africa, these are, perhaps, the first such assemblages to have been assigned to the Developed Oldowan B outside the type locality at Olduvai Gorge.

The next oldest Occurrence excavated is found several hundred metres east of 2A, in a channel fill cut into a pumice mudflow dated to 1.48 Myr (G. H. Curtis, personal communication). This channel is 30–40 m wide and filled with alternating deposits of silt, fine sand and clays with occasional thin, discontinuous layers of basalt cobbles, rounded angular fragments of ignimbrite, artefacts and bone in a matrix of sand and fine gravel. An excavation (2E) of 40 m^2 was made in one such horizon towards the eastern edge of the channel and uncovered a hominid activity area, apparently occupied at a time when the channel floor was temporarily exposed. The horizon dips gently from east to west towards the centre of the channel where the gravel is ~10 cm thick but, towards the bank the artefacts and cobbles rest directly on the underlying clayey silt. The silts and clays overlying this horizon contain many pollens and diatoms and the extent to which this Occurrence has been reworked by fluvial action can be assessed by the fact that the diatoms still preserve their fragile spiney structure which would undoubtedly have been broken had there been any turbulence in the water that laid down these beds. Most of the artefacts are slightly (basalt) to moderately (welded tuff) abraded, suggesting that 2E represents a primary context site which has suffered some but no extensive resorting before being fairly rapidly covered by renewed depositional activity.

The assemblage, 1741 specimens, is typical of the Developed Oldowan B Complex (pages 258–281 of ref. 2), comprising the usual range of choppers, core-scrapers, polyhedrons and subspheroids, flake scrapers and modified pieces together with cores, flakes and flaking waste (Fig. 2). There are also six handaxes and one cleaver, all exhibiting hard-hammer technique and showing a lack of the refinement normally found with the Acheulian assemblages at Gadeb. Note that unmodified cobbles comprise only 18.4% and simply split cobbles 4.2% of the total. If the assemblage were all fluvially deposited one would have expected many more cobbles than artefacts which suggests that the former may have been carried onto the site by the hominids to use for making tools.

A number of fossil bone fragments and teeth, ranging from fresh to moderately abraded, are associated with the artefacts. Bones, mostly broken into small pieces, and teeth came from hippopotamus, elephant, various bovids, zebra and pig. No concentrations could be discovered but the assemblage is an indication of the game animals available on the high plateau at this time (faunal identifications at Gadeb by D. Geraards and S. Edwards are provisional).

Higher in the 22-m sequence at Locality 2, are stratified basalt gravels with artefacts, overlying weathered tuffs. Two small excavations made in 1975 exposed parts of two further concentrations of Developed Oldowan B character, both in channel fills with, in each case, no significant resorting by subsequent stream action. The earlier occurrence (2C) rested on the weathered tuffs and was covered by fine, current-bedded sands ~1 m thick. A total of 622 artefacts, with some small, unidentifiable bone fragments, came from a 3.5 m × 1.5 m excavation and comprise 12.5% shaped and modified pieces and 87.4% unmodified waste: 66 are shaped tools—choppers, polyhedrons, 5 rather poorly-made handaxes, 4 other bifacially worked artefacts and 27 small scrapers on flakes, flake fragments and chunks, the commonest form being a single-side scraper. There are also 12 pieces with modified edge damage. The artefacts showed no discernable orientation or concentration and were fresh to moderately abraded.

The 2B site, a little higher in the basalt gravels, yielded 589 artefacts from a 2 × 4 m excavation, shaped tools representing 9.3%, modified 0.3% and unmodified waste 90.3%. Again the assemblage can be classified as Developed Oldowan B with the usual choppers, polyhedrons and scrapers. There are also one proto-biface, one handaxe and one cleaver, again poorly-made in comparison with those from the Acheulian. When compared, all three of these Locality 2 assemblages (2B, 2C and 2E) are seen to be similar. In addition, comparison with assemblages of this Complex from East Africa confirms that the Gadeb occurrences belong with the Developed Oldowan B, or perhaps C (from Beds III and IV at Olduvai Gorge), although this has, as yet, not been described in detail[4–6].

Acheulian occurrences

The earliest Acheulian assemblages yet found at Gadeb occur at Locality 8 associated with basalt gravels and felspathic sands resting on an erosional unconformity cut down into the later Pliocene diatomites. This horizon has been excavated in three places—two (8A and 8D) in 1975 and the third (8E) in 1977[1]. The first two were moderately small but that at 8E exposed ~100 m^2 of the occupation horizon (Fig. 3). Again, the context is a shallow stream channel cut across the floor of the Pliocene Lake Gadeb and draining into the central lakelets and swamp. The small 8A excavation produced the surprising number of 1,849 artefacts of which 251 were handaxes and cleavers, most

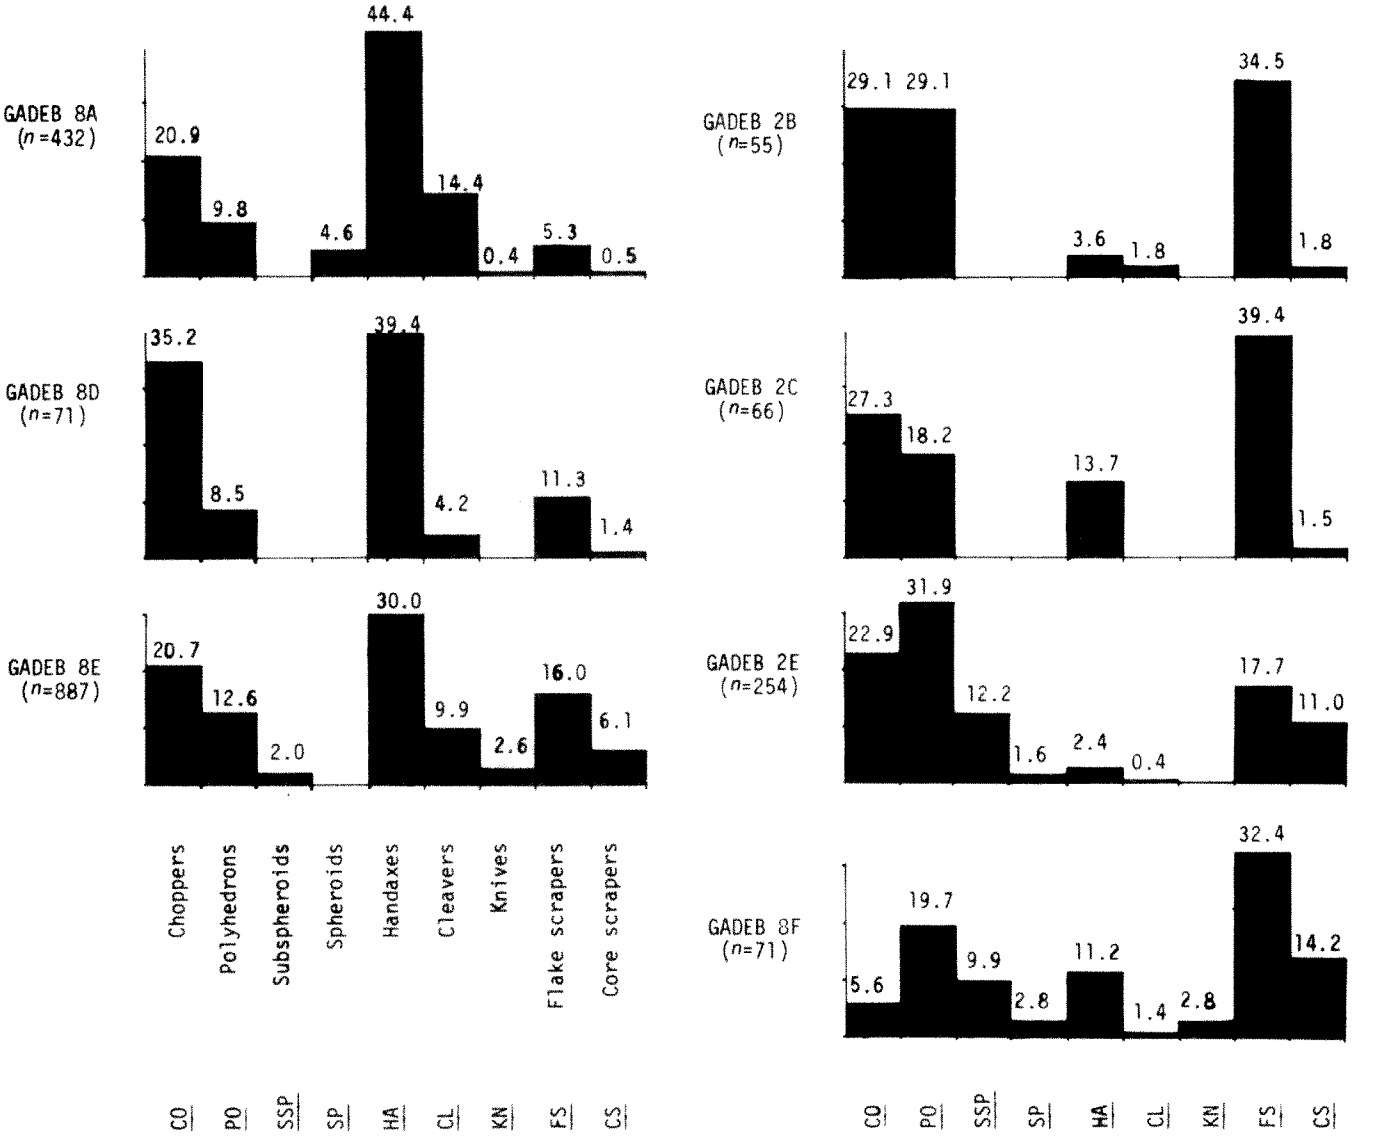

Fig. 2 Histograms comparing Acheulian (left) and Developed Oldowan (right) tool-kits from excavated sites at Gadeb, east central Ethiopia. Each division on the vertical axis represents 10 per cent.

moderately to heavily abraded and their alignment and imbrication show clearly that the assemblage had been incorporated in the stream gravels. Excavations 8D and 8E were ~30 m apart and exposed the edges of a channel and its banks to the south-east. To the south and west the gravel was 10–15 cm thick while at the eastern end the artefacts rested directly on the diatomite. The 8D excavation (3×5 m) revealed a primary context concentration of artefacts and fossil bone, including two complete hippopotamus canines and fragmentary remains of bovids, zebra and elephant as well as unidentifiable bone fragments. The 487 artefacts were mostly fresh to slightly abraded and 14.6% were shaped tools, 1.6% modified and 83.8% unmodified waste. Bifaces comprise 43.6% of the shaped tools—mostly handaxes with three cleavers—the remainder being flake scrapers, choppers and spheroids indistinguishable from similar tools associated with the Developed Oldowan.

The 8E excavation in the same occupation surface yielded 20,276 artefacts and a small quantity of fauna. Except for a nearly complete zebra mandible, the bone consisted mostly of unidentifiable small fragments and isolated teeth, the commonest of these being hippo represented by two complete, large incisors and several molars and molar fragments. The next commonest group were the bovids followed by zebra. Again, there were no bone accumulations and it would appear that butchery was not a major activity here or at the other Acheulian sites excavated at Gadeb.

The greater number of artefacts occurred in the northern half of the excavation due, probably, to gravitation down-slope. No preferred orientation is apparent and the bifaces lay flat on the surface (Fig. 3). 45% of artefacts are moderately, and 26% slightly abraded; 15% are fresh. It seems that the assemblage has suffered slight movement, though insufficient to disperse or significantly alter the concentration before it was buried under felspathic sands with silt and clay lenses in the lower part.

The composition of the 8E assemblage is given in Fig. 2: 4.4% of the pieces are shaped tools, 10.5% are modified or show edge damage and 50% is unmodified waste the remaining 35% being cobbles and split cobbles. The commonest shaped tools are bifaces: handaxes (25%), cleavers (9.9%), knives (2.6%) and other (or broken) bifaces (4.9%). The next most numerous are flake scrapers (16.0%) among them several continuously retouched and convergent forms. The other tools—choppers, polyhedrals, spheroids and core scrapers—are similar to those found with the Developed Oldowan (Fig. 4).

The raw material is basalt and ignimbrite with a little chert and obsidian. The ignimbrite was obtained from outcrops, the nearest today being several kilometres to the west and south. The ignimbrite handaxes were made from large flakes struck

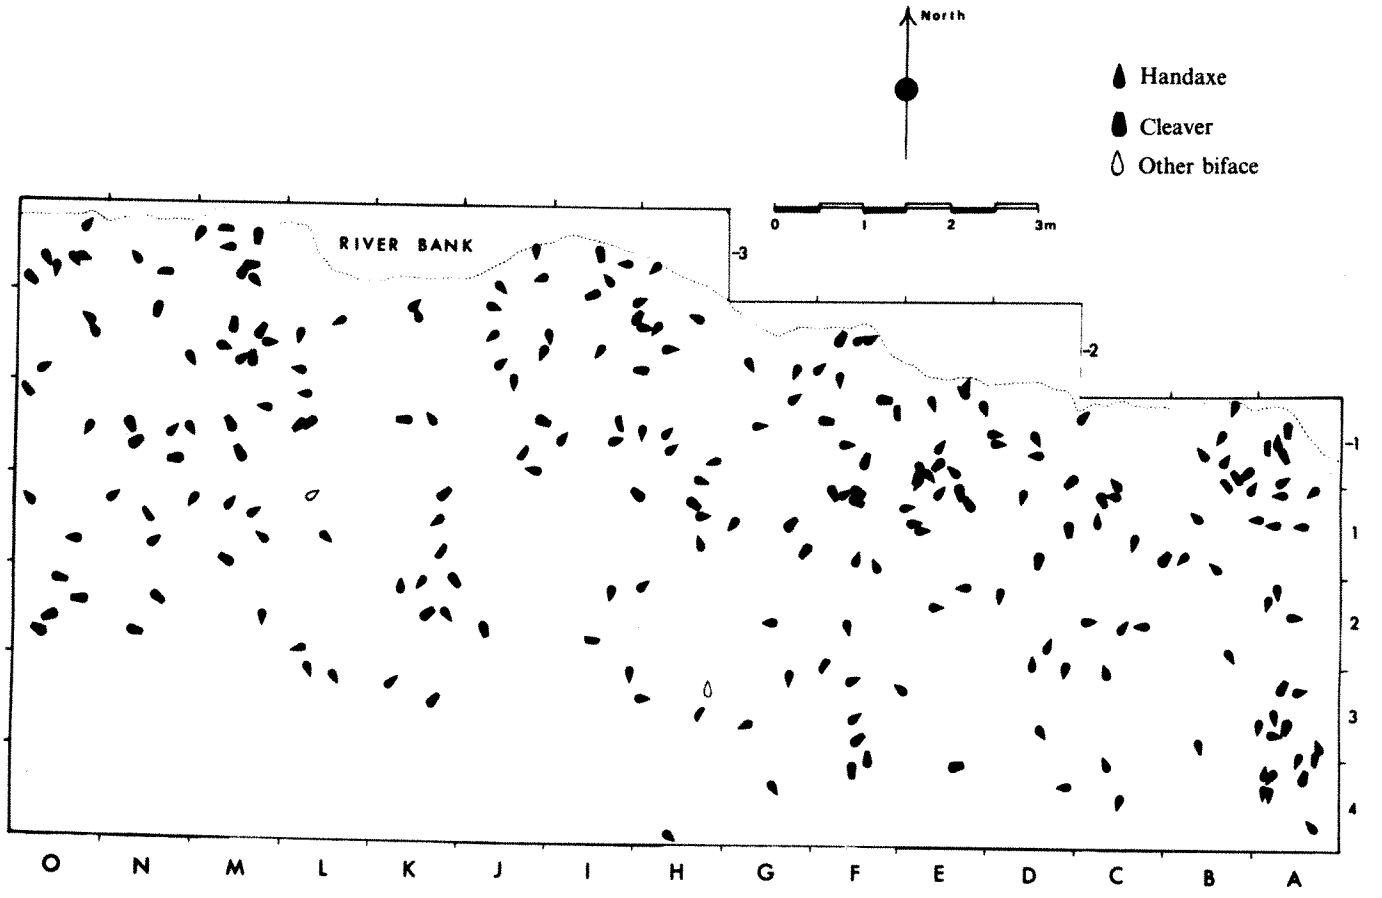

Fig. 3 Plot of the distribution and orientation of the bifaces (handaxes, cleavers) on the Acheulian occupation horizon at Gadeb 8E, 1977.

from these outcrops and are larger, broader, thicker and more elongated than those made from basalt cobbles which are generally ovate or long ovate in plan form (Fig. 4, no. 9). The large flakes from cobbles, retouched as handaxes and cleavers, usually have a flat release face which often results from splitting a cobble by throwing (N. Toth, personal communication). Bifacial handaxes are commonest but an interesting form occurs flaked only on the release face and exhibiting inverse retouch; occasionally, these are also minimally retouched on the cortex face. Flake scrapers also sometimes show this form of retouch. (Biface plan forms in relation to raw material at 8E are shown at Fig. 5).

Four ovate handaxes in obsidian from 8E are of special interest since they—or the raw material—must have come from a considerable distance. No sources of obsidian are known on the South-east Plateau the nearest being to the west in the Rift or on the escarpment edge ~100 km away[1]. This distance is appreciably greater than any hitherto known for the Lower Palaeolithic and has important implications, therefore, for movement or group contacts between the Plateau and the Rift.

Among the modified or utilised artefacts are 11 cobbles, or rounded fragments, with a pit formed in the centre of one face by hammering with some pointed implement (Fig. 4). Similar pitted stones have been found at Olduvai Gorge (upper Bed II and Beds III/IV)[7], and on the Developed Oldowan horizon Gomboré I at Melka Kunture on the Ethiopian Plateau[8]. They are believed to be anvils used with hammer stones in the bipolar flaking method although other uses cannot be excluded.

The occupation floor also yielded several fragments of heavily weathered basalt which, when rubbed, give a red pigment. None of the pieces show unquestionable evidence of rubbing but the possibility should not be ignored. Several pieces of welded tuff showing what appears to be alteration by fire were also recovered, including several together in a concentration. Palaeomagnetic measurements by Dr M. Barbetti, University of Adelaide, on samples from the 8E activity area have produced suggestive, but not conclusive evidence for the use of fire by Acheulian man at Gadeb.

Butchery site

On the surface of the palaeosol overlying the felspathic sands covering the Acheulian occupation at Locality 8 (Fig. 3, ref. 1), was found, at Excavation 8F, a discrete concentration of artefacts associated with part of a butchered hippo (Fig. 6). The 385 fresh or slightly abraded artefacts are presumed to be in primary context; 18.4% are shaped tools, 7.8% are modified or show edge damage and 3% are miscellaneous pieces (Fig. 2). Only 51.2% represent unmodified waste and 19.2% are cobbles or split cobbles all of which must have been carried onto the site. The commonest tools (32.4%) are small flake side-scrapers; polyhedrons and spheroids also account for 32.4% and there are 14.1% of core-scrapers. Choppers are few (5.7%) and bifaces are represented by a cleaver, three small, poorly-made handaxes, two knives, similarly of crude workmanship and five miscellaneous forms. Among the modified/utilised artefacts are 17 flakes and flake fragments. This tool-kit could have been used in butchering the hippo and the polyhedrons, spheroids and some of the small tools were found in close association with the bones.

Technically this assemblage belongs and is assigned to the Developed Oldowan B complex. The palaeosol is overlain by silts with reversed magnetism and has an age of $\geq$0.7 Myr.

Quarry site

An important Acheulian ignimbrite quarry and workshop was discovered at the end of the 1977 season at Locality 25, ~6.5 km west of locality 2 where basalt gravels, overlain by ash and

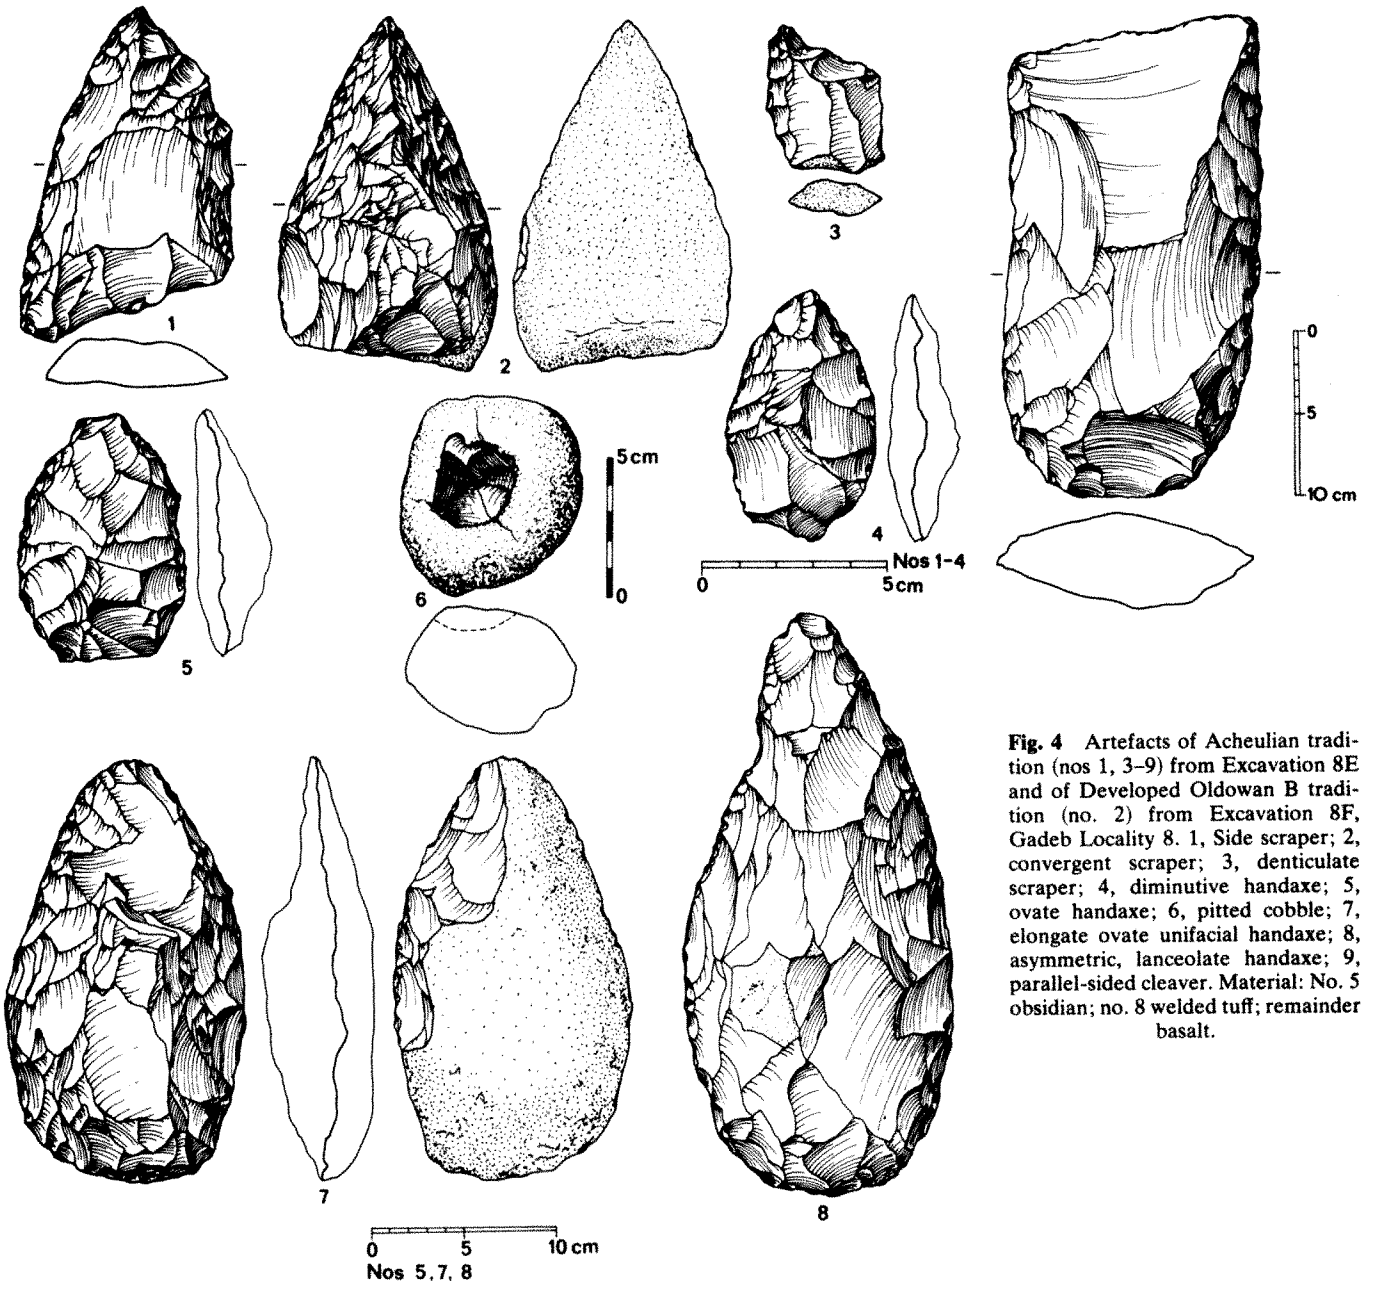

Fig. 4 Artefacts of Acheulian tradition (nos 1, 3–9) from Excavation 8E and of Developed Oldowan B tradition (no. 2) from Excavation 8F, Gadeb Locality 8. 1, Side scraper; 2, convergent scraper; 3, denticulate scraper; 4, diminutive handaxe; 5, ovate handaxe; 6, pitted cobble; 7, elongate ovate unifacial handaxe; 8, asymmetric, lanceolate handaxe; 9, parallel-sided cleaver. Material: No. 5 obsidian; no. 8 welded tuff; remainder basalt.

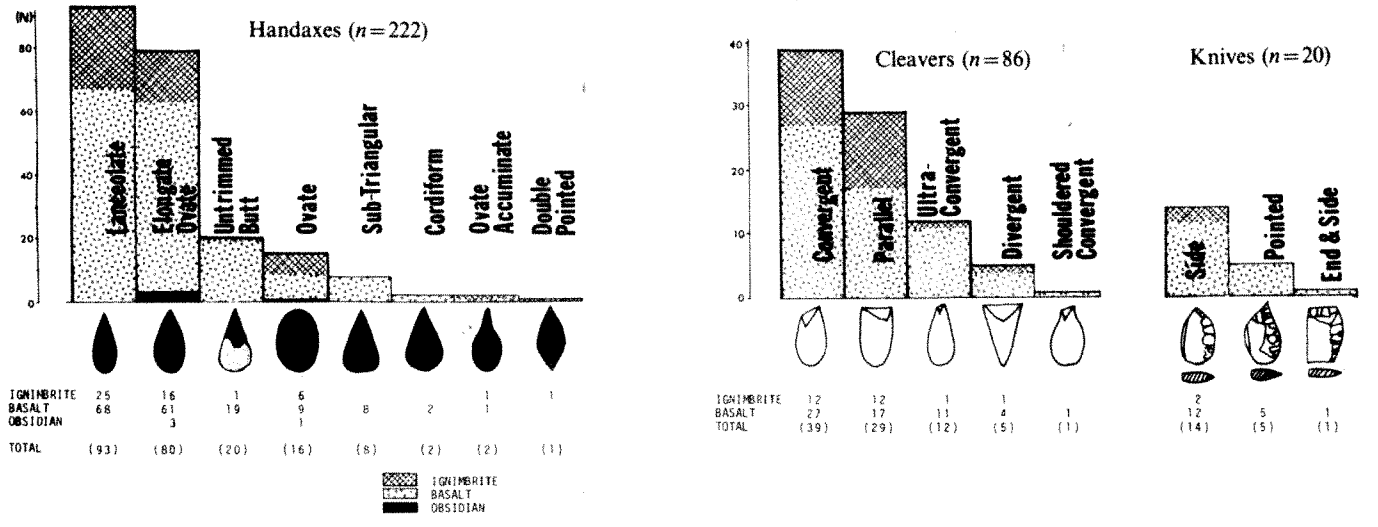

Fig. 5 Acheulian biface forms and raw materials at Gadeb 8E, 1977.

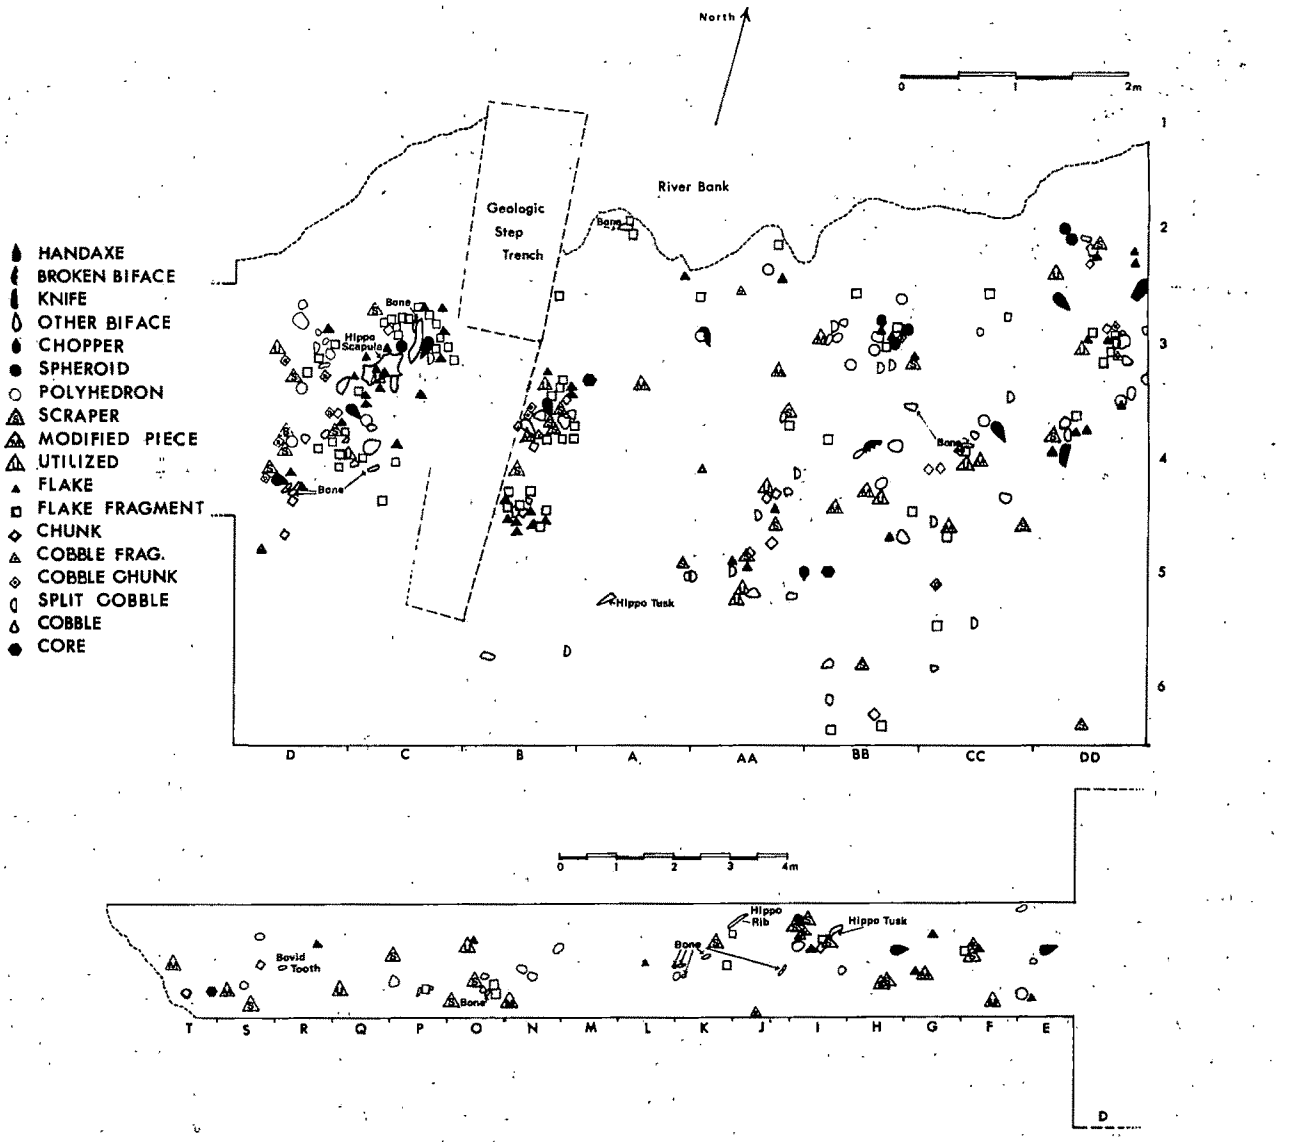

Fig. 6 Plan of the hippo butchery concentration on the palaeosol at Gadeb 8F, 1977.

pumice sandstone, fill an erosion channel cut into the earlier Pliocene sediments capped by welded tuff (Fig. 5 of ref. 1). A small trial trench yielded 112 Acheulian artefacts in fresh condition together with fossil bone. The ignimbrite had been 'mined' by knocking off large flakes from the outcrop and fallen blocks and there is no evidence of the proto-Levallois technique. This is one of the few sealed Acheulian quarry sites known to us but, without further work, it cannot be correlated directly with the succession at localities 2 and 8.

Either contemporary with or somewhat later than the 8F butchery site are two well-made, fresh Acheulian cleavers with some fossil bone which had come from the base of the bedded pumice sands (j) in the deep channel fill beneath the 'upper laminites' (m) at locality 2 (Fig. 3 of ref. 1). These are the youngest of the Lower Pleistocene Occurrences at Gadeb, as no tools have, as yet, been found in the Pumice Sandstone that caps the succession.

In the gravels at the top of the Webi Gorge between the Falls and the Hako confluence, concentrated patches of Acheulian bifaces and other tools occur in secondary context. At the Hako confluence itself, residual gravel patches yielded weathered, but not especially water abraded, choppers, cores and flakes of Developed Oldowan form. Clearly, therefore, Acheulian man was present during the final breaching of the dam and while the river was cutting back upstream as far as the lower of the two existing waterfalls.

Conclusions

It seems probable that hominids did not penetrate to the high plateau until after the Acheulian complex appeared in the Rift after 1.5 Myr ago. The Gadeb sites show an alternating sequence of Acheulian and Developed Oldowan occurrences dating between ~1.5 and >0.7 Myr. These must have been contemporary traditions the main distinguishing feature being the bifaces with the Acheulian, whose makers were, therefore, engaged in biface-related activities not common with the Developed Oldowan. The bone waste found on the sites, however, indicates that butchery was more commonly practised by the makers of the Developed Oldowan using the chopper, polyhedron and small tool element. The sites were generally close to or in stream courses, as elsewhere in East Africa and Ethiopia[9,10] and, while remains of grazing animals are found, the preferred food animal appears to have been the hippo. The Gadeb assemblages show generally close similarities, though with local variation, with those from sub-Saharan Africa as a whole.

The hominids seem to have been relatively far ranging and contact between plateau and Rift seems likely. *Homo erectus*, even at this unusually early time, may have been experimenting with pigment at Gadeb and also with fire; the latter, perhaps, induced by the cold temperature of the plateau since this must be one of the highest altitudes at which assemblages of this time range have been found in either Africa or Eurasia.

We thank Dr M. A. J. Williams and his associates, Mrs F. Dakin Williams, Dr D. Adamson, the late Dr W. H. Morton, and Dr Getaneh Assefa for geomorphic and stratigraphic interpretation; Professors G. H. Curtis and A. Cox for K/Ar and palaeomagnetic reversal dating; Dr M. Barber for NRM–TRM measurements; Drs R. Bonnefille and F. Gasse for palaeobotanical and limnological results; Mr D. Geraads and members of the team from Berkeley for faunal identifications and help with the excavations; Mrs B. C. Clark for editorial and secretarial assistance; Judith Ogden and Alison Galloway for the illustrations and the Ethiopian Government Antiquities Service and our Oromo workmen at Gadeb. The localities discussed here were excavated by an international team sponsored by the University of California, Berkeley and financed by the NSF.

Isolation and characterisation of a yeast chromosomal replicator

D. T. Stinchcomb, K. Struhl & R. W. Davis

Department of Biochemistry, Stanford University School of Medicine, Stanford, California 94305

A yeast DNA sequence that behaves as a chromosomal replicator, ars1 *(autonomously replicating sequence), has been isolated. On transformation,* ars1 *allows autonomous replication of all co-linear DNA. The replicator can integrate into other replication units and can function in multimeric form. The 850-base pair* ars1 *element has no detectable homology to other yeast sequences. Such replicator-containing plasmids can be used for the isolation of DNA sequences in yeast cells as well as for the study of chromosomal DNA replication.*

THE replication of a cell's genome must be properly controlled to harmonise with the many other functions required for cell division. In bacteria, the rate of DNA replication is controlled at the onset of synthesis[1,2]. The initiation event occurs at a single site on the bacterial chromosome[3]. This initiation site or origin of replication has been genetically defined as the 'replicator' (ref. 4), an element that allows replication of all DNA attached to it. Several prokaryotic replicators have been isolated (see ref. 5 for examples) and their further biochemical and genetic analysis will help elucidate the molecular mechanism(s) that control the initiation of bacterial DNA synthesis.

How is DNA replication controlled in the larger genomes of eukaryotes? An abundance of physical data indicate that eukaryotic chromosomes are organised into tandem replication units (reviewed in refs 6–8). The rate of DNA chain elongation seems to be the same for all the replication units in a cell, whereas different units initiate DNA synthesis at different times. Furthermore, initiation is a non-random event. Replication units begin synthesis in a defined order and individual units demonstrate the same temporal specificity in successive divisions. However, the paucity of genetic and biochemical evidence means that it is impossible to determine whether such replication units are strictly analogous to prokaryotic chromosomes. For example, it has been proposed that initiation occurs not at a specific DNA sequence, but at a random site, determined solely by the spatial arrangement of the DNA within the highly structured chromosome[6,7].

During our studies on transformation of the yeast, *Saccharomyces cerevisiae*, we identified a segment of chromosomal DNA that could replicate without integrating into the yeast genome[9]. Here we further characterise this autonomously replicating segment. Its behaviour suggests that the DNA sequence contains a eukaryotic chromosomal replicator.

*ars*1: A chromosomal replicator

A 1.4-kilobase pair *Eco*RI endonuclease-generated DNA fragment, containing the centromere-linked *trp*1 gene was isolated (D.T.S. and R. W. Davis, in preparation). This fragment (Sc4101) was inserted into the *Eco*RI cleavage site of the bacterial plasmid, pBR322 (ref. 29) (Fig. 1). The resulting plasmid is termed YRp7. Covalently closed, supercoiled YRp7 DNA was used to transform a *trp*1$^-$ yeast strain. The efficiency with which these cells were transformed to Trp$^+$ was approximately 1,000-fold higher than the efficiency observed with other segments of yeast chromosomal DNA[9]. Furthermore, the high frequency of transformation was associated with autonomous replication. When DNA was isolated from these transformants and analysed by restriction endonuclease digestion and DNA–DNA hybridisation, the transforming sequences were detected as supercoiled, circular DNA and were not found integrated into the host genome. Presumably, the higher frequencies of transformation arise because autonomous replication allows heritable expression without requiring chromosomal integration via a less frequent recombination event. Thus, high transformation efficiency can be used as an indicator for autonomous replication of these hybrid molecules.

To test whether autonomous replication might be due to the particular sequences at the yeast/pBR322 junctions, the transformation efficiency of YRp7′, which contains the Sc4101 insert inverted relative to YRp7, was measured. Both YRp7 and YRp7′ gave rise to 2,000–4,000 Trp$^+$ colonies per μg DNA. As other yeast sequences (for example the *his*3, *leu*2, *ura*3 structural genes[9,11,12]) fail to replicate autonomously when inserted into pBR322, it is likely that the element that permits autonomous replication is located on Sc4101 itself. This was further investigated by inserting the Sc4101 DNA fragment into YIp1, a *his*3-containing yeast vector that transforms at low efficiency via integration into the host chromosome (Fig. 1). As expected, the frequency at which YRp7–Sc2605 and YRp7′–Sc2605 DNAs transformed *his*3$^-$ to His$^+$ was also high (2,000 His$^+$ colonies per μg DNA). Sc4101 has been joined to many

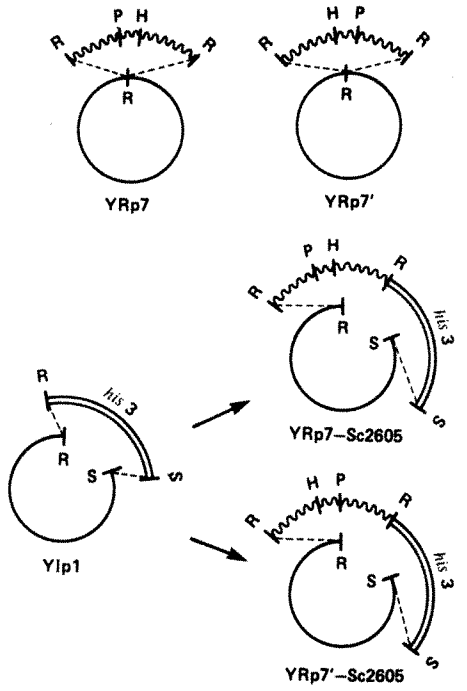

Fig. 1 Structure of several yeast replicator plasmids. Solid lines depict pBR322 plasmid sequences, wavy lines represent the *trp*1-containing 1.4-kilobase pair yeast fragment (Sc4101) and open bars a 6.0-kilobase pair yeast fragment (Sc2605) that contains the *his*3 structural gene. Not to scale. YRp7 and YRp7′ were constructed by the ligation of an *Eco*RI digest of λgt-Sc4104 and pBR322 as described previously[9]. YRp7–Sc2605 and YRp7′–Scα605 were similarly constructed by insertion of the Sc4101 fragment in either orientation into the *Eco*RI cleavage site of YIp1. *Eco*RI was the gift of Marjorie Thomas. Other restriction endonucleases and T4 DNA ligase were from New England Biolabs or Bethesda Research Laboratories and were used as directed. After ligation, the hybrid molecules were transformed[31] into trpC9830, an *E. coli* strain lacking *N*-(5′-phosphoribosyl)anthranilate isomerase. The presence of Sc4101 was then determined by testing for complementation of the bacterial lesion by the yeast *trp*1 gene (D.T.S. and R. W. Davis in preparation). The orientation and fidelity of the purified plasmid DNA were assessed by restriction endonuclease digestion and horizontal agarose gel electrophoresis[10]. Transformation of D13-1A (*a trp*1 *his*3-532 *gal*2 *SUC*2 *mal*$^-$) was carried out as described previously[9]. The transformation efficiencies for the YR plasmids cited in the text were determined on several separate occasions using other yeast vectors to control for experimental variation.

other yeast and bacterial sequences, producing hybrid molecules 4 to 50 kilobase pairs in total length. All these Sc4101-containing DNAs exhibited high frequency transformation and, concomitantly, replication in the absence of recombination with the host genome (S. Scherer, T. P. St. John, D.T.S. and K.S., unpublished observations). These data are consistent with the idea that Sc4101 contains, in addition to the structural sequence for the *trp*1 gene, a genetic element that allows autonomous replication, which we will call *ars*1 (for autonomously replicating sequence).

Yeast cells can be transformed simultaneously by two different DNA species at high frequency[13]. For example, when a mixture of YRp7–Sc2605 and YRp12 (YRp7′ with a 1 kilobase pair yeast DNA fragment carrying the *ura*3 gene inserted at the *Ava*I endonuclease cleavage site[12]) DNA was added to a *ura*3$^-$*his*3$^-$ strain, Ura$^+$His$^+$ co-transformants arose at the same frequency (2,000–5,000 colonies per μg) as Ura$^+$ or His$^+$ transformants. So, in these transformation conditions, DNA is saturating and each yeast cell is capable of receiving multiple DNA molecules. This observation can be used to design a *cis*/*trans* test for *ars*1 function. If *ars*1 functions in *trans*, co-transformation of a *his*3$^-$*trp*1$^-$ yeast strain by YIp1 and YRp7 DNAs should lead to a 1,000-fold increase in His$^+$ colonies compared with transformation by YIp1 alone. However, the mixture of YIp1 and YRp7 DNA gave rise to only 78 His$^+$ colonies per μg DNA. Concurrently, YRp7–Sc2605 DNA gave rise to 2,000 His$^+$ colonies per μg DNA. Thus Sc4101 allows high frequency transformation and autonomous replication of the *his*3 sequence only when located on the same molecule. As *ars*1 is linked to the yeast chromosomal *trp*1 locus and behaves as a *cis*-acting effector of DNA replication, we propose that *ars*1 is a yeast chromosomal replicator.

Autonomously replicating *ars*1 hybrid molecules are unstable

In a minimal medium supplemented with histidine and tryptophan, a *trp*1$^-$ *his*3$^-$ yeast strain will grow with a doubling time of 2.5 h. When transformed by YRp7–Sc2605 to His$^+$Trp$^+$, the strain doubles in 3.5–4 h in the absence of histidine and/or tryptophan. Similarly increased generation times are observed for all other *ars*1-containing transformants, regardless of the selective marker used. It is thus unlikely that the slow growth rate is due to a deficiency in expression of the transformed genes but is due rather to mitotic loss of the autonomously replicating hybrid DNA. In a logarithmically growing minimal medium culture of a *his*3$^-$ strain transformed by YRp7–Sc2605 DNA only 30–50% of the cells are phenotypically His$^+$. If this culture is diluted into a non-selective medium, the proportion of His$^+$ cells drops to 1–5% within 10 generations. The resulting *his*3$^-$ cells do not contain any hybrid DNA as determined by DNA–DNA hybridisation (data not shown).

There are several possible explanations for the mitotic instability of *ars*1-containing hybrid molecules. The isolated replicator may not contain all the information necessary for complete replication during each cell cycle. However, larger DNA fragments that contain additional DNA sequences adjacent to *ars*1 are still mitotically unstable (D.T.S. and R.W.D., in preparation). Alternatively, *ars*1-containing extrachromosomal elements may compete with the host chromosome for limited initiator(s). This is one proposed explanation for the instability of plasmids containing the *Escherichia coli* origin of replication[15,16]. Hybrids containing *ars*1 plasmids may replicate during each cell cycle but may fail to segregate properly during mitosis. In the last case, addition of other DNA sequences controlling chromosomal segregation would be expected to stabilise a replicator plasmid.

Intregation of *ars*1 hybrid molecules

The slow growth of strains containing *ars*1 hybrid molecules results in a strong selective pressure favouring any stably transformed cells. Such transformants can indeed be isolated. After many generations of growth in selective or non-selective conditions, cells were plated on non-selective medium. These colonies were tested for the stability of the transformed phenotype by replica plating to a selective medium. Stable transformants isolated in this way grew at the parental rate in minimal medium. The fate of the transforming DNA was investigated in four independently isolated stable strains (Fig. 2). The diagram at the bottom of Fig. 2 shows the digestion patterns expected for three possible conformations of the foreign sequences. The transforming DNA was identified by hybridisation and co-electrophoresed with the high molecular weight linear host DNA in all four cases (Fig. 2, lanes 1–4). The structure of the integrated DNA in one transformant was analysed by digestion with *Bam*HI endonuclease. The foreign pBR322 sequences in the stable transformant were detected as a single band (Fig. 2, lane 7) co-migrating with the *Bam*HI fragment from an unstable transformant (lane 6) and from the original plasmid DNA (lane 9). These data indicate that YRp7–Sc2605 is integrated at the *his*3 locus without major sequence alteration.

Given the appropriate genetic markers, stable transformants may be directly selected. Fragments containing non-complementing derivatives of the *his*3 gene (the missense mutations *his*3-38 and *his*3–532 (ref. 17), as well as an amber mutation[18] and two deletions[19]) were inserted into YRp7. These hybrid molecules were introduced into a *his*3-532*trp*1$^-$ strain by transformation to Trp$^+$. Although the transformants were initially His$^-$, His$^+$ recombinants could be selected at a frequency of 10^{-5}–10^{-6} per generation. The only exception to this result

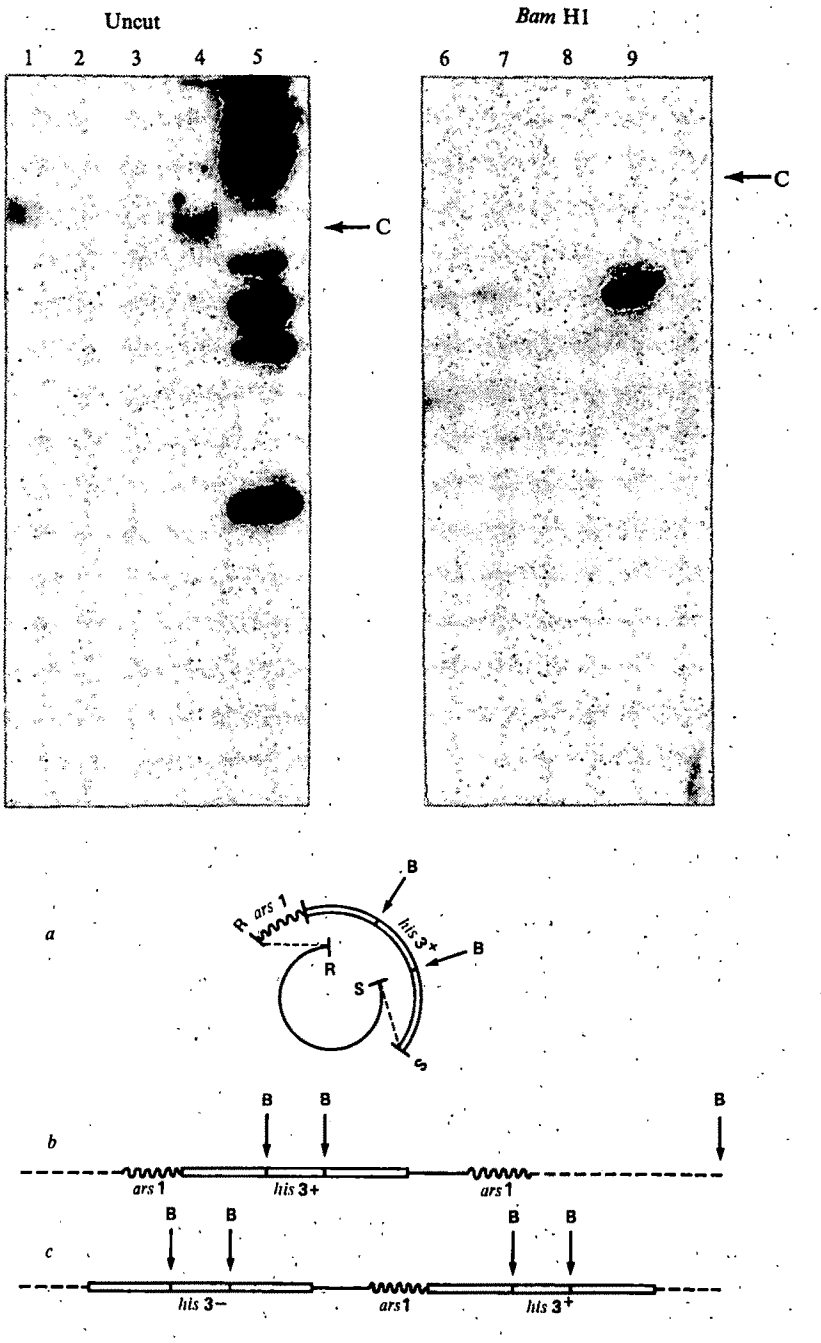

Fig. 2 Analysis of stable *ars*1 transformants. DNA was rapidly purified from transformants grown in minimal media (6.7 g l^{-1} Difco yeast nitrogen base, 2% glucose) as described previously[9]. In 'uncut', the DNA from four stable transformants described in the text was electrophoresed without endonuclease digestion in a 0.4% agarose gel (lanes 1–4). Lane 5 contains the original transforming DNA. The multiplicity of bands (several of which showed lower mobilities than the yeast chromosomal DNA) is apparently due to multimeric and nicked forms of the plasmid. In '*Bam*HI', DNA isolated from an unstable transformant (lane 6), a stable, integrated transformant (lane 7), the parental strain (lane 8), and the transforming plasmid DNA (lane 9) were digested with *Bam*HI restriction endonuclease and electrophoresed on a 0.4% agarose gel. The DNA in each gel was transferred to a sheet of nitrocellulose paper[25]. ^{32}P-labelled pBR322 DNA was prepared by nick-translation[26], heat denatured, and hybridised to the immobilised DNA spectra. These operations were carried out using modifications of the traditional procedures as described in ref. 27. Pictures of the two autoradiographs are presented here. Also depicted are three possible structures of transformed *ars*1 sequences: *a*, unintegrated and autonomously replicating; *b*, integrated by homologous recombination between the *ars*1 sequence and its chromosomal counterpart; and *c*, integrated by homologous recombination between *his*3 sequences. Letter and line designations are as in Fig. 1 with one addendum: B represents the predicted *Bam*HI endonuclease cleavage sites.

occurred when the transforming DNA contained the same *his*3 allele as the recipient yeast strain (*his*3–532), in which case no His^+ recombinants could be isolated. All the recombinants obtained were stable for both His^+ and Trp^+ and grew at the wild-type rate in minimal medium. Hybridisation analysis (as described above) indicated that the transforming DNA had integrated at the *his*3 locus without detectable sequence alteration (data not shown). The frequency of recombination between the *his*3–38 allele (on the transforming plasmid) and the *his*3–532 allele (in the recipient) was roughly the same as the frequency observed when the two alleles were present in a heterozygous diploid yeast strain. In all respects, the integration of *ars*1-containing hybrid molecules seems to be a simple consequence of mitotic recombination.

The organisation of DNA replication in *Saccharomyces cerevisiae* is similar to that of other eukaryotes. Fibre autoradiography and electron microscopy studies indicate that each chromosome is divided into several replication units and the initiation of DNA synthesis for each unit is rigidly controlled[20–23]. The ability of *ars*1 sequences to integrate has implications for this control. We have shown the DNA sequences containing a replicator can stably integrate at other loci. As *ars*1 is located near the centromere of chromosome IV and *his*3 maps on the left arm of chromosome XV, the two loci are probably in different replication units. The observation that *ars*1 can integrate at *his*3 indicates that either initiation of DNA replication at *ars*1 is suppressed in its new position or translocation of a second replicator simply creates a new functional replication unit.

Multimeric forms of *ars*1

Plasmids containing *ars*1 have also been integrated in the *trp*1–*ars*1 region near the centromere of chromosome IV (data not shown). As such a recombination event creates a tandem duplication, it suggests that multimers of a chromosomal replicator function normally. To investigate this further, we examined the *ars* phenotype of monomer, dimer and trimer YRp7.

When YRp7 is propagated in a recombination-proficient bacterial host, monomer, dimer and trimer forms of the plasmid arise. Each of the three forms of the plasmid DNA was purified

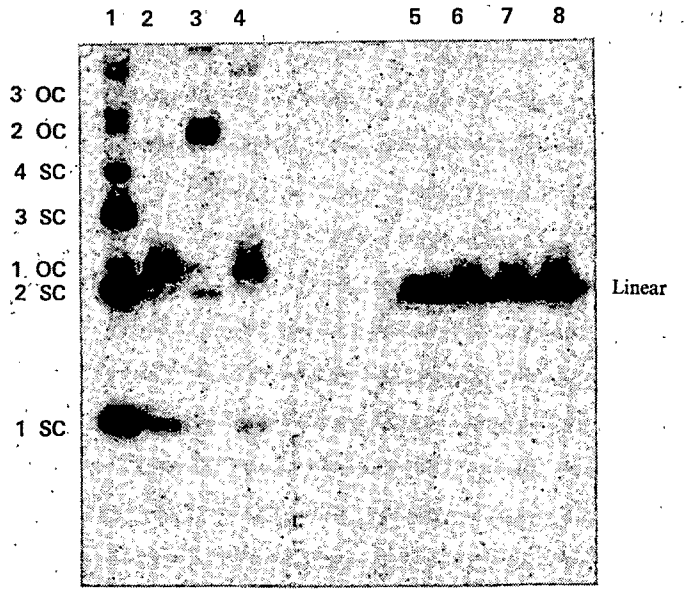

Fig. 3 Autonomous replication of monomer, dimer and trimer YRp7. Plasmid DNA purified from trpC9830 (Rec$^+$) carrying YRp7 was used to transform KM601, a *recA*$^-$*recB*$^-$ *E. coli* strain (gift of Kevin McEntee). Plasmid DNA was rapidly isolated from individual tetracycline-resistant transformants and its size was assessed by agarose gel electrophoresis. Transformants were then picked that contained predominantly monomer, dimer and trimer YRp7. The plasmid DNAs were purified and analysed by restriction endonuclease digestion and agarose gel electrophoresis. Each sample contained some larger multimers, but neither the dimer nor the trimer DNA preparations contained detectable amounts of monomer plasmid and all were free of any gross alterations of the *ars*1 sequences (data not shown). Monomer, dimer or trimer YRp7 DNA was used to transform D13-1A to Trp$^+$. DNA from the transformants was purified, electrophoresed in a 0.4% agarose gel, transferred to nitrocellulose and hybridised to ^{32}P-labelled pBR322 DNA as described in Fig. 2 legend. DNA in lanes 1–4 was uncut while the DNA samples in wells 5–8 were digested with *Bam*HI restriction enconuclease. Lanes 1 and 5 contained 1 μg of wild-type yeast DNA and 2 ng each of purified monomer, dimer and trimer YRp7 DNA. The various multimeric forms are designated by the numbers 1, 2, 3 and 4 (for monomer, dimer, trimer and tetramer) while SC and OC distinguish supercoiled from nicked, open circular DNA. Lanes 2 and 6 each contained 1 μg of DNA purified from D13-1A transformed to Trp$^+$ by the YRp7 monomer form. DNA samples purified from D13-1A transformed by dimer and trimer YRp7 were electrophoresed in lanes 3, 7 and 4, 8 respectively.

by clonal isolation in a *recA*$^-$*recB*$^-$ *E. coli* strain. Transformation of a recombination-proficient *trp*1$^-$ yeast strain to Trp$^+$ occurred at equal frequencies for monomer, dimer or trimer DNA (2,000–5,000 colonies per μg DNA). Strains transformed by each of the three DNAs had identical growth rates and were equally unstable mitotically. The structure of the transforming DNA in such strains was analysed (Fig. 3). Strains transformed with monomer and dimer YRp7 contained, respectively, monomer and dimer autonomously replicating supercoiled circles (lanes 2 and 3). Small amounts of other plasmid forms were detected (dimer in the monomer transformant as well as both monomer and tetramer in the strain carrying the dimer form). A strain transformed with trimer YRp7 DNA contained predominantly monomer plasmid (lane 4). It is unlikely that this isolate arose through transformation by contaminating monomer plasmid in the trimer DNA preparation (see Fig. 4 legend), so appearance of the monomer plasmid probably represents recombinational reduction of the multimeric form. The various circular forms in all three strains contained intact YRp7 sequences as judged by *Bam*HI endonuclease digestion which reduces all multimeric species to a single linear fragment (Fig. 2, lanes 5–8). Thus monomer and dimer YRp7 seem to be functionally equivalent. Some interconversion of multimeric forms occurs, probably by mitotic recombination in the yeast host cells.

A unique feature of *ars*1 is that it is tightly linked to the centromere of chromosome IV. In fact, we considered the possibility that the *ars* phenotype could be caused by a centromeric function. As described above, Sc4101 is capable of both stably integrating at other chromosomal loci and functioning in a dimeric state. If Sc4101 contained a centromere, both of these constructions would represent dicentric molecules which might be expected to undergo sequence alterations when propagated mitotically[30]. As we detected no such alterations, we conclude that Sc4101 is unlikely to have full centromeric function. However, these experiments suggest tests for segregational activity which may lead to the identification of other yeast fragments that contain centromeric sequences.

Delimitation of *ars*1

Sc4101 contains two functions: *trp*1 and *ars*1. To determine the position of the *ars*1 sequences we have constructed several deletions of the 1.4-kilobase pair *Eco*RI-generated fragment. The experimental approach is shown in Fig. 4. Unique restriction endonuclease sites in Sc4101 were fused to unique sites in the pBR322 sequence, deleting parts of both Sc4101 and pBR322. Utilising both YRp7 and YRp7′, it was possible to construct two pairs of complementary deletions; Yp411, Yp413 and Yp412, Yp414. Fragments containing the *ura*3 or *his*3 sequences (known to function when attached to an intact *ars*1 element) were inserted into each of the four deletions. Only Yp413/HIS3$^+$ and Yp412/URA3$^+$ DNAs were capable of transforming *his*3$^-$ and *ura*3$^-$ yeast strains, respectively. Both transformed at high efficiency (again ~2,000 colonies per μg DNA). Yp412/URA3$^+$ had a completely normal *ars*1 phenotype. Strains transformed with Yp413/HIS3$^+$, however, had a greatly reduced growth rate, with a generation time of about 11 h, and an enhanced mitotic instability. Assuming that juxtaposition of the *ura*3 or *his*3 sequences does not effect *ars*1 function, we conclude that the *ars*1 sequence is fully contained within the 850 base pairs between the *Eco*RI and *Hin*dIII cleavage sites and deletion of the 200 base pairs between the *Hin*dIII and *Pst*I sites is an *ars*1 mutation.

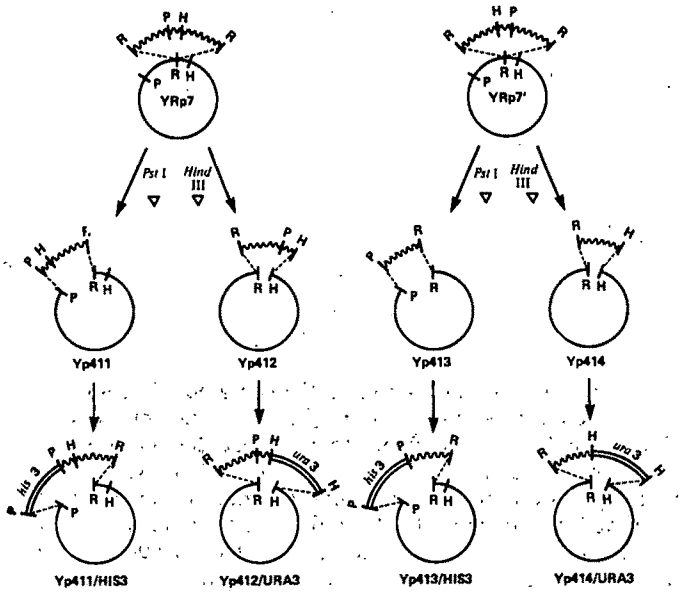

Fig. 4 Deletion analysis of Sc4101. Both *Pst*I and *Hin*dIII restriction endonucleases have unique cleavage sites in Sc4101 and pBR322. Digestion followed by circularisation and ligation (as described in Fig. 1) results in deletion of pBR322 and yeast sequences. The plasmids in the second line, derived in this manner from YRp7 and YRp7′, were identified by selecting the appropriate drug resistance after transformation of *E. coli*. Yeast structural genes were then inserted at the now unique *Pst*I or *Hin*dIII cleavage sites. The *his*3-containing yeast DNA fragment (Sc2710) was prepared by *Pst*I digestion of pGT2-Sc2605 (ref. 9) while the *ura*3 fragment (Sc2904) originated from *Hin*dIII cleavage of λ590–Sc2710 (ref. 12). The resulting plasmids shown in the second line were identified by selection for complementation of *his*B and *pyr*F lesions and for the appropriate drug resistances following transformation of the *E. coli* strains *his*B463 (ref. 28) and MB1000 (ref. 12). The structures of all of the molecules shown were confirmed by restriction endonuclease digestion and agarose gel electrophoresis. Line drawings and letterings are as described in Fig. 1 legend and text.

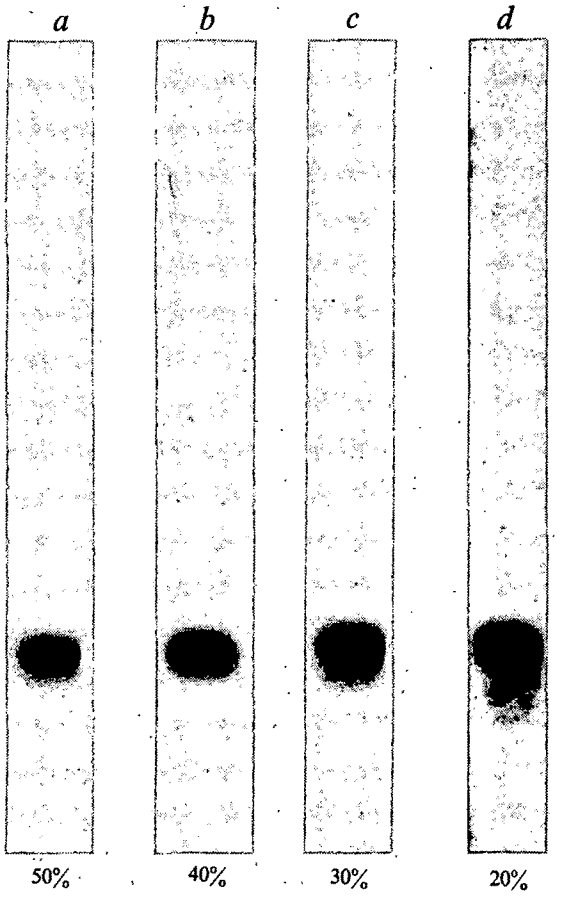

Fig. 5 Yeast sequences homologous to *ars*1. Yeast DNA was digested with *Eco*RI endonuclease and electrophoresed in a 0.6% agarose slab gel. The resulting *Eco*RI restriction spectra were transferred to nitrocellulose and then cut into four strips. After *Eco*RI digestion of YRp7 and gel electrophoresis, Sc4101 was purified by binding the DNA to a glass fibre filter (M. W. McDonnell and R.W.D., in preparation). The isolated fragment was then nick-translated. 10^6 c.p.m. of ^{32}P-labelled Sc4101 DNA was hybrised to each nitrocellulose strip in 5XSSPE (0.75 M NaCl, 50 mM $NaPO_4$, 5 mM EDTA), 0.2% SDS with 50% (v/v), 40%, 30% and 20% formamide (strips *a*, *b*, *c* and *d*, respectively). Each strip was washed in its own hybridisation conditions and autoradiographed. Long exposures were used to try to detect faint bands.

Are sequences homologous to *ars*1 found elsewhere in the yeast genome?

Using measured values for the DNA elongation rate and the total size of the yeast genome, it was estimated that a minimum of 70 initiations must occur if the cell is to replicate its DNA fully during the S phase of the cell cycle[22]. These other chromosomal replicators may have DNA sequences in common with *ars*1.

In an attempt to detect *ars*1 sequences present elsewhere in the yeast genome, ^{32}P-labelled Sc4101 DNA was hybridised to a restriction endonuclease spectrum of yeast DNA. The hybridisation conditions were varied to allow fragments with a significant proportion of mismatched base pairs to anneal. As shown in Fig. 5, even in the least stringent conditions (Fig. 5*d*), only the single homologous 1.4-kilobase pair fragment hybridised to Sc4101. The conditions used would have required at least 75% homology to *ars*1 (over a 500-base pair region) for hybridisation to occur. Alternatively, other yeast replicators probably have less than 20 sequential base pairs in common with *ars*1.

The usefulness of hybrid molecules containing *ars*1

We have previously discussed some of the uses of plasmids containing the Sc4101 fragment[9]. Results reported here point out additional applications. Vectors that contain *ars*1 (which we shall call 'YR vectors') can be maintained in yeast cells in two easily distinguishable states. Although autonomously replicating in selective conditions, YR transformants are mitotically unstable. In this state, the supercoiled YR DNA can be easily re-isolated (D.T.S., K.S. and M. Thomas, unpublished observations). In addition, stable transformants with integrated YR sequences can then be easily obtained at high frequency. In this second state, the location of the integrated DNA can be determined physically (ref. 9 and above) or by simple genetic analysis (see ref. 11). Such linkage analysis could determine the chromosomal location of a yeast DNA fragment that had been cloned in a YR vector. Integrated YR vectors can also be used for directed genetic manipulation, wherein a sequence is replaced by an altered but homologous counterpart through an integration–excision mechanism[9,12].

In addition to its uses as a vehicle for clonally isolating DNA in yeast, YRp7 will facilitate studies of yeast DNA replication in several ways. First, continuation of the preliminary genetic analysis described here will determine the sequences essential for the functioning of a eukaryotic chromosomal replicator. Second, other functions that control *ars*1 replication may be identifiable by genetic or biochemical techniques; for example, several mutants that are temperature-sensitive for the initiation of DNA synthesis have been characterised[24]; their effects on *ars*1 replication could be studied in detail. Third, the supercoiled YRp7 plasmid could be used (either with or without its chromatin protein complement) as a template for *in vitro* DNA replication systems.

The high frequency of transformation associated with *ars*1 suggests an easy method for the isolation of other chromosomal replicators. Random fragments of DNA can be inserted into a yeast vector that transforms only at low efficiency. Transformation of a yeast strain by the hybrid molecules will result in an enrichment for those fragments which allow autonomous replication. Studies of such *ars* loci isolated from yeast and other organisms are in progress.

The characterisation of a chromosomal replicator represents the first step towards the goal of constructing an operational eukaryotic chromosome. The isolation of other elements that control replication and proper segregation will not only elucidate the mechanisms of chromosome function but will provide the means for determining how chromosome structure affects gene expression.

Ca^{2+}-sensitive gelation of actin filaments by a new protein factor

Naotoshi Mimura & Akira Asano

Institute for Protein Research, Osaka University, Osaka 565, Japan

Two protein factors which bind to, and induce gelation of, actin filaments were purified from Ehrlich tumour cells. Filamin induced Ca^{2+}-insensitive gelation, whereas a new protein factor ('actinogelin') was found to induce Ca^{2+}-sensitive gelation.

FOR a better understanding of the cellular functions of actin filaments more information on the properties of actin accessory proteins is needed. Actin-related gelation of cell-free extracts prepared from amoebae[1-3], mammalian cells[4-6] and sea urchin eggs[7] provides an excellent system for studies on actin accessory proteins, especially on the regulation of their interaction with actin filaments.

Involvement of Ca^{2+} in the regulation of microfilament function is possible, since intracellular Ca^{2+} at micromolar concentration is known to influence processes such as cell motility[8], chemotaxis[9], secretion[10,11] and fertilisation[12]. Studies on reversible inhibition of actin-related gelation by micromolar concentrations of Ca^{2+} in a large variety of cells[3,6,7-13] further support this hypothesis. Possible involvement of Ca^{2+} in HVJ(Sendai virus)-induced cell fusion[6,14-16], chemically induced cell fusion[17] and fusion of myoblast[18] has also been reported.

Ca^{2+}-insensitivity of filamin(actin binding protein)-dependent gelation

Since filamin (or a protein similar to actin binding protein of Stossel and Hartwig[4]) is concentrated in gels together with actin from Ehrlich tumour cell extracts (Fig. 1*a*, *b*), the role of filamin in Ca^{2+}-sensitive gelation was studied. As shown in Fig. 1*c*, filamin purified from Ehrlich tumour cells by a combination of the methods described for actin binding protein of macrophage[14] and for smooth muscle filamin[19,20], gave a single band by SDS-gel electrophoresis. The gel formed by mixing this protein with skeletal muscle actin consisted of only filamin and actin (Fig. 1*d*). Degree of gelation measured by pelleting of protein by centrifugation at 49,000*g* for 10 min, is dependent on the amount of filamin added but is not appreciably affected by the presence of either Ca^{2+} or EGTA (Fig. 2). Similar insensitivity towards Ca^{2+} in a purified and reconstituted system was recently reported for 'actin binding protein'-dependent gelation of rabbit alveolar macrophage extracts[21] and '57 K dalton and 220 K dalton protein'-dependent gelation of sea urchin egg extracts[22]. As a result, the search for calcium-sensitivity conferring factor(s) is under way in several laboratories[6,23,24].

Purification of a Ca^{2+}-sensitive gelation factor (actinogelin)

During a search for a factor which confers Ca^{2+}-sensitivity on filamin-related gelation of muscle actin, a protein fraction was obtained from Ehrlich cell extracts which, surprisingly, did not contain filamin but did produce gel on mixing with rabbit skeletal muscle actin, provided that 1 mM EGTA is included in the reaction mixture. No requirement for filamin was observed for gelation by this protein factor as described below. As shown in Fig. 3, the degree of gelation assayed by the centrifugation method is proportional to amounts of DE32 eluate fraction added to skeletal muscle actin. Further purification of the protein fraction on hydroxyapatite column showed that a protein, of MW 115,000 on SDS-polyacrylamide gel electrophoresis, was concentrated in an active fraction (fraction b) and the same band was also selectively concentrated with actin in gel fraction pelleted by centrifugation (Fig. 4). In contrast, there was no co-precipitation of such a band with actin from reaction mixtures containing inactive fractions (fractions a and c).

This new gelation factor was purified by the method outlined below until the product gave a single band on SDS-gel electrophoresis (Fig. 1*e*) (see legends to Figs 1 and 4 for details). Cell-free extracts were obtained by the method described previously[6] except that Tris-maleate buffer was replaced with 20 mM imidazole-HCl buffer (*p*H 7.0). After adjusting KCl concentration of the extract to 0.6 M, the extract (190 ml, about 5,700 mg protein) was fractionated by ammonium sulphate precipitation (between 15% and 35% saturation). One unit is defined as the amount of gelation factor which precipitates 1 mg of actin in a Ca^{2+}-sensitive process on centrifugation at 49,000*g* for 10 min (control experiments in which the same actin preparation was centrifuged in the same medium were performed, and the value obtained was subtracted from the experimental values). The same ammonium sulphate fractionation cycle was repeated, and the resultant fraction was dialysed and then clarified by centrifugation. The supernatant (630 mg protein, 189 U) was applied on DE32 column, and an active fraction was eluted with 0.4 KCl (77 mg protein, 215 U). Further purification was achieved by hydroxyapatite column chromatography and the active fraction (16 mg protein, 110 U) was applied on and eluted from Sepharose 6B column. On electrophoresis, about one-third of the fractions obtained (2.5 mg protein, 24 U) were judged pure (Fig. 1*e*). For higher recovery, fractions containing appreciable activity were pooled (6.2 mg protein, 57 U), and some of this was further purified by chromatography on DE32. Since filamin interferes with the assay, in crude preparations the factor cannot be determined accurately. However, a purification of ~30-fold was achieved with 30% recovery from the second ammonium sulphate fractionation step to Sepharose 6B gel filtration step. From the final yield of the protein (about 0.1% of crude extract), the content of the Ca^{2+}-sensitive gelation factor in crude extracts is calculated to be >0.3%. This protein is tentatively named as 'actinogelin' to avoid confusion with the other actin binding proteins. Gel reconstituted from skeletal muscle actin and actinogelin was found to be composed of actinogelin and actin (Fig. 1*f*).

Thus two gelation systems which differ in sensitivity towards micromolar concentrations of Ca^{2+} could be reconstituted from skeletal muscle actin and protein fractions which were purified from the same cell-free extracts. To establish whether these fractions can be detected in crude systems, SDS-gel electrophoretograms of crude cell-free extracts in the presence and absence of EGTA were compared (Fig. 1*a*, *b*). Bands corresponding to filamin, actinogelin and actin were concentrated in the gel. 'Actinogelin' and 'filamin' are confirmed by co-electrophoresis of the gel fraction with purified proteins. Protein bands of similar electrophoretic mobility (MW ~100,000–120,000 K) can be detected in published electrophoretograms of crude gel fractions of HeLa cells[25], leukocyte extracts[26] and amphibian cell extracts[13], although they were not mentioned in the texts. Thus it seems possible that two different gelation factors might co-exist in several cells other than Ehrlich tumour cells.

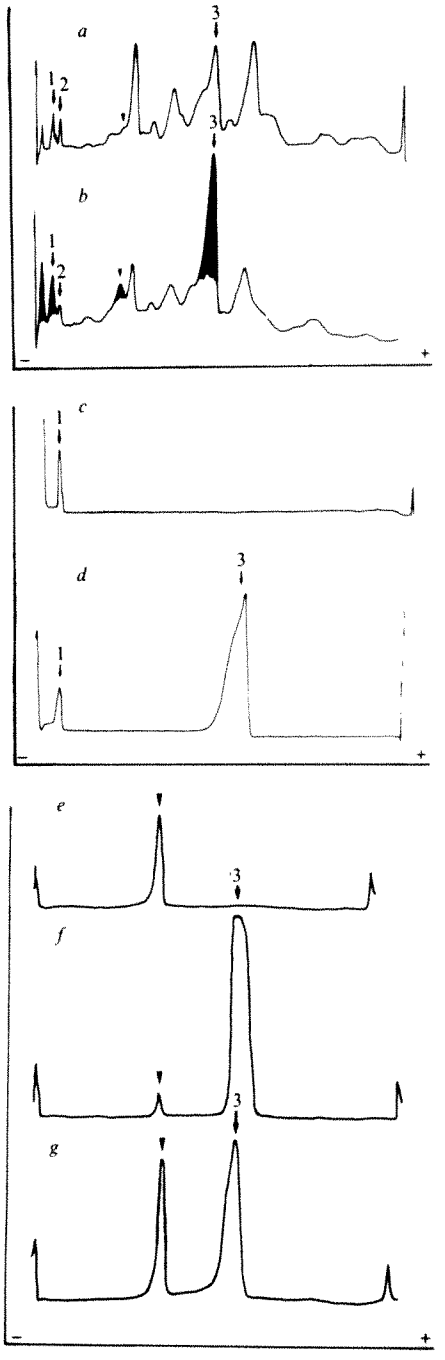

Fig. 1 SDS-polyacrylamide gel electrophoretograms of crude and purified gelation factors and gels. *a*, Crude extract; *b*, gel formed from crude extract, protein bands which were concentrated in the gel compared to the extract are shown in black. *c*, Filamin purified from Ehrlich tumour cells as described in Fig. 2 legend. *d*, Gel formed by reconstitution of 340 μg actin and 20 μg of filamin. *e*, Purified actinogelin (Sepharose 6B fraction), 10 μg. *f*, Gel formed by reconstitution of 352 μg actin and 21 μg of pure actinogelin and centrifuged at 49,000*g* for 10 min. The amount of total protein applied to the gel column was 30 μg. *g*, Precipitate formed by reconstitution of 40 μg actin and 40 μg of pure actinogelin, followed by centrifugation at 140,000*g* for 3 h. Amount of total protein applied to the gel column was 30 μg. Pure actinogelin was obtained by Sepharose 6B column chromatography of the hydroxyapatite eluate fraction. The pooled fraction obtained as described in Fig. 4 legend was concentrated to 1.0–1.5 ml and applied to a column of Sepharose 6B (1.2×95 cm) equilibrated with 20 mM Tris-HCl (*p*H 7.6) containing 50 mM sodium chloride, 0.1 μg ml^{-1} pepstatin and 1 mM sodium azide. Elution was carried out by the same buffer and 1.2-ml samples were collected. Actinogelin was eluted from the column as a major peak with some tailing material(s). The main fractions whose purity was checked by SDS-polyacrylamide gel electrophoresis and found to be homogeneous were pooled and used as pure actinogelin preparation. Bands 1, 2 and 3 correspond to filamin, myosin heavy chain and actin, respectively. Actinogelin is marked by an arrowhead. Acrylamide at 5.6% was used.

Characteristics of actinogelin-dependent gelation

The effects of free Ca^{2+} on the extent of gelation in the actinogelin-dependent system were almost identical to the effects in crude extracts—gelation was inhibited by micromolar concentrations of free Ca^{2+} (Fig. 5). Furthermore, rapid solation of the formed gel by increasing free Ca^{2+} occurred at similar Ca^{2+} concentrations in the two systems[6]. Gelation activity of purified actinogelin is similar to or higher than that of pure filamin in Ehrlich tumour cells on weight basis. Since the MW of native actinogelin is not yet known, we cannot calculate specific gelation activity. But a molar ratio of ~1 : 100 of either filamin or actinogelin (calculated as dimer) could induce detectable gelation of skeletal muscle actin.

The maximum ratio of binding of actinogelin to F-actin was estimated for a fixed amount of actin in the system (40 μg in 80 μl), with increasing amounts of actinogelin added to it, and by applying centrifugation at 140,000*g* for 3 h to precipitate F-actin. Resultant pellets were analysed by SDS-gel electrophoresis (Fig. 1*g*). A linear increase of actinogelin recovered in the pellet fractions was observed at up to 20 μg actinogelin per tube, but no further increase was detected when the actinogelin level was raised to 40 μg: no appreciable actinogelin (0–3 μg) was found in the supernatant fraction when up to 20 μg actinogelin was present in the system, whereas at 40 μg about 21 μg of the added actinogelin was recovered in the supernatant. Thus it is unlikely that the preparation is contaminated with protein which lacks actin binding ability. No measurable precipitation of actinogelin was observed in control experiments without actin. Assuming that actinogelin is mainly present as the dimer (preliminary observation), we estimate the molecular ratio of actin to actinogelin at maximum binding to be ~10–12.

Possible participation of Ca^{2+}-activated protease in Ca^{2+} inhibition of gelation[27] was checked by measuring the reversibility of the inhibition. Gelation mixture containing actinogelin and actin was preincubated in the presence of 50 μM Ca^{2+} for 60 min at 20 °C, and EGTA was added to a final concentration of 400 μM to decrease the free Ca^{2+} concentration. The degree of gelation of the treated system was identical with that of unpreincubated control. Thus, irreversible destruction of reaction components by a Ca^{2+}-activated protease could be excluded. The effect of Ca^{2+} on G to F transformation of skeletal muscle actin was measured by determining the amounts of F-actin pelleted at 140,000*g* for 3 h. No appreciable difference in the amounts of F-actin pelleted was observed between centrifugations performed in the presence or absence of Ca^{2+} in the experimental conditions used.

The possibility that small MW Ca^{2+}-binding protein similar to Ca^{2+}-dependent modulator protein[28,29] of non-muscle cells or leiotonin C of smooth muscle[30] might be present in actinogelin preparations and cause Ca^{2+}-sensitivity seems unlikely for the following reasons: (1) An actinogelin preparation purified to the Sepharose 6B step was passed through a Sephacryl S-200 column equilibrated with a medium containing 1 mM EGTA and 0.8 M KCl to facilitate dissociation of any Ca^{2+}-modulator protein that may have been present. But, no decrease in gelation activity and Ca^{2+}-sensitivity of the actinogelin preparation was observed after such treatment. (2) An actinogelin preparation was rechromatographed on DE32 in a medium containing 1 mM EDTA which was used for separation of acidic leiotonin C from leiotonin A[30], but no evidence for separation of highly acidic protein from actinogelin was obtained.

Semiquantitative densitometry of SDS-gel electrophoretograms of gel pellets showed actinogelin recover in the pellet fraction decreased in the presence of 50 μM Ca^{2+} to less than one-third of that of control with 0.5 mM EGTA. Whether this decreased binding of actinogelin to F-actin is sufficient to explain inhibition of gelation by Ca^{2+}, or whether a change in oligomeric structure such as a dimer to monomer conversion induced by Ca^{2+} must be introduced to explain the inhibition is not yet clear.

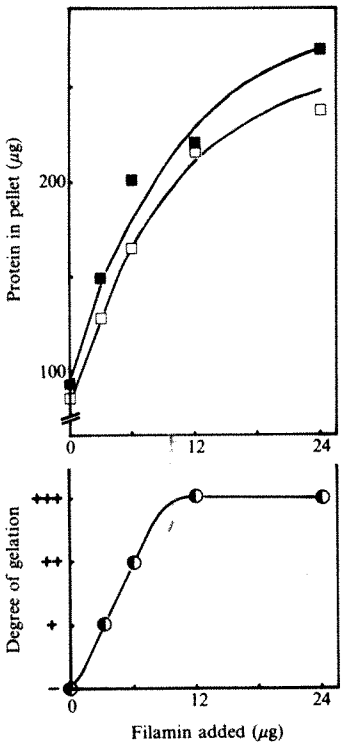

Fig. 2 Effects of Ca^{2+} on filamin (actin binding protein)-induced gelation of rabbit skeletal muscle actin. Reaction medium consisted of 10 mM imidazole-HCl buffer (*p*H 7.2), 50 mM potassium chloride, 1 mM magnesium chloride, 2.0 mg ml^{-1} of rabbit skeletal muscle actin containing ATP at a final concentration of 65 μM, and either 1.15×10^{-4} M $CaCl_2$ (■) or 5×10^{-4} M EGTA and 6.5×10^{-5} M $CaCl_2$ (□). Filamin was purified from Ehrlich tumour cells as follows. Cells resuspended in two volumes of an extraction medium containing 0.34 M sucrose, 1 mM ATP, 1 mM EGTA, 1 mM dithiothreitol, 0.1 mM phenylmethylsulphonylfluoride (PMSF), 0.1 μg ml^{-1} pepstatin, and 20 mM imidazole-HCl (*p*H 7.0 at 25 °C), were disrupted by a cell disruption bomb (Purr) as described previously[6]. The disrupted cells were centrifuged at 30,000 r.p.m. for 1.5 h in a Hitachi 55P ultracentrifuge with a RP30 rotor at 2° to 4 °C and the resultant clear supernatant was collected. As the first step, filamin was extracted from gel. After addition of 1 mM $MgCl_2$, the cell extracts were warmed to 25 °C for 1 h and then resultant gels were sedimented at 40,000*g* for 10 min in a Sorvall SS-34 rotor. The pellets were washed twice with 0.1 M KCl in 20 mM imidazole-HCl (*p*H 7.0) and resuspended in one-fifth of the original volume of a medium containing 0.6 M KCl, 1 mM EDTA, 1 mM dithiothreitol, 0.1 mM PMSF, 0.1 μg ml^{-1} pepstatin and 10 mM imidazole-HCl (*p*H 7.0). The suspension was left to stand in a cold room (4 °C) with stirring overnight to release filamin from insoluble materials. Insoluble materials containing F-actin were removed by centrifugation at 100,000*g* for 3 h at 4 °C. The supernatant was collected and subjected to the second step of purification. Saturated ammonium sulphate solution with *p*H adjusted to 7.0 was added to the supernatant to give 15% saturation. After removing the resultant precipitate, the supernatant was brought to 35% saturation by adding saturated ammonium sulphate solution. The pellet was collected and suspended in 0.6 M KI solution (containing 0.6 M KI, 20 mM $Na_2S_2O_3$, 1 mM EDTA, 1 mM dithiothreitol, 0.1 mM PMSF, 0.1 μg ml^{-1} pepstatin, 10 mM imidazole-HCl *p*H 7.0). The ammonium sulphate fractionation (15–35% saturation) was repeated, and the pellet was suspended in 1–2 ml of the 0.6 M KI solution. After standing for 30 min at 4 °C, the suspension was applied to a 1.6×83 cm column of Sepharose 4B equilibrated with a low ionic strength buffer (2 mM Tris-HCl, 0.2 mM ATP, 0.2 mM $CaCl_2$, 0.5 mM 2-mercaptoethanol, *p*H adjusted to 8.0), and eluted with the same buffer at a flow rate of 6 ml h^{-1}. Filamin was eluted as a major peak. Peak fractions were checked for purity by SDS-polyacrylamide gel electrophoresis, and fractions found to be homogeneous were pooled and used as pure filamin. If necessary, fractions with slight contamination were further purified by DEAE-cellulose (Whatman DE32) column chromatography. Filamin was eluted from the DE32 column by stepwise elution between 0.1 M and 0.15 M KCl dissolved in 20 mM Tris-HCl buffer (*p*H 7.6). Purified filamin was added to the gelation system as indicated to a final volume of 0.2 ml. Incubation was for 60 min at 20 °C. The degree of gelation was assessed by tilting tubes containing gels as described previously[6], either in the presence of Ca^{2+} or EGTA (◐). Gelation was quantitated by measuring amounts of protein pelleted by centrifugation at 49,000*g* for 10 min at 15 °C. Pellets were rinsed once by the reaction medium, then the amounts of protein were measured by the method used for the precipitate[43].

The role of actinogelin and filamin in gelation of crude extracts

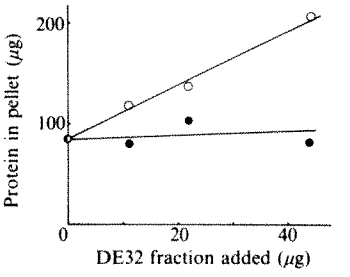
Since at least two different gelation systems were found in Ehrlich tumour cell extracts, the relationship between these systems was studied. In the presence of a sub-optimum concentration of actinogelin and various amounts of filamin together with actin, gel formation is partially sensitive to Ca^{2+} at low concentrations of filamin. The extent of gelation is partially additive when EGTA is present in the medium, whereas in the presence of 50 μM Ca^{2+} it is almost identical with that of filamin alone. At higher concentrations of filamin, however, gelation becomes insensitive to Ca^{2+} (Fig. 6). Thus, the involvement of actinogelin in determining Ca^{2+}-sensitivity of the crude system cannot be unequivocally established until a quantitative determination can be made. But, quantitation of filamin and actinogelin in crude extracts is rather difficult, and effects of the other proteins which bind to actin, such as myosin and tropomyosin, on interaction of any of the gelation factors cannot be excluded. For example, heavy meromyosin inhibits sedimentability of filamin without appreciably affecting that of actin[25], and filamin was found to inhibit actin activation of heavy meromyosin ATPase[31]. Furthermore, the possible role of other regulatory systems has to be considered. Some of the studies on gelation of crude cell-free extracts which may shed light on this problem are discussed below.

Gelation of some ascites tumour cell extracts is enhanced by tryptic digestion of the extracts. Close examination of the resultant gel from the treated sample revealed that no filamin-like component is concentrated in the gel, whereas that obtained from untreated control contained a filamin-like component[32]. Although Ca^{2+}-sensitivity was not tested (EGTA was included in the reaction mixture), this result suggests the presence of a gelation factor which is different from filamin. On the other hand, Brotshi *et al.*[21] surveyed gelation factors of rabbit alveolar macrophage extracts and found that the main component of gelation of the extracts is high MW 'actin binding protein'. But, as they did not include Ca^{2+} chelators in the reaction medium, no Ca^{2+}-sensitive gelation factor would have been detected.

Thus actinogelin appears to play an important part in the Ca^{2+}-sensitive gelation of the crude extract of Ehrlich tumour cells for the following reasons: (1) In crude extracts actinogelin becomes concentrated in the gel; (2) the concentrations of Ca^{2+} required for inhibition of gelation are almost identical in crude and reconstituted systems; (3) no other fractions from the crude extract would either induce Ca^{2+}-sensitive gelation or confer Ca^{2+}-sensitivity to filamin-dependent systems; (4) the amounts of actinogelin recovered in the purified fraction were sufficient to explain gelation of the crude extracts.

Comparison of actinogelin with the other actin-accessory proteins

There are several proteins which bind to either actin filaments or monomeric actin in animal cells. Those which bind to filamentous actin and cross-link between actin filaments could form actin-related gels. Filamin (actin binding protein) can form



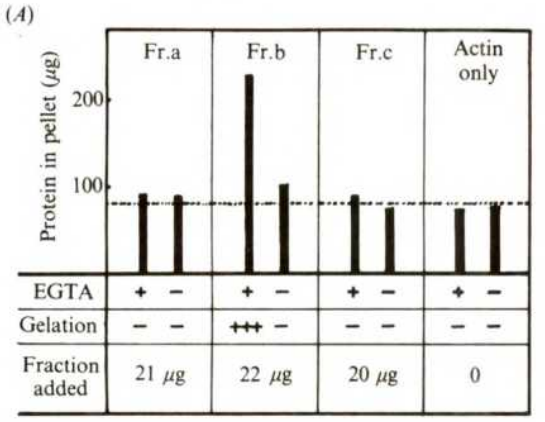


Fig. 3 Reconstitution of Ca^{2+}-sensitive gelation with rabbit skeletal muscle actin and a crude fraction partially purified from Ehrlich tumour cell extracts by DE32 chromatography. ○, In the presence of 1 mM EGTA and 9×10^{-5} M $CaCl_2$; ●, with 9×10^{-5} M $CaCl_2$ added.

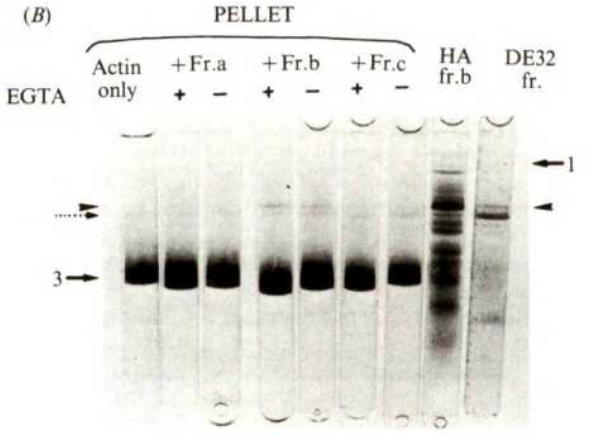

Fig. 4 Purification of actinogelin by hydroxyapatite chromatography. Actinogelin was purified to DE32 step as follows: Cell-free extracts were prepared as described in Fig. 2 legend. After adjusting KCl concentration of the extract to 0.6 M, the extract was fractionated by ammonium sulphate (between 15% and 35% saturation). The resultant pellet was dispersed with a buffer containing 10 mM imidazole-HCl (*p*H 7.0), 0.1 mM KCl, 2 mM $MgCl_2$, 0.1 mM PMSF and 0.1 μg ml^{-1} pepstatin and then dialysed overnight against the same buffer. The dialysed solution was adjusted to a final concentration of KCl of 0.6 M, and was spun at 100,000*g* for 3 h, and clear supernatant was fractionated again by ammonium sulphate between 15% and 35% saturation. The resultant pellet was dispersed with a buffer containing 20 mM imidazole-HCl (*p*H 7.2), 0.1 mM PMSF and 0.1 μg ml^{-1} pepstatin and then dialysed overnight against the same buffer. Insoluble materials were removed by centrifugation at 40,000*g* for 10 min in a Sorvall SS-34 rotor and the clear supernatant was applied to a 3 × 15 cm column of DE32 which was equilibrated with 20 mM imidazole-HCl buffer (*p*H 7.2). The column was washed with 100 ml of 20 mM imidazole buffer and subsequently washed with 400 ml of 20 mM imidazole buffer containing 0.2 M KCl, and then actinogelin was eluted with 400 ml of 0.4 M KCl in 20 mM imidazole buffer. The fractions eluted with 0.4 M KCl were dialysed against 10 mM potassium phosphate (*p*H 6.8) and applied to a 2 × 6.5 cm column of hydroxyapatite. After washing the column with 70 ml of 50 mM potassium phosphate (*p*H 6.8), elution was carried out with a linear gradient prepared with 60 ml of 50 mM potassium phosphate and 60 ml of 0.25 M potassium phosphate (*p*H 6.8) at a flow rate of 10 to 12 ml h^{-1}. Actinogelin was eluted as a major peak between 0.1 and 0.2 M potassium phosphate. Fractions with an appreciable actinogelin content on SDS-polyacrylamide gel electrophoresis were pooled as fraction b. Fractions just preceding the actinogelin peak were collected as fraction a, and those following the fraction b were used as fraction c. *a*, The gelation activity of the three fractions designated a, b and c was measured as described in Fig. 2 legend. Only fraction b has the ability to reconstitute Ca^{2+}-sensitive gelation. *b*, Electrophoretograms of purified fractions and gels. Although several protein bands are concentrated in fraction b compared with DE32 fraction, only a protein band (actinogelin) marked by an arrowhead (►) is bound to actin. The band marked no. 3 is actin and the band marked by a dotted arrow is a contaminant of this particular actin preparation. The arrow marked no. 1 shows the migration position of filamin in the conditions used. The amounts of total protein applied to each acrylamide gel column were 25, 46, 42, 43, 42, 31, 31, and 13 μg, respectively from left to right. Acrylamide gel at 5.6% was used.

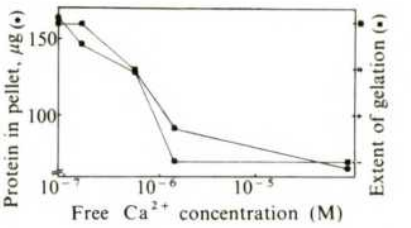

Fig. 5 Effect of free Ca^{2+} concentrations on the extent of gelation of a reconstituted system consisted of skeletal muscle actin and actinogelin. Reaction conditions were similar to those described for Fig. 2, except that 472 μg of actin and 150 μg of crude actinogelin (DE32 fraction) were used. Free Ca^{2+} concentrations were manipulated by an EGTA-Ca^{2+} buffer system[43] as described previously[6].

Ca^{2+}-insensitive gels as described above, α-actinin and tropomyosin have been shown to bind to actin cables by a fluorescence technique[33], and α-actinin produced gel when added to F-actin[34,35], although this gelation was not sensitive to Ca^{2+} (K. Maruyama, personal communication). Mixing of F-actin with tropomyosin and troponin also produced transient gelation, but this gelation was not inhibited by Ca^{2+}, although reformation of gel from high temperature-dissociated samples was inhibited by Ca^{2+} (ref. 36). The other characteristics of troponin-related gelation[37] are quite different from those of actinogelin-related gelation described in this article, and there is no evidence for the presence of troponin in non-muscle cells[38]. Kane's 58,000 MW protein isolated from sea urchin eggs is required for actin bundle formation, and interestingly, there is another protein (MW 220,000) which binds to actin–58,000 MW protein 'bundles' and is required for gel formation in sea urchin eggs[22]. No Ca^{2+}-sensitivity was found in this reconstituted system, although crude extracts of sea urchin eggs formed a Ca^{2+}-sensitive gel[7]. Lower MW proteins (gelactins) have been implicated in actin-related gelation of *Acanthamoeba castellanii* extracts[2]. Ca^{2+} or Mg^{2+} is required for this type of gelation. Condeelis and Taylor[3] have reported Ca^{2+}-sensitive gelation of cell-free extract of *Dictyostelium discoideum*, and purification of gelation factor(s) is under way[24]. It was found recently that microtubule associated proteins interact with actin filaments, although binding force between these proteins is rather weak, in other words, no co-precipitation of microtubule associated proteins with F-actin could be observed[39].

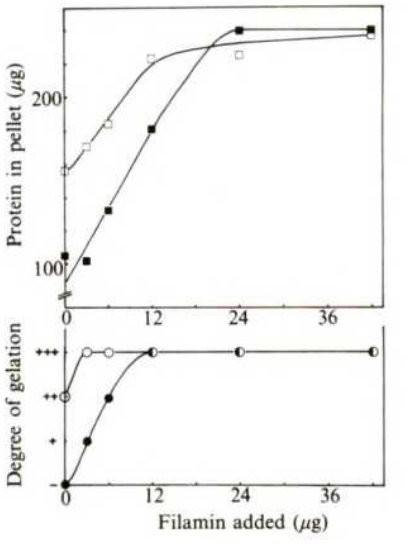

Fig. 6 Ca^{2+}-sensitivity of gelation reconstituted from skeletal muscle actin, actinogelin and filamin. Reaction conditions were similar to those described for Fig. 1, except that 400 μg of actin, 13.6 μg of actinogelin (hydroxyapatite fraction b) and the indicated amounts of filamin were used. □, ○, Experiments in the presence of 0.5 mM EGTA and 65 μM $CaCl_2$: ■, ●, in the presence of 115 μM $CaCl_2$.

Binding of a large amount of F-actin to clathrin (major protein of coated vesicles) was reported recently[40], but no effect of Ca^{2+} on this interaction is known. Thus, none of the gelation-inducing proteins reported previously has been identified as a Ca^{2+}-sensitive gelation factor, with the possible exception of a protein fraction reported in an abstract[23] which confers Ca^{2+}-sensitivity on actin binding protein-dependent gelation. The relationship between this protein and actinogelin is not yet clear, as a detailed report on Ca^{2+}-sensitivity conferring protein is not yet available. One difference is obvious, however—actinogelin alone may form a gel by interaction with F-actin, but the macrophage factor requires actin binding protein for gelation[23].

Micromolar concentrations of Ca^{2+} seem to exert at least two different effects on microfilament-dependent functions[38]; one is the well established effect of Ca^{2+} on actomyosin ATPase and superprecipitation of actomyosin[38,41] and the importance of this type of regulation is well known. The possible importance of Ca^{2+}-regulation of actin-to-actin (or actin-to-actin binding proteins) interaction has received less attention. But, as is reported or quoted here, Ca^{2+} definitely affects actin-to-actin interaction reversibly at concentrations similar to those which activate actomyosin ATPase. And, the distribution of actin is known to change extensively in several cellular functions, such as virus-induced transformation, in non-muscle cells. Thus, those two types of regulation seem to be equally important in non-muscle cells.

We thank Professors Ryo Sato, Y. Tonomura and K. Maruyama for helpful discussions. This work was supported in part by Cancer Research grants and a grant-in-aid for Special Project Research on Biomembrane from the Ministry of Education, Science and Culture of Japan, and the Naito Memorial Foundation for Promotion of Science.

Universal microwave radiation and extragalactic γ radiation

W. Niemann & K. O. Thielheim

Institut für Reine und Angewandte Kernphysik, Universität Kiel, FRG

The detection of an extragalactic component of celestial γ-radiation[1,2] has stimulated the question of the possible contributions from external point sources, especially since the detection of γ rays from NGC4151 (ref. 3) and from 3C273 (ref. 4). Here we discuss the role of the inverse Compton effect (ICE) of relativistic electrons on universal microwave photons for the production of high energy γ rays from normal spiral galaxies.

It was estimated[5,6] from the total galactic γ-ray luminosity of our Galaxy that the possible contribution from normal spiral galaxies to extragalactic γ radiation is between 4 and 100% of the total for energies >100 MeV, 100% being reached if evolutionary effects within the involved spiral galaxies are taken into account[6]. The resulting flux from all involved external objects in the framework of a Friedman world model is given by[6,7]

$$I(E_\gamma) \propto H_0^{-1} \cdot \int_0^{z_0} \mathrm{d}z\, Q_g[(1+z)\cdot E_\gamma, z] \cdot (1+\Omega\cdot z)^{-1/2} \cdot (1+z)^{-1} \quad (1)$$

where H_0 is the Hubble constant, Ω is the density parameter and $Q_g(E'_\gamma, z)$ is the total γ-ray emission of one object within the ranges of energy $E'_\gamma, E'_\gamma + \mathrm{d}E'_\gamma$ and redshifts $z, z+\mathrm{d}z$, which in this calculation is restricted to γ photons from normal spiral galaxies. To simplify the estimation of this contribution all normal spirals are assumed to be of the same age, t_g^0, which is related to the value of z_0 up to which the redshift z has to be integrated by $t_g^0 = t_g(z=0)$, where the time scale is related to the scale of redshifts by

$$t_g = H_0^{-1} \cdot \int_z^{z_0} \mathrm{d}z'\,(1+z')^{-2} \cdot (1+\Omega\cdot z')^{-1/2} \quad (2)$$

Here we compare the contribution of the ICE of relativistic electrons on universal microwave photons for the production of high-energy γ rays with those from other electromagnetic processes such as bremsstrahlung of relativistic electrons. To simplify the calculations we assume that the mean γ-ray emission of spiral galaxies has a diffuse origin and that the physical parameters which are relevant to these processes are equal to those in our Galaxy and do not change as these galaxies evolve,

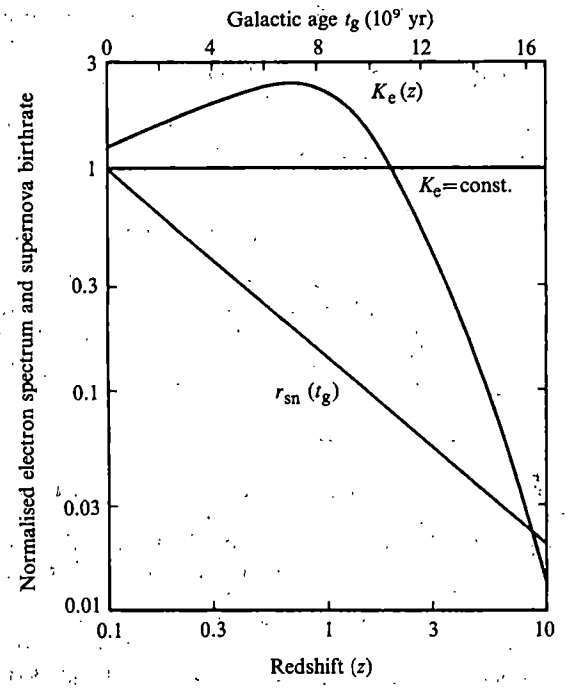

Fig. 1 Normalised supernovae birthrate $r_{SN}(t_g)$ (from ref. 10) and normalised electron spectrum $K_e(z)$ of high-energy electrons for the case of time-dependent electron sources and losses and for the case of constant galactic parameters. $\Omega = 0.08$; $H_0 = 60$ km s^{-1} Mpc^{-1}.

except for the production rate of relativistic electrons which is believed to be associated with the birthrate of supernovae or pulsars, and with the cosmological evolution of the energy distribution and temperature T of the universal microwave radiation. Consequently, the cosmological change of the electron spectrum must also be considered. At present it is not possible to investigate this problem in more detail.

The two aforementioned processes are essentially influenced by the differential energy spectrum of relativistic electrons. As we wish to consider γ rays in the energy range around 100 MeV, for bremsstrahlung the corresponding electron energies are around 200 MeV and for ICE on microwaves around 200 GeV. In these two energy ranges the electron spectrum in our Galaxy is of the form

$$I(E) \propto E^{-p} \tag{3}$$

with two different values of p (refs 8, 9). The resulting differential source functions of γ photons from electron bremsstrahlung and ICE on microwaves are

$$Q_{br}(E_\gamma) \propto E_\gamma^{-p_1} \tag{4}$$

and

$$Q_{MW}(E_\gamma) \propto E_\gamma^{-(p_2+1)/2} \cdot T^{(p_2+5)/2} \tag{5}$$

respectively, with different values of p_1 and p_2. The ratio of these two source functions in our Galaxy at $E_\gamma = 100$ MeV has been estimated as

$$r = Q_{br}(100\,\text{MeV}) : Q_{MW}(100\,\text{MeV}) \approx 40:1 \tag{6}$$

which has comparatively large uncertainties.

The temperature of the universal microwave radiation varies as $T(z) = T_0 \cdot (1+z)$ with $T_0 = 2.7$ K; the corresponding photon energy density is $w_{phot}(z) = w_{phot}(0) \cdot (1+z)^4$. Therefore this increase of temperature would be expected to increase the production of γ rays due to ICE on microwaves with increasing redshift according to equation (5). The sources of the electrons may be supernovae or pulsars with a spectrum

$$q(E, t_g) = \bar{K} \cdot E^{-s} \cdot r_{SN}(t_g)$$

where $r_{SN}(t_g)$ is the supernovae birthrate, normalised to $r_{SN}(t_g^0) = 1$. Models on galactic evolution[10] suggest that

$$r_{SN}(t_g) \propto \exp\{-t_g/t_c\} \tag{8}$$

with the characteristic time t_c of the order of 4×10^9 yr. The increase of w_{phot} with increasing redshift leads to increasing energy losses $\dot{E} \propto w_{phot} \cdot E^2$ which changes the equilibrium electron spectrum. Taking into account that the electron lifetime in our Galaxy is of the order of 10^7 yr, the time scale of the change of the supernovae birthrate is large compared with the time scale of electron diffusion. The change of the electron spectrum is thus determined by a continuity equation for the differential number density of electrons, $N(E, t_g)$, in which energy losses and leakage are balanced by a source term

$$\frac{\partial}{\partial E}(\dot{E} \cdot N(E, t_g)) + \frac{N(E, t_g)}{\tau} = \bar{K} \cdot E^{-s} \cdot r_{SN}(t_g) \tag{9}$$

with the time appearing as a parameter. At electron energies around 200 GeV which are essential for the ICE on microwaves, energy losses are dominated by synchrotron emission and inverse Compton scattering which are $\propto E^2$. Thus

$$\dot{E}(E, z) = \{c_1 + c_2 \cdot (1+z)^4\} \cdot E^2 = a(z) \cdot E^2 \tag{10}$$

The solution of equation (9) with respect to equations (8) and (10) expressed in terms of redshift, z, is

$$N(E, z) \propto f(E, z) \cdot E^{-2} \cdot \int_E^\infty \mathrm{d}\mathbf{E} \cdot \mathbf{E}^{-s} \cdot \exp\{+1/\tau \cdot a(z)\mathbf{E}\} \tag{11}$$

with

$$f(E, z) = r_{SN}(t_g(z)) \cdot a^{-1}(z) \cdot \exp\{-1/\tau \cdot a(z) \cdot E\} \tag{12}$$

At high energies this expression reduces to

$$N(E, z) = K_e(z) \cdot E^{-(s+1)} \tag{13}$$

where $K_e(z)$ is given by $\bar{K} \cdot r_{SN}(t_g(z)) \cdot a^{-1}(z) \cdot (s-1)^{-1}$. $\bar{K}$ and s are adjusted to experimental data[9] at $z = 0$. Figure 1 shows the evolution of K_e for the case of z-variable energy losses and supernovae births in comparison to the local value which is normalised to unity. Also shown is the normalised supernovae birthrate as a function of galactic age (taken from ref. 10). For the 200-MeV electrons, the main energy losses are due to ionisation and bremsstrahlung[11], so the increase of the photon energy density of the microwaves has negligible influence on these electrons. To compare the contributions to extragalactic γ radiation by the two abovementioned processes, equations (4) and (5) are inserted into equation (1) to give

$$I_{br}(E_\gamma) \propto H_0^{-1} \int_0^{z_0} \mathrm{d}z \cdot K_e'(z) \cdot E_\gamma^{-p_1} \cdot (1+z)^{-(p_1+1)} \cdot (1+\Omega z)^{-1/2} \tag{14}$$

$$I_{MW}(E_\gamma) \propto H_0^{-1} \int_0^{z_0} \mathrm{d}z\, K_e(z) \cdot E_\gamma^{-(p_2+1)/2} \cdot T_0^{(p_2+5)/2} \cdot (1+z) \cdot (1+\Omega z)^{-1/2} \tag{15}$$

The evaluation of the integrals (14) and (15) can be made for three different models. H_0 is adopted to be 60 km s^{-1} Mpc^{-1}, and Ω is taken as 0.08. The actual age t_g^0 of normal spiral galaxies and the corresponding value z_0 of redshift are not well known and need not correspond to the present observational limit of $z_{max} \sim 3.5$ for quasars. Therefore, even higher values can also be used.

Model A: both the equilibrium galactic electron spectrum and the electron sources are considered to be constant during the whole integration period. In this case the contribution of ICE on microwaves (curve A_2 in Fig. 2) overtakes the bremsstrahlung contribution (curve A_1) at a redshift of $z \sim 5$. Consequently, the major part of extragalactic γ radiation from spiral galaxies would be due to the ICE on microwaves at high redshifts.

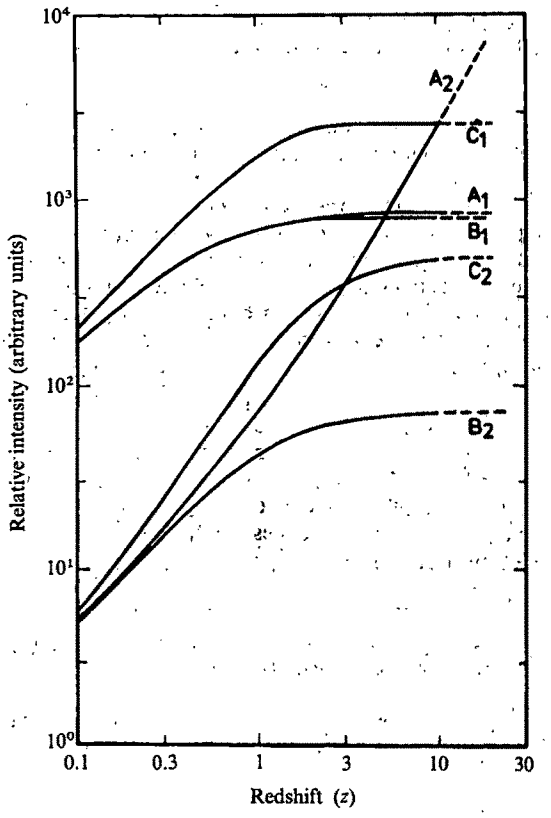

Fig. 2 Relative contributions of electron bremsstrahlung (index 1) and inverse Compton effect (index 2) from normal spiral galaxies to extragalactic γ radiation for the three evolution models A, B and C. $\Omega = 0.08$; $H_0 = 60$ km s^{-1} Mpc^{-1}; $E_\gamma = 100$ MeV.

Model B: the equilibrium electron spectrum at high energies is assumed to be dominated by energy losses $E \propto E^2$; the electron sources are still considered to remain constant. The resulting curves are B_1 and B_2. The bremsstrahlung contribution changes to a very small degree in comparison with A_1, but the ICE contribution is much lower than in model A. It shows a considerable flattening at high redshifts with a ratio $r_B = 11:1$.

Model C: electron sources as well as the equilibrium electron spectrum are assumed to be variable with galactic age. In this case the relative contributions by both processes (indicated by C_1 and C_2 in Fig. 2) increase in comparison with model B; a flattening of the curves is observed for redshifts greater than 4. Here the ratio of the contributions from the two processes at high redshifts is $r_C = 5.5:1$.

We conclude, therefore, that the contribution of γ photons from ICE on microwaves to extragalactic γ radiation is possibly more important than from local effects in our Galaxy; final results strongly depend on the evolution of the involved electron spectrum. In the case of no or weak evolution of the electron spectrum γ rays produced by ICE on microwaves can provide a considerable fraction of extragalactic γ radiation from spiral galaxies. Furthermore, the total galactic spectrum seems steeper at high redshifts than it is locally. These results depend on the choice of the cosmological parameters; if larger values for Ω are used, the integrals (14) and (15) change to a small degree.

Is there a ring around the Sun?

K. Brecher*, A. Brecher†, P. Morrison‡, & I. Wasserman§

More than 300 years after the discovery of Saturn's rings, material rings or ring systems have been found in rapid succession around two of the major planets, Uranus[1] and Jupiter[2]. With rings now known to exist around three of the four major planets, it is natural to assume that they also exist around Neptune. But what about the major object in the Solar System? Is the Sun itself surrounded by a ring of material? Although the planetary system already forms such a 'ring' system, what we have in mind here is the distinct possibility of a ring of rocky material lying no more than a few solar radii from the Sun, by analogy with the spatial configuration of the three planetary ring systems now known. We summarise here the evolutionary, physical, chemical and observational astronomical constraints that can be placed on such a hypothetical ring.

Models of planetary evolution in the early solar nebula give few definite clues pointing to the mass, orbital radius or size distribution of possible objects within the orbit of Mercury. In the absence of any reliable theoretical prediction, one can use the 'Titius–Bode Law' of planetary distances as an indicator of the orbital radius of a planet (or asteroid belt). Although there are several specific functional forms of this relation[3], the one suggested by Blagg[4] offers the closest fit to both the planetary orbital radii and the planetary satellite system orbital radii. Blagg's law predicts that the next orbit inside Mercury's orbit would lie at a distance of 0.175 AU from the Sun. This distance is marginally smaller than the radius of the synchronous orbit for a planet orbiting the sun, which lies at a distance $a_{\text{synchronous}} = (GMT_\odot^2/4\pi^2)^{1/3} \simeq 0.177$ AU, assuming $T_\odot = 27$ d. Since the hypothetical planet lies within the synchronous orbit, tidal forces would tend to drag the object towards the Sun, until it breaks up at the Roche radius a_{Roche}. For fluid bodies, $a_{\text{Roche}} \simeq 2.46(\bar{\rho}_\odot/\rho_r)^{1/3} R_\odot$. For material of density $\rho_r \simeq 2$ g cm^{-3} (for example, a refractory material such as graphite) one finds $a_{\text{Roche}} \simeq 2R_\odot$ and for refractory (Ca, Al) silicates of $\rho \simeq 3.5$ g cm^{-3} the Roche limit moves inwards to $\sim 1.6R_\odot$. Such an argument naturally gives rise to a ring system about the Sun analogous to those found about the major planets. Indeed, a similar evolution has been suggested for the origin of the rings of Uranus[5,13]. It is inapplicable, however, in the present case. The time scale τ for a planet of mass m, radius A and initial orbital radius r_0 to spiral into the Sun (mass M and relative energy dissipation rate Q) by tidal drag is

$$\tau \cong \left(\frac{4}{117}\right) Q r_0^{13/2} (M/G)^{1/2} A^{-5} m^{-1} \text{ (seconds)} \qquad (1)$$

Assuming $m = 10^{28}$ g, $A = 10^9$ cm, and $Q > 1$, one finds $\tau > 10^{25}$ s, much greater than the age of the Solar System, $T = 10^{17}$ s. As we argue below, $m \ll 10^{28}$ g (at least at present), so that τ is a lower limit. Of course, this argument would not preclude the possibility that an incident body rather than a body in a slowly decaying orbit could have moved towards the Sun and broken up on a much shorter time scale. A cometary or meteoritic supply or an original refractory condensate in the intra-mercurial region is also possible.

© 1979 Macmillan Journals Ltd

We know of no other evolutionary arguments which would suggest either the present position, mass or other properties of a material ring around the Sun. We therefore consider what present dynamical considerations say about any possible ring system.

A ring of particles in orbit about the Sun will give rise to a gravitational quadrupole moment, adding a source of perturbations to the planetary orbits. The most sensitive probe of such a mass quadrupole source is provided by the orbit of Mercury. Two effects are possible. First, the ring could produce an extra contribution to the advance of the perihelion of Mercury's orbit (as well as the other inner planets). The discrepancy between the observed perihelion advance, and the prediction based on newtonian gravity was originally taken as evidence for a planet or ring inside Mercury's orbit[6]. We shall assume here that general relativity is the correct theory of gravity, and take as an upper limit on any possible contribution to the perihelion advance due to the hypothetical ring the uncertainty in the relativistic contribution, that is, $\Delta\phi_{\rm ring} < 10^{-2}\ \Delta\phi_{\rm GR}$, where $\Delta\phi_{\rm GR}$ is the general relativistic contribution to the perihelion advance, equal to about 43″ per century for Mercury[7]. A straightforward calculation shows that a circular ring of particles of total mass M and orbital radius R (having width and thickness much less than R) gives rise to a perihelion advance

$$\Delta\phi_{\rm ring} = \frac{1}{4}\frac{MR^2c^2}{GM_\odot^2 a(1-e^2)}\Delta\phi_{\rm GR} \qquad (2)$$

where a and e are the semi-major axes and eccentricity of Mercury's orbit, respectively, and $\Delta\phi_{\rm GR}$ is the expected general relativistic contribution to $\Delta\phi$. (Alternatively, the ring is equivalent to a mass quadrupolar moment $J_2 = [MR^2/2]M_\odot R_\odot^2$.) With the observed limit on $\Delta\phi_{\rm ring}$ (or on J_2) we find

$$MR^2 < 4\times10^{48}\ {\rm g\ cm^2} \qquad (3)$$

Precession of the nodes of Mercury's orbit gives a limit which is about two orders of magnitude higher, assuming that the orbital plane of the ring is the same as the invariant plane of the Solar System.

We next consider the size of any hypothetical bodies. Here one is guided by the various dynamical forces acting on the bodies. The Poynting–Robertson effect drags objects in a circular orbit of radius R into the Sun on a time scale[8]

$$t \simeq 3\times10^{-20} AR^2\rho_{\rm r}\ ({\rm years}) \qquad (4)$$

where A(cm) and $\rho_{\rm r}$(g cm^{-3}) are the radius and density of the ring particles. For objects at a few solar radii and densities of a few g cm^{-3}, only kilometre-size objects have survived since the formation of the Solar System. Drag by motion through the solar wind or outer corona are of comparable importance at a few solar radii, negligible at greater distances. We have also examined the so-called Yarkovsky drag on rotating heated bodies[8] (for all angular rotation rates) and find it places a less restrictive lower limit on the allowed size of the particles.

We now consider constraints on the properties of the ring particles by the requirement of survival against solar irradiation. For most materials, the direct effect of sputtering by the solar particle beams will ablate away only a few centimetres of almost any material per 10^9 years. (Sputtering will, however, considerably darken the surface materials and redden the reflected light, making visual observation less likely—see ref. 9.) The fierce solar radiation field will directly heat the bodies, leading to rapid evaporation. Objects at orbital radius R, with radiation absorption coefficient α will be heated to an assumed uniform surface temperature

$$T = \left(\frac{\alpha R_\odot^2}{4R^2}\right)^{1/4} T_\odot \qquad (5)$$

For a very dark material like carbon with $\alpha \simeq 1$, the black-body equilibrium temperature at $4R_\odot$ is $\sim$2,000 K; for more reflective refractory materials (for example alumina, calcium-aluminium silicate) with $\alpha \simeq 0.1$, $T_{\rm eq} \gtrsim 1{,}100$ K. To find the vaporisation rate produced at this temperature, we must know the vapour pressure observed or computed for the assumed material composition of the bodies as a function of temperature. No simple analytical expression exists for the vapour pressure as a function of temperature for most materials. Using present numerical data for the vapour pressure as a function of temperature $p = p(T)$, we estimated the vaporisation rate for a variety of materials[10,11] ($F(T) = p(T)\ (kT/m_{\rm atom})^{-1/2}$ cm^{-2} s^{-1}, where $m_{\rm atom}$ as the atomic mass of the vaporising species). Carbon seems to be both abundant and refractory enough to survive in the near solar environment. Graphite seems the likely form. Lewis and Ney[12] have recently examined the conditions for the condensation of refractory grains in circumstellar envelopes and found that for a broad range of C/O ratios, Fe and Fe_3C condense stably and permit graphite formation over a wide range of vapour pressures below 2,000 K.

Combining the minimum size restrictions set by the Poynting–Robertson effect with the vaporisation by solar irradiation, we find that graphite bodies (absorption coefficient $\alpha \simeq 1$, density $\rho \simeq 2$ g cm^{-3}) of radius $A \gtrsim 10$ km could survive both vaporisation and drag for the age of the Solar System, but only at a distance of about $4R_\odot$. At a distance of only $2R_\odot$, even an object as large as is allowed by considerations of possible tensile strengths ($A \simeq 300$ km) would evaporate, no matter what its composition, in less than 10^9 years.

Finally, we look at the possible destruction of the ring by particle collisions. There are two relevant time scales for the collisional evolution of rotating ring particles. First, there is a relatively short time scale for ring flattening and circularisation of orbits. A straightforward analytical calculation gives for this time scale $t_1 = (t_{\rm orbit}/\pi N)(R/A)^2$, where $t_{\rm orbit}$ is the orbital period at heliocentric distance R and N is the number of ring particles. For $N \simeq 10^6$, $R \simeq 4R_\odot$ and $A \simeq 10$ km, $t_{\rm orbit} \simeq 10^5$ s and $t_1 \simeq 10^2$ yr. After this time, the only particles surviving collisional breakup or particle accumulation are those in circular orbits. The disrupted particles are irrelevant for the present considerations, and we are only concerned with the remaining particles in circular orbits. Detailed numerical calculations[14,15], however, show that the ring subsequently disperses on a much longer time scale $t_2 \simeq (t_{\rm orbit}/3N)(R/A)^4$. For the ring parameters derived above, one has $t_2 = 10^{13}$ yr. Thus, an initially present or later formed ring of 10^6 particles in circular orbits will be stable over the age of the Solar System.

We therefore arrive at a consistent picture of the most massive primordial ring allowed to reside around the Sun. It must lie at a distance $R \gtrsim 4R_\odot$. Its total mass is, therefore $M \lesssim 6\times10^{25}$ g. It could consist in that orbit of at most $N \lesssim 10^6$ objects of minimum radius $A \simeq 10$ km.

Would such objects be visible optically? If they consisted of graphite or other dark refractory materials with an optical albedo of a few per cent, they might be individually detectable with a visual magnitude of $m_v \cong +8$ to $+10$. Such objects would be observable, in practice, only during a total eclipse of the Sun. Their existence does not yet seem to be ruled out by any direct observations[16].

Finally, note that there is one intriguing piece of observational data which may hint at the existence of such a ring, precisely at the minimal allowable radius we derive above. Several IR observations[17,18] at 2.2 μm and at longer wavelengths find an excess emission peak at $4R_\odot$. This peak is not implausibly interpreted as resulting from vaporisation of small silicate grains continually spiralling into the Sun under Poynting-Robertson drag, but we can speculate that the excess may in part be due to a ring of larger bodies in orbit close to the Sun.

Is SS433 a young binary neutron star?

W. Kundt

Institut für Astrophysik der Universität, Auf dem Hügel 71, D-5300 Bonn, FRG

The highly variable X-ray and radio star SS433 has received much attention[1–3] because of its intense emission lines of oscillating frequency[4,5]. These comparatively narrow lines have been identified as two sets of Balmer and He I lines whose redshifts (and blueshifts) vary sinusoidally, according to

$$\lambda_\pm/\lambda_0 = 1.039\{1 \pm [0.0765 \cos \omega t + 0.0544]\} \quad (1)$$

with a probable period[5,6] (161.7±0.3) d, as well as a more intense 'stationary' system. Sharp subcomponents of the 'stationary' system vary in redshift[7] with a period of (13±0.1)d and radial velocity amplitude $K = (76 \pm 7)$ km s^{-1}. This same periodicity probably shows up[8] in the total optical intensity, with an amplitude of some 0.3 mag. I propose here that the moving lines are the result of stimulated emission from the inner edge of an accretion disk around a rapidly spinning neutron star, pumped by cyclotron radiation. The neutron star is in an eccentric orbit of period 13 d around the Of star SS433, and is forced by its accretion disk to precess with a period of 162 d. The 'stationary' emission line system consists of reprocessed starlight from the outer accretion disk, and the X rays together with light from the two oscillating line systems cool the inner edge of the disk which cuts deeply into the co-rotating magnetosphere of the (inclined) neutron star.

The huge red- and blueshifts of the moving emission lines imply that bulk matter is moving with velocities reaching or exceeding one sixth of the speed of light. They have often been interpreted[1] as coming from two antipodal beams; but there are enormous difficulties in producing a pair of almost relativistic, narrow, monoenergetic, and sufficiently dense beams on planetary-system-scales. If, instead, the lines are emitted by matter orbiting around a compact object[2], only their narrowness and sine-shaped law of motion are unexpected. But consider a neutron star as the likely[9] companion of the Of star SS433, whose spin is inclined at an angle χ w.r.t. the normal to the orbit plane and whose magnetic dipole moment is almost at right angles[9] w.r.t. its spin; once matter is transferred from the primary to the neutron star, at a rate exceeding the Eddington rate, it is likely to form an accretion disk[10] in the orbital plane. This disk will cut into the magnetosphere, in the shape of a thin blade[11,12]. Magnetospheric braking will slow down its innermost part to slightly sub-keplerian velocities until magnetic support comes weakly into play. The torque T exerted by the asymmetrically confined dipole field on the neutron star has been calculated by Aly[11]. Averaged over one revolution period

$$T = 2D^2 \sin 2\chi / 3\pi R^3 \quad (2)$$

where D is the magnetic dipole moment and R the radius of the disk's inner edge, and forces the spin to precess around the normal to the disk plane with a period

$$P_{\rm prec} = I\Omega/T = 1\ {\rm yr}\ I_{44.5}\Omega_2 R_7^3 B_{12.5}^{-2}/(2 \sin 2\chi) \quad (3)$$

where I is the moment of inertia, Ω the angular velocity, and B the polar surface field strength. The observed period $P_{\rm prec} = 162$ d requires

$$I_{44.5}\Omega_2 R_7^3 B_{12.5}^{-2}/(2 \sin 2\chi) = 0.44$$

a plausible value, as argued below.

The torque T, when acting on the inner edge of the disk, warps its shape such that orbiting matter acquires a velocity component perpendicular to it which peaks in magnitude where the dipole moment periodically intersects the disk. Radiation emitted at this longitude in near-keplerian motion is seen redshifted, at infinity of a Schwarzschild spacetime, by an amount given by

$$\lambda_\pm/\lambda_0 \approx (1-3u/2)^{-1/2}\{1 \pm (u/2)^{1/2}(1-u)^{-1/2} \times [\sin i \cos \omega t + \cos i\, {\rm d}\theta/{\rm d}\phi]\} \quad (4)$$

Here $u := r_S/r = 2GM/rc^2$ is the inverse radial distance in units of the Schwarzschild radius r_S, i is the inclination angle, ω the orbital angular velocity, ${\rm d}\theta/{\rm d}\phi$ measures the out-of-plane velocity component, and second order effects in u (like the general relativistic light bending effect) have been ignored. A comparison with the observed law of equation (1) yields: $u = 0.05$, $i = 28°$, ${\rm d}\theta/{\rm d}\phi = 0.38$.

In comparing equations (1) and (4), I have assumed that the moving emission lines of SS433 come from the two antipodal spots at the inner edge of an accretion disk where it is most warped, so that the spots move with the precession of the neutron star's spin. For a 1.4 $M_\odot$ neutron star, the value $u = 0.05$ corresponds to the radial distance $R = 20r_S = 0.8 \times 10^7$ cm which has been anticipated in equation (3). Here the (confined) magnetic field strength is of the order of 10^{10} G (if of the order of 3×10^{12} G at the polar caps).

Can such tiny spots emit more than $3L_\odot$ in the form of Balmer lines? For incoherent radiation, the observed intensities would imply, at temperature T, a radiating area in excess of $(10^{12}T_4^{-1/2}\ {\rm cm})^2$. Velocity broadening of the lines is <10% of their velocity shift, hence in the present model the size of the radiating spots must be $<(R/10)^2$ each, and lasing must result in an enhancement by factors of the order of $10^8 T_8^{-1}$. Note, however, that coherent radiation from an antipodal pair of spots at the inner edge of an accretion disk offers plausible explanations for the following observations:

(1) the two moving line systems often show mirror-image symmetry;

(2) sharp lines are more easily produced by a coherent mechanism than by an incoherent one, as well as rapid time variability;

(3) observed deviations from the strict redshift law in equation (1), on the time scale of days, can be understood as being produced by matter sinking more deeply towards the neutron star's surface (and eventually being accreted).

Before discussing the hypothesised laser in more detail, the overall features of this model should be considered. A binary orbital period of 13 d corresponds to a semi-major axis

$$a = (GM/\omega^2)^{1/3} = 5 \times 10^{12}\ {\rm cm}\ (M/30M_\odot)^{1/3} \quad (5)$$

$M := M_1 + M_2$, and to orbital velocities

$$v_1 \leqslant 13\ {\rm km\ s^{-1}} (M/30M_\odot)^{-2/3} \left(\frac{1+\varepsilon}{1-\varepsilon}\right)^{1/2} \quad (6)$$

$$v_2 \sin i = (M_1/M_2) v_1 \sin i \leqslant 1.3 \times 10^2 \quad {\rm km\ s^{-1}}$$

where ε = numerical eccentricity, and $\sin i = 0.48$ has been

0028–0836/79/440052—02$01.00

taken from above. The close separation of $a = 0.3$ AU is consistent with Roche lobe overflow from the primary (whose mass is assumed to be $\sim 28.6 M_\odot$), and with a strong illumination of the accretion disk. The small velocity amplitude of the primary is consistent with the observational constraint[3] $v_1 < 50$ km s^{-1}. An observed $K = 76 \pm 7$ km s^{-1} for the motion of a secondary object is consistent with our $v_2 \sin i \leq 130$ km s^{-1} because the strongest subcomponents will be emitted from the near side of the accretion disk which rotates in a retrograde sense. A variation in the total optical luminosity is explained by a variable binary separation, that is, by a variable illumination of the disk. The disk is probably transparent in the optical continuum but opaque in the UV, IR and optical lines, and retarded cooling would explain an asymmetrical light curve. Note that according to Press *et al.*[13], a substantial orbital eccentricity is expected to survive for some 10^{10} yr at the calculated separation. In this picture, the disk should also be identified with the large and variable IR source discussed by Giles *et al.*[14]. Finally, the relative phases, during the 13-d cycle, of the maxima in redshift[7] and intensity[8] can be explained by a substantial angle between the line of apsides and the line of nodes.

What is the structure of the (inner edge of the) disk? If confined by a 10^{10} G magnetic field, its internal pressure must be $> p = 10^{18.6}$ dyn cm^{-2}, corresponding to a particle density $n = p/kT \geq 10^{28.6} T_6^{-1}$ cm^{-3}. This pressure is higher than typical values for accretion disks (see refs 15, 16), probably because a high spin rate of the neutron star hampers accretion so that matter piles up and settles deeper into the magnetosphere. The inner edge of the disk is heated by interaction with the rapidly time-varying magnetic field, in addition to internal dissipation, and cooled by incoherent X-ray emission[17] and coherent line radiation. A total radiation power $L \geq 3 \times 10^{35}$ erg s^{-1} emitted near $r = 10^7$ cm implies an effective temperature $T_{\rm eff} \approx 10^6$ K, but X-ray energies ≥ 10 keV indicate the presence of a much hotter corona, with electron temperatures in excess of 10^8 K. In these conditions (with LTE assumed), the Saha equation yields a (maximum) neutral abundance fraction

$$\gamma = 4 \times 10^{-8} h_{20} T_8^{-3/2} \tag{7}$$

so that the corona is highly ionised. The scale height h is given by

$$h = (kTr^3/GM_* M_{\rm p})^{1/2} = 3 \times 10^5 \text{ cm } T_8^{1/2} r_7^{3/2} \tag{8}$$

where M_* is the mass of the neutron star, and $M_{\rm p}$ the proton mass.

Assuming that the dissipative interaction between disk and rotating magnet leads predominantly to cyclotron radiation, whose power

$$L = N\sigma_{\rm T} c B^2/4\pi = 2 \times 10^5 N B_{12}^2 \quad \text{erg s}^{-1} \tag{9}$$

should equal the total emission, the presence of $N \geq 10^{30}$ electrons is implied ($\sigma_{\rm T}$ = Thomson cross section). This radiation is emitted at frequencies $\nu_0 = eB/2\pi m_0 c = 3 \times 10^{16}$ Hz B_{12} and its higher harmonics $\nu_n = (n+1)\nu_0$ caused by a marginally relativistic beaming. The corresponding brightness temperatures

$$\begin{aligned} T_{\rm b} &\approx 2\pi^2 m_0 c^2 e (\int n \, {\rm d}s)(\nu/\Delta\nu)\beta_\perp^{2n}/3B(n+1)^3 k \\ &= 2 \times 10^6 {\rm K} (\int n \, {\rm d}s)_{14} (\nu/\Delta\nu)_1 \beta_\perp^{2n} B_{12}^{-1} (n+1)^{-3} \end{aligned} \tag{10}$$

exceed 10^6 K up to some $n (\geq 0)$ for almost relativistic electron velocities $\mathbf{v} = c\boldsymbol{\beta}$ and a magnetised column density $\int n \, {\rm d}s \gg 10^{13}$ cm^{-2}. This UV radiation floods the inner disk. It ionises the diskal gas, and is partially inverse-Compton scattered to X-ray energies in the hot corona. It is preferentially generated where the disk is most warped, leading to the highest brightness temperatures, to the highest ionisation rates, and to stimulated emission of all the lines of the neutral component. As absorption cross-sections in the lines exceed 10^{-17} cm^2, the lasing photosphere is extremely thin. Note that the absence of observable pressure broadening implies $T \geq 10^6 K n_{21}^{2/3}$, and that the absence of magnetic signature in the lines (shifts or circular polarisation[4]) implies magnetic field strengths either below 10^6 G or above 10^{10} G. The latter is probably realised. (The former alternative could hold were a non-magnetised photon cushion separating the magnetosphere from the—probably similarly magnetised—central disk.)

Why does SS433 look so different from other binary X-ray sources which involve a neutron star? It may be due to the neutron star's high spin rate, preventing rapid accretion. In the absence of a complete solution[16], one may argue that a low or vanishing accretion rate from a near disk requires a high enough angular velocity of the star, such that the (neutral) force balance radius $r_{\rm fb} = (GM_*/\Omega^2)^{1/3}$ does not greatly exceed the extent $r_{\rm cf}$ of the closed field line region. For an inclined (static) dipole field and a perfectly conducting infinitely thin 'disk', of inner radius R, the ratio $\xi := r_{\rm cf}/R$ obeys[11,12]

$$\xi = [1 + (2tg\chi/\pi \cos\phi)^2]^{1/2}, \tag{11}$$

where χ is the elevation angle of the dipole and ϕ its azimuthal angle. In my model, χ ranges twice from 0° to some maximum angle during one cycle, whence $\xi \geq 1$, and the condition $r_{\rm fb} \leq r_{\rm cf}$ implies

$$\Omega \geq [GM_*/(\xi R)^3]^{1/2} \approx 6 \times 10^2 \xi^{-3/2} s^{-1} \tag{12}$$

This estimate is unrealistically high, and suggests that the above criterion is too strict in a non-static situation. In any case, the neutron star's spin rate may be very high, comparable with that of the Vela pulsar, and its age correspondingly low, $\leq 10^4$ yr; see ref. 10.

For such a low age, one should still see the supernova remnant that was blown off at the neutron star's birth. An association with the remnant W 50 has been suggested[19].

Finally we should consider the radio structure of SS433. If the secondary involves a rapidly rotating neutron star, there should be an open field line region connecting its polar caps to its wind zone and along which a pulsar wind is blown out. This relativistic wind must intersect the primary's ordinary stellar wind, and give rise to an extended radio structure that shares both the 13-d and the 162-d period. As the pulsar wind will be orientated w.r.t. the neutron star's spin axis, it will illuminate the primary at a variable rate during its 13-d orbital and 162-d precession cycle, thus giving rise to a variable brightness of SS433, as observed[6].

I thank E. van den Heuvel, Gopal-Krishna, A. King, M. Robnik, C. Salter, E. Schrüfer, K. Weiler and W. M. Fawley for stimulating discussions and G. Wright for reading the manuscript.

Dielectric breakdown by electrically induced chemical decomposition

T. B. Tang & M. M. Chaudhri

Physics and Chemistry of Solids, Cavendish Laboratory, Madingley Road, Cambridge, UK

Experimental observations and our interpretation of electrical current instabilities in single crystals of ionic metal azides are described here. The subsequent insulation breakdown occurs over wide ranges of fields and delay times. The fields, at room temperature, are of the order MV m^{-1} or lower, and are 2–3 orders of magnitude smaller than the usual dielectric strength found in a homogeneous bulk solid. The breakdown is strongly time dependent and the delay after the application of the field can be up to a few days. We suggest for this low-field long-delay breakdown an 'electrochemical' mechanism which seems not to have been envisaged before.

Thoma[1] attributed breakdowns which exhibit extremely long delay times to the growth of conduction filaments due to dislocation structure. Narayan *et al.*[2] observed that breakdown in MgO single crystals at 1,300 K occurred in a field of 0.1 MV m^{-1} after >100 h. They proposed that during this incubation period the properties of the materials in the vicinity of the dislocations and small-angle grain boundaries changed. The changes increased the conductance along these pathways, leading to high conductivity filaments, local heating and dielectric breakdown. However, they did not specify the nature of the structural and electrical changes, nor the underlying mechanisms. We have set up a more detailed model for the breakdown in metal azides, but here we will, after summarising the empirical observations, describe only briefly our proposed scheme.

Figure 1 illustrates the behaviour of the current conducted by silver azide; the cases of thallous, lead and sodium azides have been found to be similar. At low fields, the conduction is by mobile interstitial Ag^+ according to previous work on polycrystalline samples[3,4]. We ascribe the decay of current with time to ionic polarisation at the electrodes, and this is supported by the frequency dependence of a.c. conductivity[5].

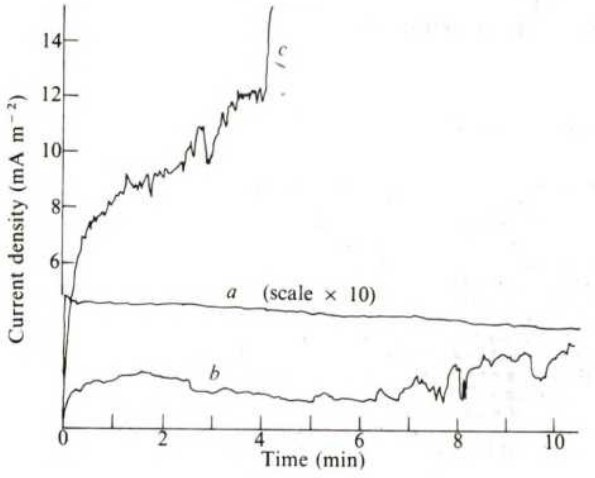

Fig. 1 Current conducted along the *c*-axis of a AgN_3 crystal at a field of *a*, 3.3; *b*, 13 and *c*, 67 kV m^{-1}, in ultrahigh vacuum, and with tantalum pressure-contacted electrodes; qualitatively the same behaviour is observed with silver and graphite electrodes.

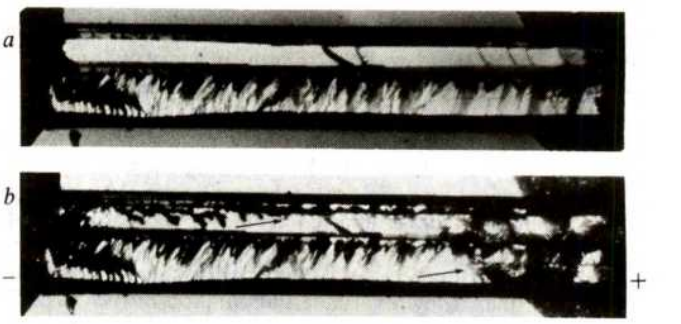

Fig. 2 Photomicrographs of a AgN_3 crystal: *a*, before; and *b*, 5 min after being subjected to 130 kV m^{-1}, arrows indicate new features formed ×95.

At moderate fields >15 kV m^{-1} (400, 800 and 200 kV m^{-1} in the cases of TlN_3, $Pb(N_3)_2$ and NaN_3 respectively), the current displays large-amplitude non-periodic fluctuations; its average value also increases with time, and at a faster rate when the field is stronger. An estimation of the interfacial fields at the polarised contacts[5] suggests that the fluctuations are caused by the double injection of electrons and holes into the crystal. We believe that the continuous increase in the current is caused by the formation of metallic filament-like films on the crystal surface; such electrical behaviour has been shown to exist for the case of ultra-thin discontinuous metal films growing on insulating substrates[6,7].

In these fields, silver and lead azides have been shown[8] to give off nitrogen at rates much greater than those corresponding to the electrolysis of the crystals as estimated from their ionic conductivities. Based on a comparison with the mechanism of thermal decomposition of silver azide[9], we propose the following scheme of elementary steps for the production of surface films. Electrons injected into the conduction band of the insulator constitute a non-equilibrium concentration and so, in their drift towards the anode, a finite number of them may be localised at the electron traps. An interstitial cation may then get discharged at a filled trap, which is thereby reset. On the surface, neutral atoms migrate (see, for example, the case of silver cyanamide[10]) to form aggregates so that the discharge is irreversible. The agglomeration gives rise to, first, a network of thin films and, at later stages, clusters of discrete particles on the surface. The appearance of such metal pebbles has been confirmed (Figs 2 and 3); energy dispersive X-ray analyses have shown them to be silver. (See also ref. 9 for transmission electron micrographs of 'pebbles' formed by thermal decomposition.)

Fig. 3 Electron micrograph of crystal in Fig. 2*b*: surface features are resolved into 'pebbles' ×1,350.

We found that if, during the initial stage of current increase the field was removed, the conductivity returned to its original value. The removal of the field will very quickly stop further generation of silver on the crystal surface, but the accretion of metal atoms in the films at the ambient temperature will continue to change their network structure; the 'pebbles' are permanent, but their number at this stage is small. This means that the number density of the films will continue to decrease with time, and after a sufficiently long time the conductivity will return to the original bulk value. In the accompanying process of field injection of holes, valence electrons are extracted into the anode. The holes drift towards the cathode, some of them combining bimolecularly on the way: $N_3 + N_3 \rightarrow 3N_2$. This process maintains stoichiometry, and leads to the formation and evolution of nitrogen away from the anode[11].

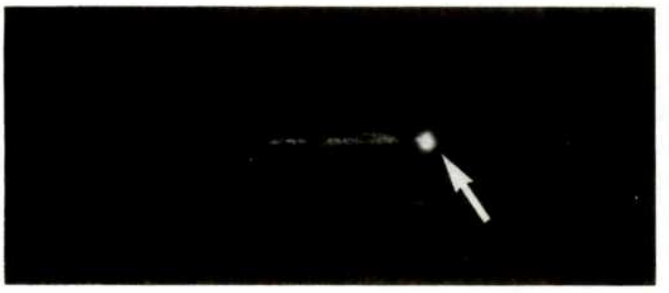

Fig. 4 A AgN_3 crystal (1.35 mm long) supporting a corona discharge (arrowed) without dielectric breakdown.

The dielectric breakdown is identified as the current runaway arising from the growth of the metal-like films in number and in size. It is therefore expected to occur after an interval of time that is longer for a lower field, when the production rate of metal atoms is slower, provided the field exceeds the limiting value for the onset of bipolar injection. Indeed we have shown that, for silver azide, the time to breakdown[5] is <1 s in a d.c. field of 400 kV m^{-1} or greater, increasing to 5 days at 15 kV m^{-1}; the other three azides show a similar wide range of breakdown times. Also, when the voltage was applied through only one conducting contact no breakdown was observed after many minutes at an estimated field of 300 kV m^{-1} (crystal in air: Fig. 4) or 1 MV m^{-1} (crystal in oil), indicating that the injection of non-equilibrium carriers is necessary. A similar result was obtained in the case of lead azide insulated with Mylar at both contacts[12]. Our proposed mechanism predicts that post-breakdown disruptions (due to localised heating by the electronic current in the film network) may start away from either electrode, a fact we have experimentally demonstrated[5] but which cannot easily be explained in alternative models previously put forward by other authors[13].

Finally, we suggest that breakdowns of extended delay times may be brought about by metallic conduction caused by certain 'electrical decomposition' processes in some ionic metal compounds besides the azides, such as halides, iodides, oxides and hydrides.

We thank Dr J. E. Field and Dr J. T. Hagan for helpful comments, the SRC for an equipment grant, and Procurement Executive, Ministry of Defence for a studentship to T.B.T.

Abnormal characteristics in crystallisation of $Ca(PO_3)_2$ glass

Yoshihiro Abe

Department of Inorganic Materials, Nagoya Institute of Technology, Gokiso-cho, Showa-ku, Nagoya 466, Japan

Although glass is known not to crystallise below the glass transition temperature (T_g), some block specimens of metaphosphate glasses such as $Ca(PO_3)_2$, $Sr(PO_3)_2$ and $Ba(PO_3)_2$ have been found to crystallise easily at temperatures considerably lower than T_g; however, thin films of the glasses do not exhibit this behaviour[1–3]. The intrinsic characteristics of $Ca(PO_3)_2$ considered here suggest that under stress the rate of crystal growth depends on thickness, and that long polycrystalline fibres may be produced in which the crystals are orientated towards the direction of elongation.

When the chemical composition of a glass is the same as that of the growing crystal, equation (1) is applicable for most glasses[4],

$$u\eta/\Delta T \approx 0.1 \quad (1)$$

where u is crystal growth rate (cm s^{-1}), η is viscosity (P), and ΔT is the degree of undercooling. In $Ca(PO_3)_2$ glass, the crystalline phase has the same chemical composition as that of the glass. Hence, u is calculated from equation (1) to be $\approx 10^{-7}$ μm min^{-1} or several micrometres per 100 yr at T_g (melting point of β-$Ca(PO_3)_2$ = 980 °C, $T_g \approx 500$ °C, $\eta \approx 10^{14}$ P). This calculated rate of crystal growth is almost the same as that obtained by extapolating the experimental data[1] for the thin film at temperatures higher than T_g. Thus, the crystal growth rate (u) of the thin film holds for equation (1), showing the usual crystallisation mechanism. However, u of the block specimen of $Ca(PO_3)_2$ glass is extraordinarily large reaching 10^7–10^8 times that of the thin film at temperatures near T_g, thus showing an unusual crystallisation mechanism. This abnormally high rate of

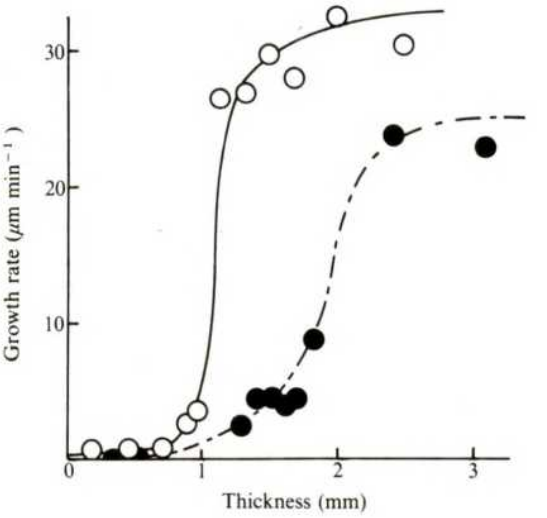

Fig. 1 Dependence of the crystal growth rate on the thickness of the $Ca(PO_3)_2$ glass plate specimen. ○, 560 °C; ●, 540 °C.

0028–0836/79/440055—02$01.00

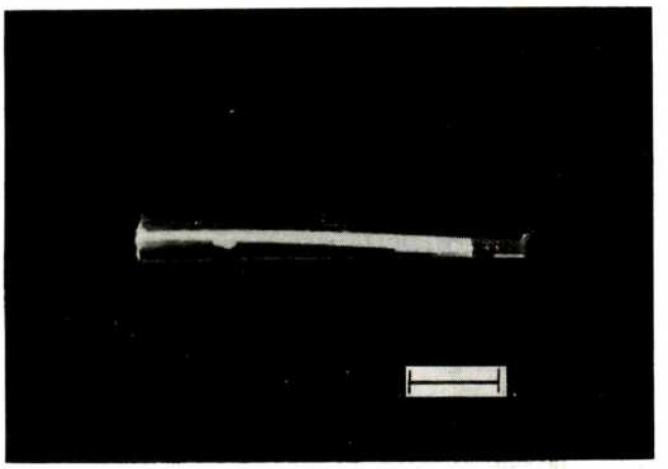

Fig. 2 Photo of orientated crystallisation in an elongated $Ca(PO_3)_2$ glass rod. Elongation, 300% at 540 °C; Heat treatment for the crystallisation, 510 °C for 6 h. Scale bar, 5 mm.

crystal growth for block specimen of $Ca(PO_3)_2$ glass has been explained in terms of induced tension in the molecular chains at the glass–crystal interface, where tension is induced by a volume difference between the crystalline and glassy phases[1].

These results suggest that the crystal growth rate depends on the shape or thickness of the glass specimen. Figure 1 shows the dependence of the rate of hemispherulitic crystal growth on the thickness of $Ca(PO_3)_2$ glass plate specimen. Abrupt change in the growth rate occurs at ≈1 mm thickness at 560 °C and ≈2 mm thickness at 540 °C, respectively, the critical thickness at which these abrupt changes take place becoming larger as the temperature decreases. I believe that this critical thickness is determined by competition between the rate of relaxation of the induced tension in the molecular chains at a growing crystal–glass interface and the rate of the crystal growth (assumed to be without stress relaxation) at a given temperature.

Another characteristic crystallisation property for $Ca(PO_3)_2$ glass is crystallisation orientated towards the direction of tension. A fine glass rod (3–4 mm in diameter) was produced from a $Ca(PO_3)_2$ glass rod held at 540°C (a little higher than T_g) by pulling and quenching under a force of 8 kg cm^{-2} to become three times the length of the original rod. This specimen was heated at 510 °C for 6 h under no load, resulting in orientated crystallisation towards the direction of elongation of the specimen; note that although the crystallisation occurred preferentially inside the glass rod, the surface of the specimen remained uncrystallised (Fig. 2). When not elongated, hemispherulite only usually grows at arbitrary places of the glass surface[1,2]; therefore orientated crystallisation must be due to stretching of the glass specimen which results in orientation of molecular chains in the glass towards the elongation direction. At temperatures around T_g, although the viscosity is low enough to allow the glass to be stretched by a sufficiently large tensile stress, the mobility of the molecular chains or chain segments is not high enough for the orientation produced by stretching to be lost during the thermal treatment to which the glass is subjected. The crystal growth rate towards the elongation direction is very high, reaching at least 10 times the growth rate of hemispherulite—usually grown from the block specimen of the glass prepared with no applied stress, the growth rate depending on conditions for the preparation of the fine rod (elongation times, elongation temperatures, rate of quenching).

It is surprising that $Ca(PO_3)_2$ glass exhibits intrinsic crystallisation below T_g, that the crystal growth rate depends on the thickness, and that the crystallisation may be orientated under tension. These phenomena have not yet been found in inorganic glasses. I believe that these crystallisation characteristics are due to structural features in that $Ca(PO_3)_2$ is comprised of molecular chains in both the glass and crystal. We can expect unusual behaviour in this type of glass that has never been observed in a glass network structure such as commercial industrial glasses.

$^{13}C/^{12}C$ and $^{34}S/^{32}S$ ratios in magmatic gases from ridge volcanism in Afar

P. Allard

Centre des Faibles Radioactivités, Research Group on Volcanology, CNRS 91 190 Gif/Yvette, France

Most data on the stable isotope composition of deep-seated carbon and sulphur come from igneous rocks and low-temperature gases. Very little information comes from high-temperature gases which escape from magmas ($T = 1{,}000 \pm 200$ °C), even though these are the best specimens of primary igneous fluids. Moreover, the only available $^{13}C/^{12}C$ data on carbon in high-temperature basaltic gases[2–4] are largely divergent: low ratios from −14 to −26‰ versus PDB were measured in gases from Hawaii[2,3,5], which is consistent with the values for reduced carbon in basalts[6], whereas higher ratios around −6.5‰, typical of carbon in most of carbonatites[7,8], diamonds[9] and kimberlites[10], have been found in gases from northern Afar[4] (P.A. and M. Javoy, in preparation). The high-temperature gas samples collected from the November 1978 Asal rift eruption, southern Afar[1], have provided new isotope data on basaltic igneous volatiles, released from upper mantle magmatism[11].

Four gas samples were collected from the fissure which generated the eruption ($T = 1{,}070$ °C) and another four samples were taken from outpoured lava flows, 60 m away from the fissure ($T = 800$ °C)[1].

Chemical compositions were determined by gas chromatography and are reported in Table 1 together with the isotopic results. For isotopic measurements, CO_2 and SO_2 were separated from the mixtures by differential freezing in a high vacuum Pyrex line: after the non-condensible gases in liquid nitrogen were pumped (CO, H_2, COS, N_2, O_2 and Ar), melting dimethylbutane (−140 °C) and dry ice acetone (−80 °C) traps were used to isolate CO_2 from SO_2, and SO_2 from residual water vapour, respectively. Complete extraction was controlled with a precision pressure gauge, and the proportions of gas recovered agreed with the chromatographic results (±2%). Isotopic analyses were performed on a double-collecting micromass spectrometer. Results are expressed in the usual δ notation (1) (ref. 12). Standards are PDB for carbon, SMOW for oxygen and Canyon Diablo Troïlite for sulphur. The accuracy of the mass spectrometric analyses (1σ) is better than 0.1‰ for carbon and oxygen, 0.3‰ for sulphur.

$$\delta = \frac{R_{\text{sample}}}{R_{\text{standard}}} - 1 \times 1{,}000, \qquad (1)$$

where $R = {}^{13}C/{}^{12}C$ or $^{34}S/^{32}S$.

Although the samples are largely air contaminated, as shown by their high N_2 contents and $O_2 + Ar/N_2$ ratios which are similar to the atmospheric ratio (0.280), the corresponding CO_2 air contribution amounts to <1% of the total CO_2 content of the samples, and is only significant in the 800 °C samples, particularly in sample no. 13. Assuming that ~0.03 mol% of atmospheric CO_2 with a $\delta^{13}C \simeq -7$‰ were added to those samples which contain about 78 mol% of N_2, we can restore the $\delta^{13}C$ of true volcanic CO_2: corrected values are in parentheses in Table

ND, not determined; 0 means under the limits of detection. All the samples were collected in previously evacuated Pyrex bottles containing P_2O_5 desiccator in excess to trap water vapour. A silica collection pipe was used to lead the gases into the bottles[1].

1. Except for sample 13, corrections are within the accuracy possible for mass spectrometric analyses and allow a reliable determination of the $^{13}C/^{12}C$ ratio in volcanic CO_2.

CO_2 accounts for nearly the whole carbon content of the gases, as CO and COS when detected are only minor components. Note that both reverse C/S atomic ratios and opposite-sign $\delta^{13}C$ values distinguish the 800 °C samples (C/S > 10, $\delta^{13}C>0$) from 1,070 °C samples (C/S = 0.2, $\delta^{13}C<0$). Such a discrepancy, and such a high $\delta^{13}C$(+2.2‰ versus PDB) in the gases from lava flows, were surprising: the exhibited value fits in with the isotopic range for ^{13}C-rich marine limestones[6].

This might be related to the presence, near to the eruption point, of lacustrine carbonates deposited from the Asal lake basin (155 m below sea level) since this one was isolated from the marine gulf of Ghoubbet–Tadjurah and extended over a wider area of the Asal graben's floor than it is at present[13]. Carbonates were collected in the field near to the sampling sites for chemical and isotopic composition analysis (Table 2).

The results ($\delta^{13}C=+0.85‰$) show that a thermal decomposition of such a magnesium-rich calcite could produce CO_2 with a $\delta^{13}C$ similar to that found in the 800 °C samples: if we assume that isotope equilibrium was maintained between the carbonate and the CO_2 released, and that the fractionation factor for calcite can be used, then a 1.4‰ ^{13}C enrichment in CO_2 would correspond to an equilibrium temperature of about 800 °C (ref. 14). Isotopic equilibrium conditions may have been maintained by the thickness of the lava field (10m) that allowed the gases to escape only from a few points where the upper lava crust was broken. Thus, carbonate sediments, partly overlapped by the lava flows, seem the most probable source for the CO_2 sampled outside the fissure.

$\delta^{13}C$ of sample A88 (+0.2‰), collected from one of the two vents we used above the erupting fissure, suggests a local mixing between a light magmatic CO_2 and the carbonate-derived CO_2. If we consider the $\delta^{13}C$ value from sample A92 ($\simeq-6‰$) the most representative of unmixed carbon dioxide, we may evaluate the possible contributions from carbonate-derived CO_2 to the other three samples: 9%, 76% and 15% for samples A89, A88 and G89, respectively. It is possible that superficial CO_2 may also have made a (small) contribution to sample A92.

This −6‰ value for uncontaminated CO_2 from the fissure is very similar to that of magmatic CO_2 from the Erta Ale lava lake, on the northernmost spreading axis in Afar ($-6.4\pm0.4‰$)[4]. It could also be compared with the $\delta^{13}C$ of CO_2 trapped in fresh tholeïtic basalts from the mid-Atlantic ($-7.6\pm0.5‰$)[15] and east Pacific (−5.4 to −5.8‰)[16] sub-oceanic ridges. Then, it falls within the isotopic range for most of carbonatites, diamonds and kimberlites in which carbon is usually considered to derive from a deep-seated source.

The shallowness of the mantle beneath the Asal–Ghoubbet ridge[11], the thinning of the oceanic crust beneath the axis indicated by the seismic profiles[17], the lack of continental-type crust, the axial situation of the eruption point[1], the high temperature of the gases and their close relationship to the magma feeding channel, suggested that the mantle would be a probable source of the CO_2 released from the fissure. The consistency of the $\delta^{13}C$ obtained with that of most of presumed deep-seated carbon-rich reservoirs supports such an origin. The close similarity of the $^{13}C/^{12}C$ ratios in Asal and Erta Ale magmatic gases indicates that the mantle beneath Afar's spreading axis would have a uniform carbon isotope composition, comparable with that of carbon from other sub-oceanic ridges[15–16].

The much lower values measured in magmatic gases from Hawaii[2,3,5] suggest either (1) lighter $^{13}C/^{12}C$ ratios in Hawaiian magma sources, the carbon in plumes from deep mantle being relatively ^{13}C-depleted compared with carbon in shallow mantle rises beneath oceanic ridges; or (2) only local contributions as some of the gases were collected from lavas having flooded over organic material[2]. The difference between Asal samples from the fissure and outside the fissure emphasises that lava flows are inadequate sampling sites, being easily contaminated by environmental fluids.

SO_2 constitutes the whole sulphur content of the gases, as H_2S and COS are trace components. Thermodynamical equilibrium in collection conditions (1 atm, 1,070 °C and $p_{O_2}=10^{-9.4}$ atm)[1] would lead to higher H_2S/SO_2 ratios than are found in the samples (8×10^{-3} compared with 10^{-4}). The lower O_2+Ar/N_2 ratios in samples than in air indicate that high-temperature air oxidation would be responsible in the reduction of the H_2S proportions. Residual traces of H_2S could also have later reacted with SO_2 in the sampling bottles, according to the reaction

$$2H_2S+SO_2\rightleftarrows3S+2H_2O$$

which brings about a relative ^{34}S enrichment in SO_2. But the lack of sulphur precipitation in the bottles during the few days that they were waiting for analysis suggests that small proportions of H_2S compared with SO_2 made this reaction inefficient. (Water vapour, which favours the reaction, was trapped on P_2O_5 desiccator.) Hence, the $\delta^{34}S$ of SO_2 would account for the original $\delta^{34}S$ of total sulphur in the gases. $\delta^{34}S$ in 1,070 °C samples are homogeneous, around a mean value of −2.8‰ versus CD standard; those in 800 °C samples are less homogeneous, but they enclose the former value.

Table 2 Chemical and isotopic compositions of lacustrine carbonates from Asal rift

	(wt%)	$\delta^{13}C$ vs PDB (‰ ± 0.1)	$\delta^{18}O$ vs SMOW (‰ ± 0.1)
$CaCO_3$	55%		
$MgCO_3$	28%	+0.82	+44.2
Amorphous silica	17%	+0.88	+44.6

Chemical analyses were carried out using an X-ray energy dispersion spectrometer. For isotopic analyses, 1 mg of carbonate was reacted with 100% H_3PO_4 acid at 50 °C for 12 h, after heating 390 °C for 45 min.

This −2.8‰ $\delta^{34}S$ is low in the classical range for igneous sulphur in basaltic rocks[18–20] and fumarole gases[21], the average composition of which usually lies close to the meteoritic standard value. Comparison with the $\delta^{34}S$ of SO_2 from Erta Ale, +1.0 ± 0.3‰ (P.A. and M. Javoy, unpublished data), suggests that sulphur in Asal gases originated from a slightly ^{34}S-depleted source, unless continuous loss of SO_2 involved a progressive ^{34}S depletion in the residual sulphur which escaped from the magma, as the feeding intrusion seems to have been a rather closed system[1] and our samples were collected during the later degassing trend of the eruption. If we assume that the initial $\delta^{34}S$ of total sulphur in the magma was near zero, that about 90% of the original sulphur content had already escaped at the collection time and that a Rayleigh-type isotope distillation took place between SO_2 and the magmatic sulphides, then a fractionation factor of 1.00122 is obtained; this is compatible with the value extrapolated from Sakai's data for the SO_2/S^{2-} equilibrium fractionation at temperatures of about 1,200 °C (ref. 22). Otherwise, kinetic isotope fractionation would have concentrated ^{34}S in the residual sulphur and led to a higher ratio than is observed.

This relatively low $\delta^{34}S$ excludes superficial contributions to the volcanic fluids from sulphates in the marine waters which circulate into the graben from the Ghoubbet to Asal lake (3,900 mg l^{-1})[23] and in the saline waters of the lake itself (4,300 mg l^{-1}) which is 2 km away from the eruption point: the SO_2 produced by high-temperature reduction of such sulphates ($\delta^{34}S \simeq +20$‰)[23] would actually be ^{34}S-rich compared with SO_2 in the gases, isotope fractionation between SO_4^{2-} and SO_2 remaining close to zero at temperatures above 600 °C (ref. 22). A similar lack of chloride contributed by the environment was previously reported from chemical analyses of gases and related sublimates[1].

Thus, carbon and sulphur outgassed from the fracture which generated the recent Asal eruption derived from a probable mantle source because of both the exceptional tectonic setting of the Asal rift and their stable isotope composition which was similar to that of comparable deep-seated material.

This work was supported by the Programme Interdisciplinaire de Recherche sur la Prévision et la Surveillance des Eruptions Volcaniques of the CNRS. I thank Drs R. Letolle, and C. Pierre for assistance; Drs J. C. Duplessy and C. C. Jehanno for analyses of carbonates and Dr Y. Bottinga for his criticism.

The Lizard complex as an ophiolite

G. A. Kirby

Deep Geology Unit, Institute of Geological Sciences, Keyworth, Nottingham, UK

The Lizard complex of south Cornwall consists of an assemblage of peridotites, gabbros, hornblende schists, metasediments, dolerites and metadolerites and acid-basic banded gneisses (the Kennack gneisses). It is bordered to the north by a zone of chaotic sediments with phacoidal inclusions of pillow lavas, greywackes and quartzites (the so-called Meneage crush zone). This zone can be traced eastwards into the Roseland district of south Cornwall[1]. The age of the complex is uncertain. Dates (largely K–Ar) obtained from the Kennack Gneiss and the majority of hornblende schists are mainly between 370 and 390 Myr, although Green[2,3] considered the peridotite to be older than the oldest date obtained from the hornblende schists, at 492 Myr. Metadolerite dykes have recently[4] been given ages of approximately 400 Myr. All the above are thought to represent minimum ages due to the possibility of argon loss during subsequent uplift, cooling and mild metamorphism. Since the work of Green[3], the Lizard complex has been regarded by many as the type example of a hot diapiric mantle intrusion into continental crust. Intrusion is thought to have occurred during a period of regional metamorphism and to have resulted in the imposition of a contact dynamothermal aureole on the hornblende schists at the margin of the peridotite body. The gabbro is regarded as a later and unrelated intrusion, and the Kennack gneisses were attributed to intrusion of acid magma along sheared basic dykes in peridotite. Thayer[5] suggested that the complex was ophiolitic, basing his views on the field relationships of gabbros and peridotites which indicated that the two lithologies might be temporally and genetically related. General comparisons have since been made between the Lizard complex and the well-documented ophiolote sequences[6–10], although little detail has generally been given. I provide here relevant details which suggest that the Lizard complex is ophiolitic in origin.

The east coast section of the Lizard complex is thought to form a rock association distinct from the remainder of the complex and to be separated by a major fault (Fig. 1*a*). There are four east–west trending divisions of the east coast section, which from north to south are: a dyke complex in gabbro; massive, variable and layered gabbro; troctolites and related rocks in peridotite; and peridotite.

The dyke complex consists of subequal amounts of variable gabbros and NW–SE trending subvertical tholeiitic metadolerite dykes. Small amounts of hornblende leucodiorite form segregations in the gabbro and have locally intruded fractured metadolerite dykes forming net-veined complexes. The base of the dyke complex is at Godrevy Cove where there is a rapid transition southwards into gabbro containing only a small percentage of dykes. Subvertical, E–W trending cumulate layering produced by varying proportions of olivine, plagioclase and occasionally clinopyroxene is locally preserved; rare mineralogically graded units 'young' to the north. The present orientation of the cumulates demonstrates that the whole sequence has been rotated through a large angle downwards to the north about an east–west axis. These cumulates are thought to have been deposited on a subhorizontal or gently dipping surface on a floor of peridotite, although subsequent gabbro intrusion and high temperature deformation have obscured many of the original relationships. The remaining gabbro has less well-defined mineralogical variations and is variable between strongly laminated (mostly the plagioclase-rich varieties) and non-laminated. The contact with peridotite at

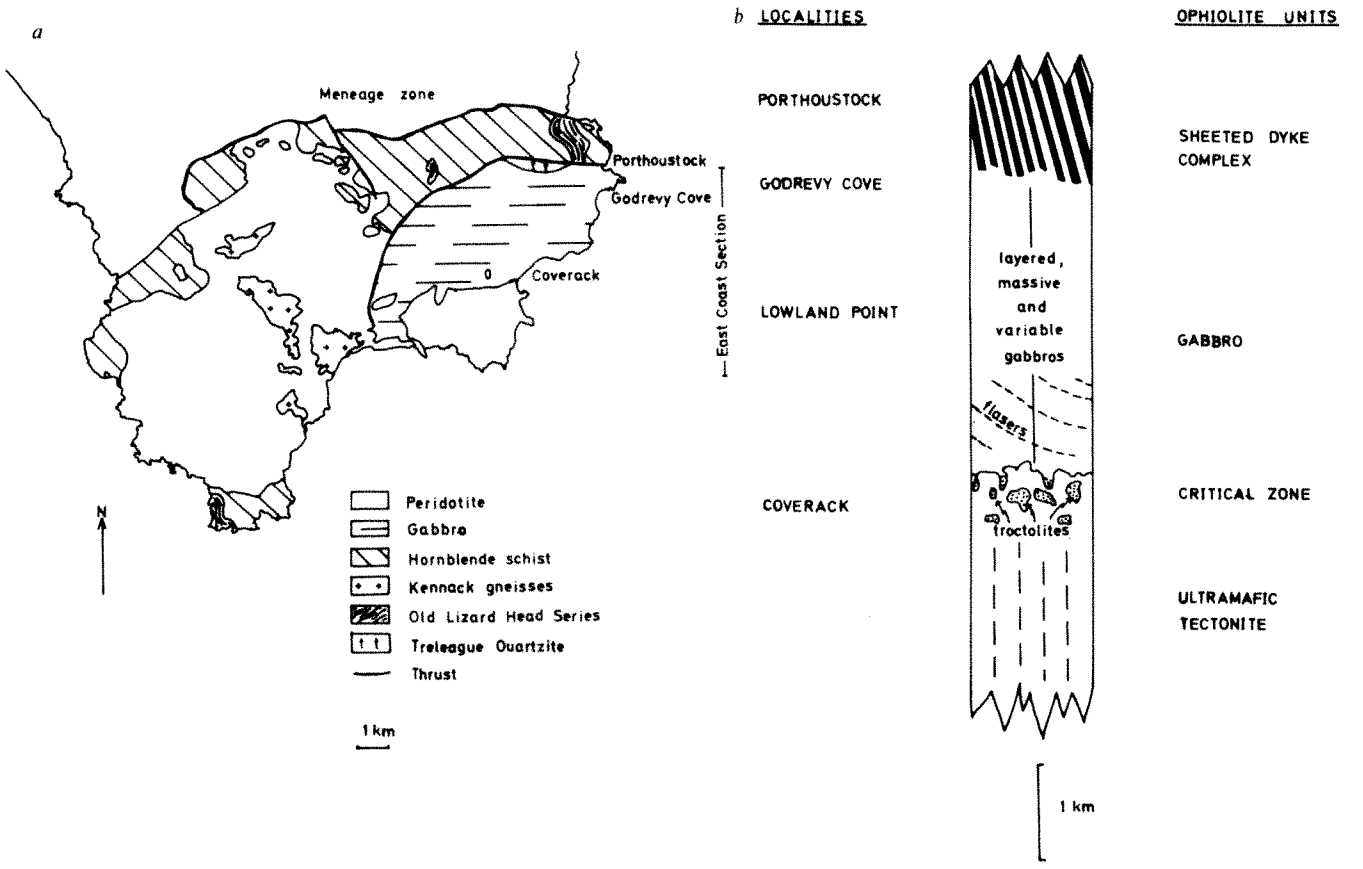

Fig. 1 *a*, Simplified geological map of the Lizard complex. *b*, Schematic section of the east coast section and a comparison with an ophiolite succession.

Coverack in the south is a broad zone in which olivine-rich gabbroic and ultramafic rocks ('troctolites') ranging from dunites to olivine gabbros, are complexly interdigitated with peridotite. The troctolites are considered to be the first (and therefore olivine-rich) cumulates which separated from the gabbroic magma, which overlay the peridotite and which were subsequently deformed and partially remobilised, resulting in the inclusion of blocks of peridotite. A possibly slow rate of removal of melt from the peridotite may have resulted in the precipitation of troctolites in pods within the peridotite. Partial-melt textures in the host peridotite are encountered locally in this zone. Rudely-banded lherzolites and harzburgites containing little or no troctolite outcrop further to the south.

The similarity in both the lithologies present and the order in which they occur to the rock succession encountered in an ophiolite sequence (Fig. 1*b*) is striking and considered to be sufficient evidence to accept this as a truncated ophiolite sequence. This interpretation is in complete contrast to that of Green[3] who considered the gabbro to form part of an *in situ* ring intrusion into peridotite.

Of prime importance to the proposed ophiolitic nature of the complex is the relationship between peridotite and gabbro; in ophiolites these are thought to have a parent–daughter relationship. Gabbro in the Lizard complex occurs only within peridotite and not in other lithologies—fortuitous if these two lighologies are not related. Examination of Green's lithological map and the author's field observations show that the gabbro is further restricted to the primary-type peridotite and does not occur in the recrystallised varieties except as isolated and deformed scraps. This implies that the association of peridotite and gabbro existed before their juxtapositioning with the surrounding hornblende schists (the event in which some of the peridotite was recrystallised), a feature common to many other ophiolites. Partial-melt textures at Coverack and locally elsewhere involve gabbroic veins with gradational boundaries against the surrounding peridotite. These support a genetic relationship, which is supported further by the relative rare earth contents of the two lithologies[11]. Thus the proposal for the ophiolitic nature of the complex is strengthened.

The remainder of the Lizard complex, which contains very little gabbro is considered to be the peridotite component of the ophiolite sequence together with the underlying metabasic and metasedimentary sub-ophiolitic rocks (the hornblende schists, the Old Lizard Head series rocks and the Kennack gneisses). These lithologies will be reported elsewhere but the salient points are noted here. Two varieties of hornblende schist were distinguished by Flett[12] and subsequently by Green[3]—the Traboe and the Landewednack hornblende schists. The Traboe variety occurs near the peridotite and was considered to be the upper amphibolite and granulite facies derivative of the amphibolite-grade Landewednack variety, the agent of metamorphism being the intrusive peridotite. Chemical data, however[13], show that the two groups are chemically distinct and cannot therefore be metamorphic equivalents. The Traboe schists are chemically more 'primitive' than the Landewednack schists. Both the chemical and field evidence support derivation of the Traboe schists from dominantly intrusive and cumulate gabbroic rocks and the Landewednack schists from dominantly intrusive and extrusive basaltic rocks. All are tholeiitic and those which were derived from basaltic protoliths have an oceanic chemistry (Fig. 2). It is proposed that the hornblende schists were derived by deformation of an ophiolite sequence adjacent to and chemically slightly different from that of the east coast section. The transition from the Landewednack variety to the Traboe variety reflects the original transition from the extrusive basaltic to the cumulate gabbroic portion of the ophiolite. True prograde metamorphic sequences are thought to be restricted to those schists below the peridotite from Kennack southwards to Landewednack. Much of Green's prograde metamorphic sequence is thought to be a feature of retrogression.

The Kennack gneisses show abundant evidence of formation by an *in situ* segregation process, in contrast to the arteritic origin proposed by Green, although this is undoubtedly locally true. Detailed petrographic evidence together with the

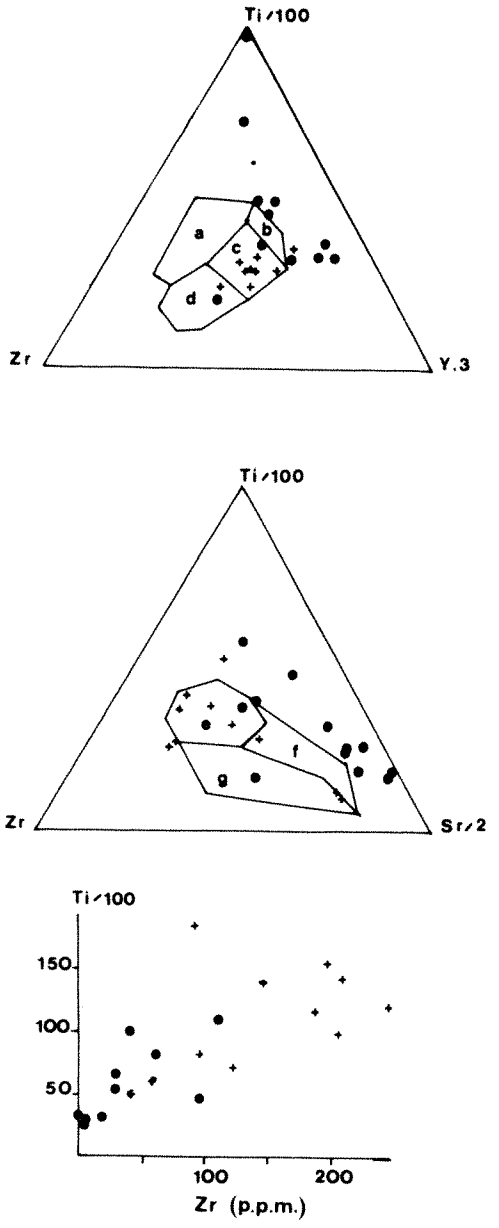

Fig. 2 Geochemistry of the hornblende schists. +, Landewednack; ●, Traboe. Field divisions from Pearce and Cann[28]: a, within place basalts; b, c, low potassium tholeiites; c, ocean floor basalts; c, d, calc alkaline basalts; e, ocean floor basalts; f, island arc basalts; g, Calc alkaline basalts. The large scatter of data points of the Traboe is a direct result of their low incompatible element contents resulting from their probable derivation from cumulative gabbros.

chemistry of the acid and basic portions suggest that the most likely process was one of partial anatexis of sediments and volcanics. The spatial restriction of the gneisses and the parallelism of the banding to the margin (base) of the peridotite suggests that this was achieved during overriding of the hot peridotite body. The deformation during assembly of the Lizard complex is thought to have resulted in the recrystallisation of the margins of the peridotite to lower pressure assemblages (the recrystallised anhydrous and hydrous varieties of Green[3]).

The question remains, however, as to whether this ophiolite is a fragment of oceanic crust, as is commonly proposed for many other ophiolites[14–17]. The complete absence of rocks of continental affinities within the east coast section is thought to be strong evidence in support of an oceanic origin for the complex. Deformation of the gabbroic cumulates occurred throughout their cooling history and ranged from slumping of unconsolidated cumulates through crystal-mush deformation in a direction subparallel to the layering to the formation of flaser gabbros and finally to brittle faulting. Flaser gabbro zones are concentrated in the south of the gabbro in the lower part of the original cumulate pile and represent low-angled slides developed under amphibolite-facies conditions during cooling of the gabbro. The above, combined with the large degree of crustal extension indicated by the dykes of the dyke complex, demonstrate that crystallisation of the complex occurred in a dominantly tensional and tectonically unstable environment. This is certainly consistent with an origin of the complex at a constructive plate margin. Chemical analyses of the basaltic dykes (ref. 13 and G.A.K., in preparation) indicate a close similarity in both major and trace-element compositions to oceanic tholeiites (Fig. 3). The gabbroic cumulates have tholeitic affinities and are also thought to have been derived from an oceanic tholeiite magma. Geochemical evidence therefore also supports an interpretation of the Lizard ophiolite as a fragment of oceanic crust. If present models for the generation of oceanic crust are correct[18–20], then the gabbroic cumulates and dykes should be derived from the same primary magma. The geochemistry of the dykes at Porthoustock and the gabbroic cumulates of the Lizard broadly support this proposal (Fig. 4), although these results are at variance with those of Floyd *et al.*[21].

The extrusive portion of the ophiolite sequence is absent south of the Lizard boundary thrust. However, pillow lavas occur within the Meneage crush zone, which is believed to be a

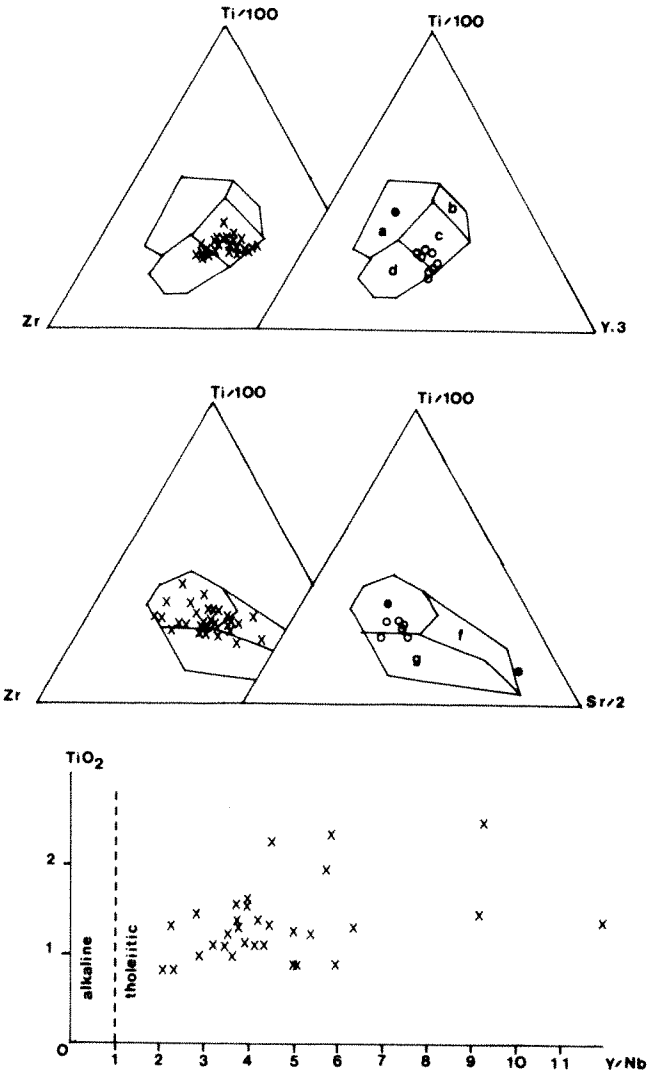

Fig. 3 Geochemistry of basaltic dykes (×) and lavas (○). ●, Average SW England tholeiite. Fields as for Fig. 2. Alkaline–tholeiite discriminant diagram from Floyd and Winchester[29].

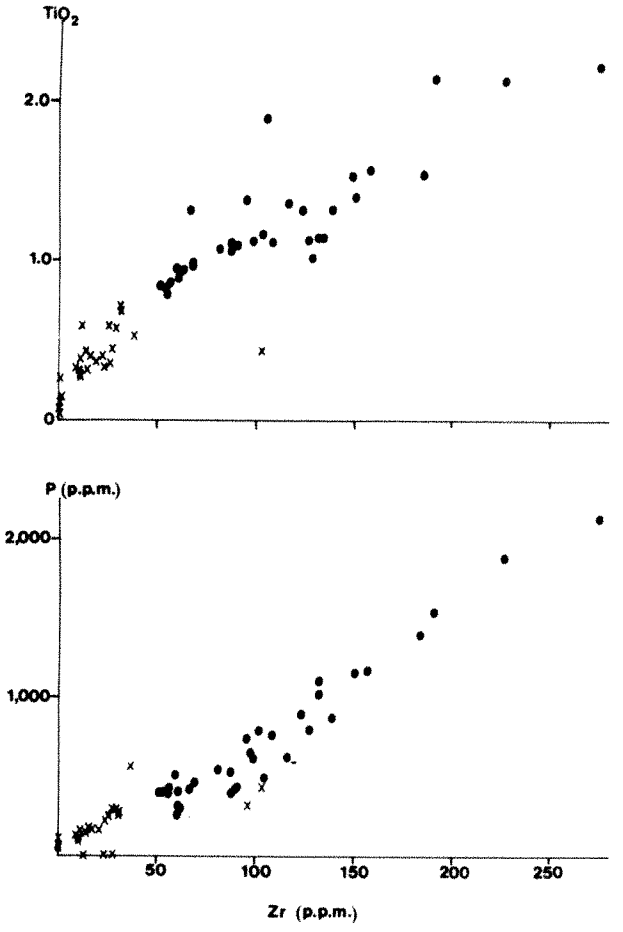

Fig. 4 Interrelationship of trace-element contents of dykes (●) and cumulate gabbros (×). Approximately straight-line trend with gabbros plotting at low concentrations supports a cogenetic relationship.

melange produced beneath and in front of the Lizard ophiolite during its emplacement. The chemistry of the contained lavas is closely allied to rocks of the Lizard complex (Fig. 3) and quite different from the remaining greenstones of South-west England[1,13,22]. It is therefore thought possible that these lavas are part of the extrusive portion of the Lizard ophiolite or the surrounding oceanic crust which was incorporated into an olistostrome ahead of the ophiolite during its emplacement, and which were subsequently overridden.

The acceptance of the Lizard complex as obducted oceanic crust has important implications for the geological history of SW England. Thus models such as that of Floyd[23] in which SW England was never underlain by oceanic crust are thought to be, in part at least, incorrect. However, I would support Floyd's interpretation of the geochemistry of other SW England greenstones in suggesting that the ocean crust did not extend anywhere north of the Lizard boundary thrust or its extension eastwards. Equally, therefore, the models of Johnson[24], Burret[25], Laurent[26] and Burne[27] are thought to be incorrect in suggesting that all of SW England was underlain by oceanic crust. A knowledge of the age of generation and emplacement of this oceanic crust is important in the development of geotectonic models for this region. It is thought that the ages of up to 403 Myr (late Silurian) obtained from the dykes of the dyke complex[4] most closely approximate the age of generation. Dates obtained from the gabbro would also be definitive (work on this is in progress). The concentration of ages determined from the hornblende schists and the Kennack gneisses (370–390 Myr)[2] are thought to date the assembly and beginning of emplacement of the ophiolite. The short time between the generation and emplacement of the complex is a feature common to many ophiolites.

In conclusion it is thought that many features of the Lizard complex do not support an origin by diapiric intrusion of peridotite into continental crust. The geological and geochemical features are consistent with formation as part of late Silurian (?) oceanic crust followed by emplacement of the resulting ophiolite sequence over the continental margin of SW England in early Devonian times.

This work was undertaken at Southampton University whilst I was in receipt of a NERC research grant.

High sediment yields from major rivers of the Western Southern Alps, New Zealand

George A. Griffiths

Water and Soil Division, Ministry of Works and Development, PO Box 1479, Christchurch, New Zealand

Suspended sediment yields have been determined by combining suspended sediment rating relationships with water flow records for gauged rivers of South Island, New Zealand. Rivers draining the Western Southern Alps have specific annual yields about 10 times higher than world average rates for mountainous areas. Their short steep catchments, rising in elevation from near sea level to over 3,000 m, support dense unmodified podocarp hardwood and beech forests below 1,000 m. The drainage basins are virtually undisturbed. A simple positive power law relationship between specific annual suspended sediment yields and the extremely high mean annual rainfalls explains almost all the variance in yield for catchments of the western region. This simple law may also hold for undisturbed catchments having a temperate maritime climate, in other areas of the world.

Suspended sediment yields (Table 1) were calculated by integrating suspended sediment rating relationships with continuous flow records of the rivers. These rating relationships are of the form

$$C = aQ^b$$

where C is the suspended sediment concentration in kg m^{-3} and Q is the water discharge in m^3 s^{-1}. Exponents are similar for all major rivers ($b = 2.2$ to 2.7); coefficients vary through several orders of magnitude ($a = 1.80 \times 10^{-3}$ to 1.87×10^{-5}) partly reflecting the wide variation in catchment areas. The range of suspended sediment concentration values, displayed in Fig. 2 for two typical rivers, is not exceptional. Stage discharge ratings on the unstable channels are defined by a regular gauging

* Minor river.

programme. Unlike water flow gaugings, concentration measurements have mostly been made during floods having peak discharges less than the mean annual flood but ~75% of the sediment is transported by these lower peak discharge, higher frequency events[1].

The algorithm used for the computer calculation of yield was

$$G = (1/1000AT) \sum_{i=1}^{n} 0.25(C_i + C_{i+1})(Q_i + Q_{i+1})\,\Delta t$$

in which A is the catchment area in km^2, T is the duration of the water flow record in years, n is the number of observations, i is a summation integer and G is the specific suspended sediment yield in tonnes km^{-2} yr^{-1}. At a gauging station the water level is recorded every 900 s and thus Q at the same interval may be derived from a flow rating. It was found to be sufficiently accurate, however, to use a value of 3,600 s for Δt in the above algorithm. It has been suggested[2] that the absolute errors associated with calculation of sediment yield by methods similar to the above, could be as high as +60% for annual yields. Unfortunately, absolute errors for the data of Table 1 cannot be assessed owing to the absence of measurements made by an alternative precise procedure. The regional consistency of yields demonstrated in Fig. 3 does suggest, however, that the relative error between rivers is small.

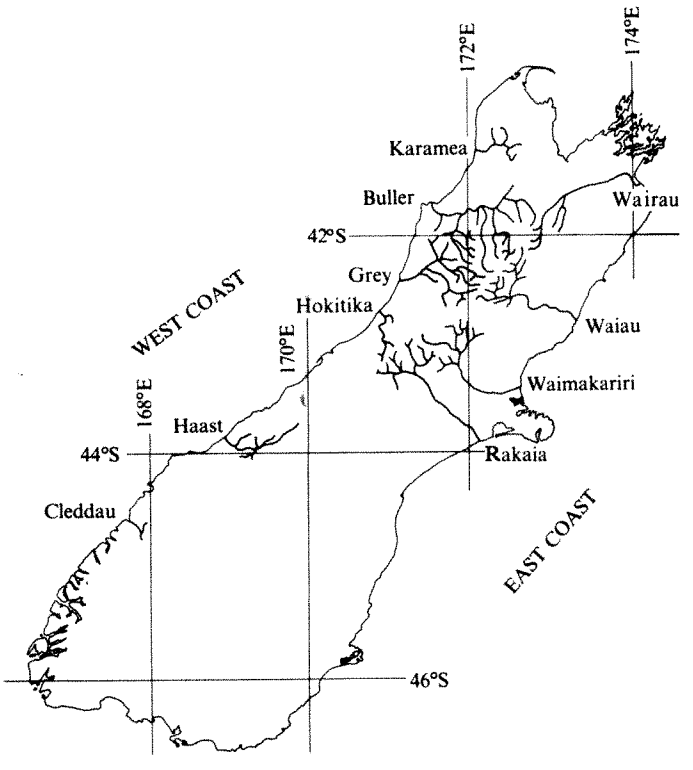

Fig. 1 Map of South Island, New Zealand, showing the location of major rivers gauged for suspended sediment. Other rivers were either not measured or have sediment storage basins (lakes) upstream of gauging stations.

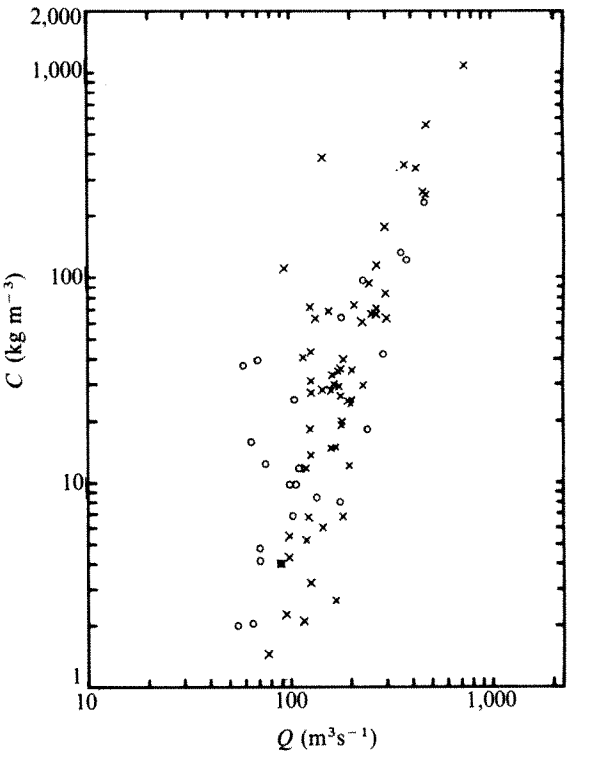

Fig. 2 Suspended sediment concentration, C plotted against water discharge, Q, for the Rakaia River (×) and the Haast River (○).

Catchments of very different geology, for example, that of the Rakaia River on well indurated sandstone and that of the Haast River on fissile schist, have nearly identical suspended sediment rating relationships (Fig. 2). Furthermore, West Coast rivers (Fig. 1) are steeper, have coarser gravel beds and shorter braided lengths than others in South Island, as they occupy gorges for most of their extent.

Specific yields calculated for East Coast rivers (Table 1) are in general agreement with earlier crude estimates (S. Thompson and J. Adams, personal communication). The world average denudation rate for mountainous terrain is estimated[3] to be 1,300 tonnes km^{-2} yr^{-1}. Rates for East Coast catchments lie close to this figure. (Bedload and dissolved load is not included in Table 1, but the few measurements available suggest that these components rarely exceed 10% of the total load[1].)

There is a spectacular rise in specific water and sediment yields and in mean annual rainfall south of the Grey River. The specific sediment yield of the Hokitika River is enormous: it is 2.4 times higher than that of the Ching River in China, quoted[4] as having the largest measured specific yield of major rivers of the world.

A linear multiple regression analysis between sediment yield as the dependent variable and independent variables, including catchment area, mean annual rainfall, mean annual discharge, mean annual flood, 10 yr recurrence interval flood, mean annual runoff, mean annual flood runoff, 10 yr recurrence interval flood runoff, mean basin elevation above sea level, river channel

length, mean catchment slope and percentage forest cover—for West Coast catchments (Table 1) indicated that 95% of the variance in suspended sediment yield for the region is accounted for by mean annual rainfall (Fig. 3). All variables used in the analysis were logarithmically transformed. Geology varies widely from granite to indurated sandstone and mudstone to fissile schist on West Coast and, as implied earlier, variations are apparently of little significance in suspended sediment production.

Current analysis may, however, reveal the relative influence of further parameters.

The simple positive power law relationship between suspended sediment yield and rainfall, P, defined in Fig. 3 by

$$G = 9.02 \times 10^{-11} P^{3.65}$$

confirms previous work which has pointed to this positive trend[5-10].

In terms of mean annual runoff, R (mm) the relationship is

$$G = 3.51 \times 10^{-8} R^{3.00}$$

which explains 93% of the variance in yield and reflects, in part, the poor water storage capacities of the catchments involved.

The yield/rainfall relationship of Fig. 3 may be typical of other very high rainfall areas such as parts of the Himalayas[11,12], New Guinea[13,14], Japan[15], Java[16] and Taiwan[17] where large specific yields have been reported. Taiwan is of particular interest, for within the hardwood forest covered, steep Central Range the average specific suspended sediment yield is 13,000 tonnes km^{-2} yr^{-1} which is similar to the average value (14,000 tonnes km^{-2} yr^{-1}) for rivers south of the Hokitika River, South Island. Moreover, gross rainfall values[18] exceed 5,000 mm for the higher yielding Taiwan catchments and are comparable to the values of 6,000–7,000 mm for catchments south of the Hokitika River.

The highest specific yield in Taiwan, measured on a minor river[17], is 31,700 tonnes km^{-2} yr^{-1} perhaps the highest known value in the world. But if the relationship in Fig. 3 is valid regionally, then in minor south West Coast drainage basins, where mean annual rainfalls surpass 10,000 mm, yields above 36,000 tonnes km^{-2} yr^{-1} probably exist.

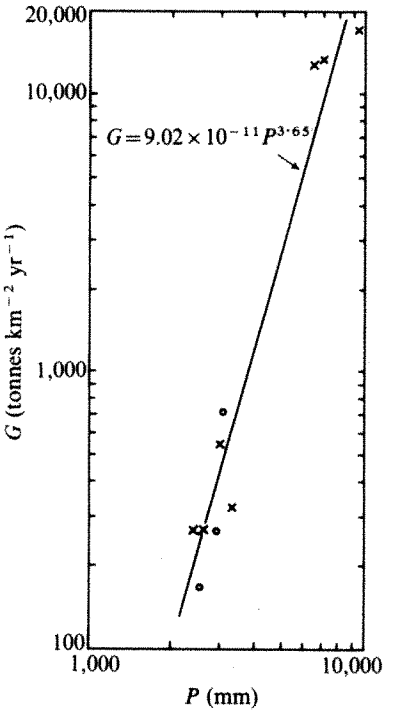

Fig. 3 Mean annual specific suspended sediment yield, G, plotted against catchment mean annual rainfall, P, for major rivers (×) and minor rivers (○) of the Western Southern Alps, New Zealand.

Predictions of suspended sediment yield as a function of precipitation in semi-arid or arid[5,9], subhumid[7,10], and tropical[5,7], conditions have been given elsewhere. None of these relationships apply to the West Coast region where temperate, maritime conditions exist. In such a climate, for undisturbed catchments, a simple power law expression between yield and rainfall may provide useful estimates of specific suspended sediment yields.

I thank D. Hewson and Dr R. Ibbitt for assistance with data analysis and Dr M. McSaveney for discussions. The support of the National Water and Soil Conservation Organisation, responsible for the data collection, is acknowledged.

Response of deep-sea benthonic Foraminifera to development of the psychrosphere near the Eocene/Oligocene boundary

Bruce H. Corliss

Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543

A dominant feature of present-day thermohaline circulation in oceans is the production of cold Antarctic Bottom Water (AABW) in the Weddell and Ross Seas and along the continental margin off Antarctica. The cold, dense AABW formed at or near the surface sinks to abyssal depths and travels throughout the ocean basins. AABW circulation was suggested to have begun near the Eocene/Oligocene boundary with the development of the psychrosphere (lower cold layer of a two-layer ocean with temperatures <10 °C) inferred from ostracode faunal data[1] and oxygen isotopic evidence from closely-spaced samples in DSDP site 277 (ref. 2). Previous studies suggested that the temperature change associated with the development of the psychrosphere caused a crisis for deep-sea ostrocodes[1] and deep-sea benthonic Foraminifera[3]. I consider here the response of benthonic Foraminifera to the development of the psychrosphere.

Benthonic Foraminifera in 15 closely-spaced sediment samples from DSDP site 277 have been examined. Comparison of the faunal data and the oxygen isotopic record reveals that the temperature drop coincides with a pronounced reduction of the frequency of *Epistominella umbonifera*. Few other faunal changes (first or last occurrences) are recorded at the time of the development of the psychrosphere, although 16 faunal changes occurred before and six occurred after the isotopic event. Taxa which exhibit first and last occurrences are all rare forms. I suggest that the psychrosphere may have developed gradually during the middle–late Eocene, culminating in a rapid temperature drop near the Eocene//Oligocene boundary.

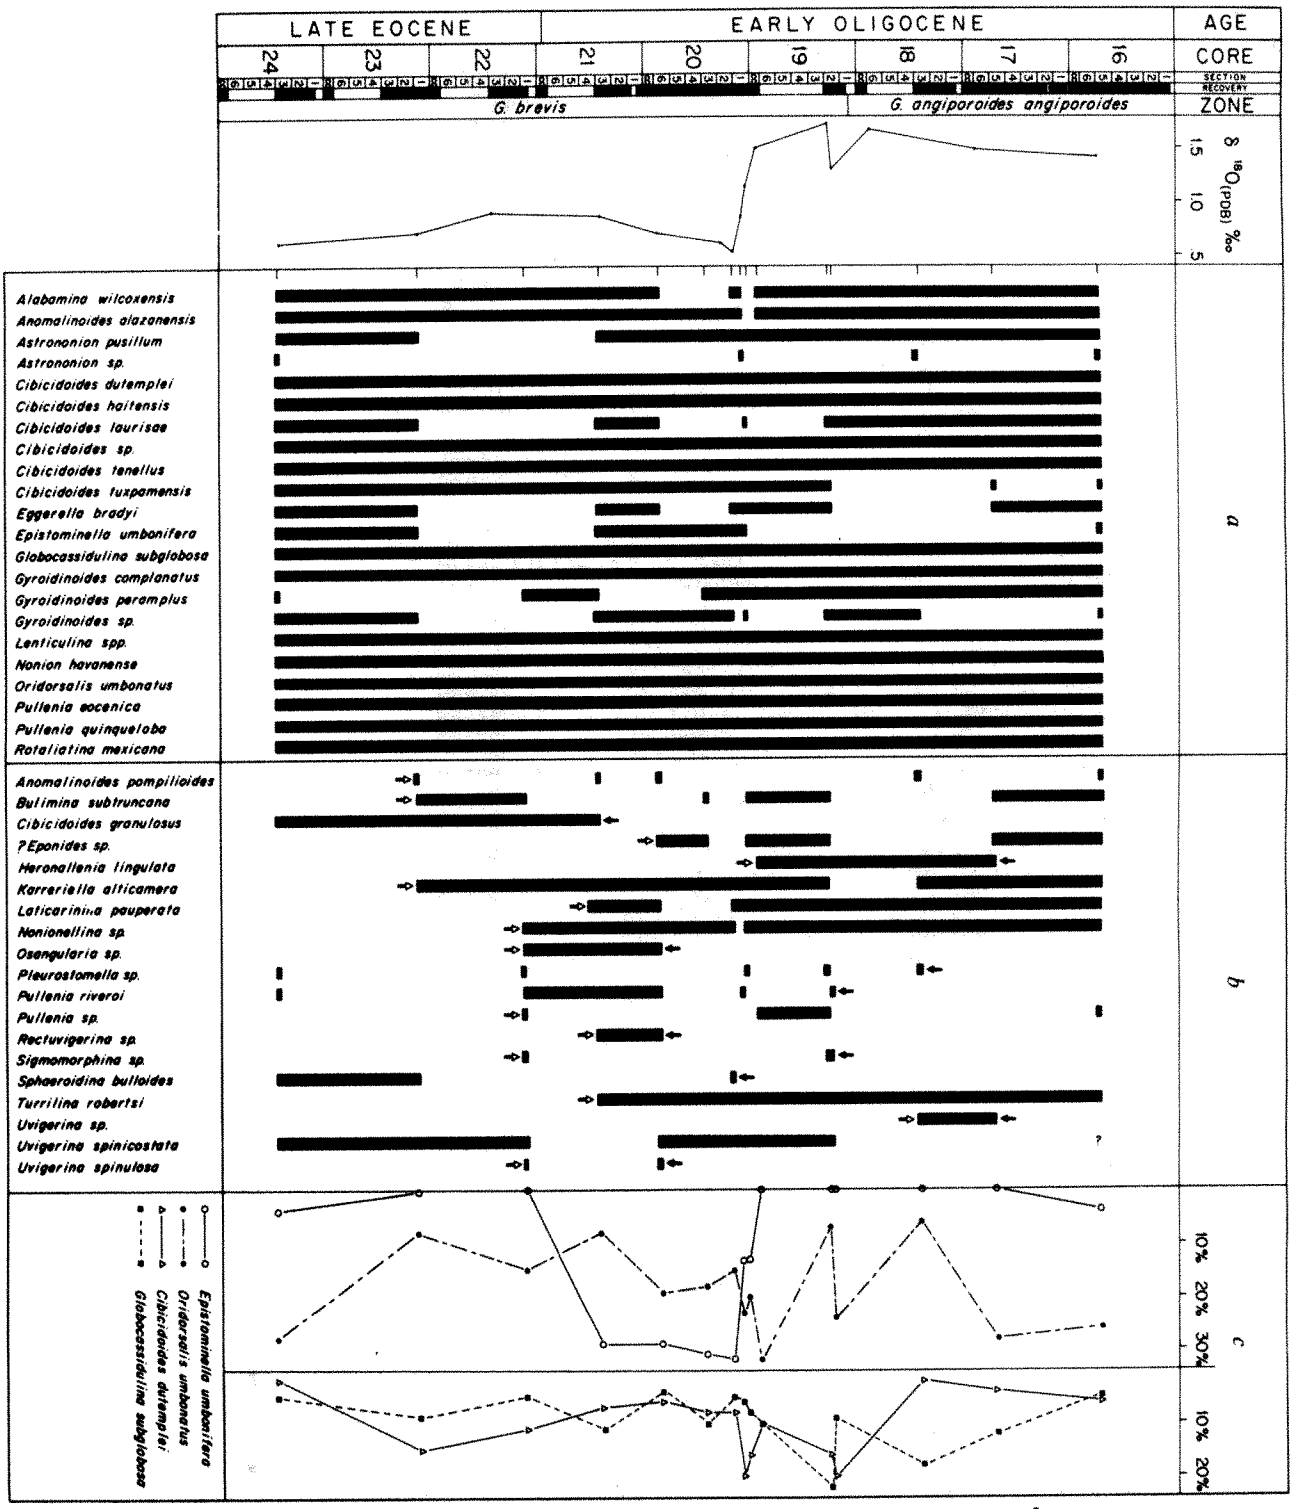

Fig. 1 Summary of benthonic foraminiferal biostratigraphic data from DSDP site 277. The inferred age[2], core recovery, planktonic foraminiferal zones[9], and isotopic curve based on mixed benthonic foraminifera[2] are shown left, with the tick marks indicating the samples examined for the benthonic foraminiferal analysis. Biostratigraphic ranges of 41 taxa are shown: *a*, taxa that lack first or last occurrences in the sequence; *b*, taxa that exhibit first or last occurrences. First appearances are marked by open arrows, and last occurrences are marked by solid arrows. *c*, Quantitative data of four dominant benthonic foraminiferal species.

DSDP site 277 is located on the Campbell Plateau (52°13.43′ S, 160°11.48′ E, 1,222 m) in sub-Antarctic waters south of New Zealand in the Southern Ocean. The sequence in site 277 consists of continuously cored foraminiferal-rich calcareous sediments[4]. The Campbell Plateau at 38 Myr was at about palaeolatitude 65 °S (ref. 5).

The oxygen isotope curve based on mixed benthonic Foraminifera for the late Eocene–early Oligocene (Fig. 1) is assumed to reflect temperature variation of the bottom waters[2], as the Antarctic continent is considered to have been essentially ice-free during the Eocene and Oligocene[6]. A reduction in bottom-water temperatures of about 5 °C was recorded in the earliest Oligocene. It has been suggested that the development of the psychrosphere resulted from this temperature change, reflecting a decrease in Antarctic surface water temperature to freezing, the production of the first extensive sea ice and the onset of cold bottom-water production[2]. The initiation of vigorous bottom-water circulation is thought to have caused widespread erosion of sediments, increased calcium carbonate dissolution in some areas, and caused a precipitous drop in the calcium carbonate compensation depth in other areas[2].

Oxygen isotope analysis of monospecific samples of the benthonic foraminifer *Oridorsalis umbonatus* in this section was recently carried out, and the temperature drop seems to be about 4 °C, (L. Keigwin, personal communication) rather than 4–5 °C as previously thought[2], but this drop is still significant. The exact stratigraphic position of core 19 samples relative to core 20 is unknown because of incomplete core recovery, and the rate of temperature decrease cannot be precisely determined, although a rapid reduction within 100,000 yr has been suggested[2].

Species frequencies of four dominant taxa, *C. dutemplei*, *E. umbonifera*, *G. subglobosa* and *O. umbonatus* are shown in Fig. 1*c*. The inferred temperature drop did not affect the relative abundance of three of these species. In contrast, the inferred temperature change seems to have had a pronounced effect on the relative abundance of *E. umbonifera*. This species is the dominant (29–32%) taxa preceding the isotopic event. A rapid decrease in *E. umbonifera* abundance parallels the isotopic curve during the isotopic change. *E. umbonifera* is not present in cores 19–17, and appears again in core 16 (4%). The water-mass event seems to have affected the relative abundance of this species and changed the composition of the assemblage.

Sixteen faunal events occurred before and six after the isotopic event. Using approximate sedimentation rates of 2.2 cm per 1,000 yr for cores 16–21 and 0.5 cm per 1,000 yr for cores 22–24 (ref. 4), the time interval between cores 16 and 20 is about 1.5 Myr, and the interval between cores 20 and 24 is about 5.5 Myr. The interval from cores 20 to 24 is a compressed section relative to cores 16–19, and may explain the greater number of faunal events before the isotopic event.

Only two faunal changes coincided with the development of the psychrosphere. The faunal changes preceding and subsequent to the isotopic change appear to have occurred gradually. This general faunal pattern is observed in other sequences in the Pacific[3] and Atlantic[7,8], where faunal changes are found throughout the late Eocene and early Oligocene.

The development of the psychrosphere in the deep sea created a new physicochemical environment, one of the most widespread in the Cenozoic. The occupation of this niche by new taxa would have either resulted from the migration of taxa into the psychrosphere or from the evolution within the psychrosphere of new taxa. The data from site 277 and from the Pacific[3] and Atlantic[7,8] suggest that the faunal turnover close to the inferred temperature change was limited to a few taxa. Following the development of the psychrosphere, the Foraminifera gradually changed during an interval of several million years until a stable assemblage was established. Some forms were unaffected, being present during both the Eocene and Oligocene. The lack of faunal change occurring immediately after the bottom-water temperature drop suggests that the species must have had fairly wide environmental tolerances, and stenotopic species such as those found at present in the deep sea evolved sometime after the development of the psychrosphere. The stenotopic psychrospheric assemblage probably took a long time to develop, perhaps in response to relatively constant environmental conditions in the deep sea. This interpretation is based on the assumption that the isotopic event reflects a temperature decrease as previously suggested[2,6], and not a change in the oceanic isotopic composition. No faunal change would be expected if the isotopic event reflected a change in the oceanic isotopic composition.

The isotopic data at site 277 show a pronounced cooling in bottom waters occurring in the mid–early Eocene followed by a steady decrease in bottom temperatures to the Eocene/Oligocene boundary[6] where the sharp temperature drop is observed. The decrease in bottom temperatures during the middle–late Eocene may reflect the initial and gradual development of the psychrosphere, with the isotopic change near the Eocene/Oligocene boundary representing part of this development and caused by some event that marks a threshold in Southern Ocean palaeocirculation. If the psychrosphere did develop gradually, this would account for the gradual changes in benthonic Foraminifera observed during the late Eocene before the isotopic drop near the Eocene/Oligocene boundary.

I thank J. P. Kennett for helpful suggestions and financial support, W. A. Berggren, Felix Gradstein, Lloyd Keigwin, T. C. Moore, Jr. and Robert C. Thunell for discussions; Leonard Tjalsma for discussions on the benthonic foraminiferal taxonomy, Charles D. Hollister for partial financial support, Edna Coneybear for drafting assistance and Mary Berry for typing. The research was supported by NSF grant DPP-77-06687 (Division of Polar Programs) while at the University of Rhode Island and NSF grant DPP-78-21105 (Division of Polar Programs) at Woods Hole Oceanographic Institution.

Late Eocene of Burma yields earliest anthropoid primate, *Pondaungia cotteri*

Ba Maw*, Russell L. Ciochon† & Donald E. Savage‡

* Department of Geology, Mandalay Arts and Sciences University, Mandalay, Union of Burma
† Department of Sociology and Anthropology, University of North Carolina, Charlotte, North Carolina 28223
‡ Department and Museum of Paleontology, University of California, Berkeley, California 94720

In April 1978, a fragment of a primate lower jaw containing the second and third molar teeth was found in late Eocene exposures of the Pondaung Hills about 1 mile north-west of Mogaung village in northwestern Central Burma. This approximately 40-Myr-old specimen is the first fossil primate found in Burma since the fragmentary remains of the controversial earliest anthropoids *Pondaungia cotteri* Pilgrim[1] and *Amphipithecus mogaungensis* Colbert[2] were recovered more than 50 yr ago. The jaw described here is believed to represent further evidence of *P. cotteri*. Its recovery from undoubted late Eocene exposures coupled with its salient higher primate characters and excellent state of preservation provides the opportunity to substantiate further that the Pondaung primates of Burma are the earliest known record of the Anthropoidea.

The new specimen was recovered with a characteristic late Eocene fauna, including fishes, turtles, sebecid and other crocodilians, brontotheres, amynodont rhinoceroses and anthracotheres, as float on greyish yellow, grey and red claystones. These claystones comprise the uppermost 100 feet of the Pondaung Formation near Mogaung village. Locally, the upper beds of the Pondaung Formation are conformably overlain by a southerly emanating marine incursion called the Yaw Formation, containing a rich foraminiferal and molluscan fauna. This fauna has been correlated with the Ludian (=Bartonian) European marine stage[3–7] which dates the underlying Pondaung fauna as late Eocene, approximately 40 Myr BP.

The jaw fragment (Fig. 1) is part of a right dentary with M_{2-3}, University of California Museum of Paleontology (UCMP) No. 120377, from UCMP locality V78090, Mogaung Northwest. The animal was about the size of the larger species of living gibbons and probably attained a size and weight (based in part on M_2 length correlation[8]) equal to or greater than that suggested for *Aegyptopithecus zeuxis* Simons or *Adapis magnus* Filhol.

We provisionally assign UCMP 120377 to the Anthropoidea and refer it to *Pondaungia cotteri*. Although the fragmentary nature and chemically eroded enamel surfaces of the holotype of *P. cotteri*[1] (Geological Survey of India, GDI D201-203) make comparisons with UCMP 120377 difficult, we feel the referral is justifiable on both morphological and metrical grounds.

Order Primates Linnaeus, 1758
Suborder Haplorhini Pocock, 1918
Hyporder Anthropoidea Mivart, 1864
?Infraorder Catarrhini E. Geoffroy, 1812
Genus *Pondaungia* Pilgrim, 1927
Pondaungia cotteri Pilgrim, 1927

Revised diagnosis: Gibbon-sized primates with bunodont tetracuspate upper molars having weak lingual cingula. The bunodont hexacuspate lower molars have only obscure and incomplete ectocingulids. M_{2-3} with many accessory cuspules and low ridges effecting a strongly corrugated ('pustulate') occlusal surface.
Range: Two localities in the Pondaung Formation, Late Eocene, Central Burma.
Measurements: As given in Table 1.

Table 1 Measurements (mm) of GDI D201 and UCMP 120377

	GDI D201	UCMP 120377
Depth of jaw below anterior root of M_2, external (buccal) surface	11.9	16.3
Depth of jaw below anterior root of M_2, internal (lingual) surface	12.3	17.4
Maximum anteroposterior dimension of crown of M_2	6.1	7.1
Maximum transverse dimension of crown of M_2 (the trigonid is less than 0.1 mm wider than the talonid)	5.9	6.7
Maximum anteroposterior dimension of M_3	7.3	8.3
Maximum transverse dimension of crown of M_3 (= width of trigonid)	5.2	6.0

Immediately recognisable characters of the new specimen are its great jaw depth in relation to molar crown height and its relatively thick mandibular corpus. Nearly all anthropoid primates uniquely share these proportions, which are probably related to increased stresses placed on the mandible during mastication[9,10], and their presence in *Pondaungia* is evidence for its inclusion in the higher primates. Simons[11] made a similar decision regarding *Amphipithecus*. Figure 2 compares the new specimen with *Amphipithecus* (AMNH 32520) and *Homo*. Furthermore, jaw depth in UCMP 120377 is proportionately greater than in the holotype of *Pondaungia* (see Table 1) which could indicate a juvenile status for the type (P. D. Gingerich, personal communication).

M_2 and M_3 of UCMP 120377 are large, bunodont and multicuspate. M_2 is a rectangle with rounded corners in occlusal outline. Unlike most adapines, notharctines and omomyids, the maximum transverse widths of the trigonid and talonid are about equal. In most living and fossil lower primates the talonid is noticeably wider than the trigonid. The trigonid of UCMP 120377 is only slightly higher than the talonid and there is a prominent, closed, highly corrugated talonid basin. This bunodont tooth has a complicated enamel surface with many accessory low cuspules and ridges with no primary trend. Nevertheless, the six principal (and interpretatively primitive) cusps can be identified and delineated (Fig. 1); all are marginally placed. The strong paraconid lies anterolabiad and adjacent to the metaconid, and these two cusps form a twin-peaked crest at the anterolingual corner of the tooth. This arrangement is seen on the M_2 of some omomyids such as *Altanius* Dashzeveg and McKenna[12] and *Tetonoides* Gazin[13] and on some specimens of the early adapids such as *Pelycodus* Cope. The protoconid and hypoconid are, areally, the largest of the cusps and are evenly rounded (that is, symmetrically bunodont). The entoconid is also evenly rounded but smaller than the labial cusps. A faint cingulum lies anterolabiad to the protoconid; otherwise, the lateral faces of the crown of this tooth are smooth.

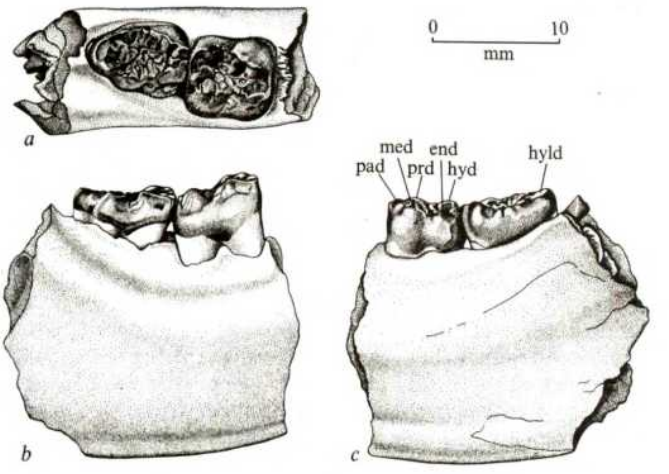

Fig. 1 *Pondaungia cotteri*, right dentary with M_{2-3}, UCMP 120377, from Mogaung Northwest, Central Burma. *a*, Occlusal view; *b*, labial view; *c*, lingual view. Pad = paraconid; end = entoconid; med = metaconid; hyd = hypoconid; prd = protoconid; hyld = hypoconulid.

On the posterior and lateral wall of the M_2 trigonid of *Pondaungia* there is a definable wear facet. This derived (Phase II) wear facet has been called facet 'X' by Kay[14] and facet 11 by Maier[15] and characterises all the living catarrhines and all known fossil catarrhines with the exception of *Oligopithecus*[14]. It has not been found in any Palaeogene lower primate and is absent from all living lower primates with the possible exception of some members of the Indriidae[15].

An area interpreted as a worn hypoconulid is a flat, faceted, transversely elongate eminence at the midline of the tooth, forming the posterior border of the central basin. Before wear, it may have been a twin-peaked cusp. Especially in its abraded state, it is much lower than the hypoconid and entoconid. The presence of a hypoconulid on M_2 is a feature which *Pondaungia* shares with the Fayum and later catarrhine primates (other than Cercopithecidae).

The trigonid cusps and basin of the M_3 are slightly higher than the talonid cusps and basin, as on M_2. Unlike the M_2, however, the trigonid basin of M_3 is separated from the talonid basin by a continuous high-elevation cristid from metaconid to protoconid. As might be expected from a consideration of the lower molars of other Eocene primates, the paraconid of M_3 is smaller, lower and less distinct from the metaconid than on M_2. The metaconid is clearly the highest cusp on M_3. Protoconid and hypoconid are very similar to their homologues on M_2 except that the hypoconid makes a prominent bulge on the labial face of the talonid of M_3, as it does in many other primates. Also, as on M_2, a faint and discontinuous cingulum lies labiad to the protoconid. No

other cingula are present. The talonid area is elongate posteriorly as in other early primates, and the massive, crescentic hypoconulid—well worn on this specimen—forms an elevated posterior border. The central one of three peaks on the lingual marginal ridge of the talonid basin is identified as the entoconid; it is small compared with the entoconid on M_2. The surface of the talonid basin of M_3 is even more intricately corrugated than on M_2. This dental configuration seems best adapted for crushing and grinding soft plant material and fruits.

UCMP 120377 is thus a mosaic of higher and lower primate characters, with the former more predominant and exemplifying the derived (apomorphic) condition. This new specimen is similar in size and general molar features to the early catarrhine *Aegyptopithecus* Simons[16] from the Oligocene of North Africa, but the conical molar hypoconulids and strong cingulid development in *Aegyptopithecus* coupled with the presence of molar paraconids in *Pondaungia* rule out any close relationship. When *Pondaungia* is compared with Fayum parapithecoids *Apidium* Osborn and *Parapithecus* Schlosser, the only marked similarities are the bunodonty and lack of cingulid development shared by *Apidium* and *Pondaungia*.

Comparisons with Eocene primates such as omomyoids or adapoids indicate that the lower-molar patterns of *Pondaungia* (and *Amphipithecus*) could be derived from certain species of *Pelycodus* Cope (Early Eocene, North America and Europe). Pilgrim[1] emphasised this in his description of the type of *Pondaungia*. Furthermore, the upper molars of *Pondaungia cotteri* complement this view, for they seem to have pseudohypocones in the notharctine manner[1]. The more crestiform lower molars of later notharctines in North America and of the adapines in Europe are too specialised (derived) to be considered ancestral, however. Kay[17] also notes that the well developed premetacristid on the M_2 of *Pondaungia* which links up with the paraconid to form a complete medial wall for the trigonid is a feature reminiscent of advanced omomyids and early anthropoids, and further suggests that such a trigonid organisation could rule out known European adapids from the ancestry of *Pondaungia*.

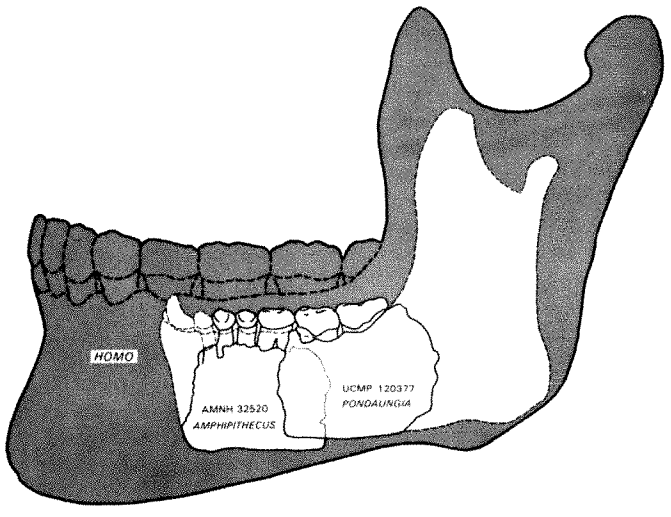

Fig. 2 Size and configuration of the jaw fragments of *Amphipithecus mogaungensis*, AMNH 32520 and *Pondaungia cotteri*, UCMP 120377, compared with *Homo sapiens*. Note how the two Pondaung primates exhibit the same relative jaw proportions as the higher primate *Homo*.

We believe that *Pondaungia* Pilgrim and *Amphipithecus* Colbert are two valid and separate co-existing genera of primates. We also believe that the new specimen of *Pondaungia* was probably a large male in the ancient population that included the type specimen of *P. cotteri* as the smaller females (see Table 1). This conclusion is supported by the differences in size of adult teeth of males and females documented by Swindler[18] for living primates whose overall size is about the same as *Pondaungia*.

We conclude that *P. cotteri* and *A. mogaungensis* were specialised as deep-jawed primates with bunodont cheek teeth, the former being characterised by corrugated enamel surfaces on its teeth, the latter by smooth enamel. Their anatomy indicates they were at or near the ancestry of the anthropoids, perhaps closest to the Catarrhini. Of course, it is possible that they represent a remarkable convergence towards early anthropoids of an adapoid or omomyoid stock. However, we feel that when the anatomical features of *Pondaungia* (and *Amphipithecus*) are considered in the light of their zoogeographic position and latest Eocene age they seem most likely to represent the earliest known record of the Anthropoidea.

Establishing the precise phylogenetic affinities of *Pondaungia* (and *Amphipithecus*) is difficult, in part because of the scarcity of material. As they are now known, both are too aberrant and specialised to be considered ancestral to any known catarrhine. Their characters, however, do not vitiate Szalay's conclusion[19,20] that *Amphipithecus* is an advanced early Tertiary lemuriform–an adapoid. Similarly, neither *Pondaungia* nor *Amphipithecus* falsify Gingerich's conviction (for example, see ref. 21) that adapoids were ancestral to the anthropoids. From another viewpoint, Delson[22] suggests that *Pondaungia* may represent one branch of an omomyid-derived lineage which entered eastern Asia from North America by way of the Bering land bridge; another branch may thence have crossed the Tethys Sea into Africa to give rise to the Fayum (and later) catarrhines. Other hypotheses must be considered, however, pending discovery of more complete fossils from Burma. As the Palaeogene mammalian record of southern Asia is still so poorly known, one might even guess that a primate radicle unrelated to plesiadapiform, adapoid or omomyoid lineages culminated in the late Eocene earliest anthropoids *Pondaungia* and *Amphipithecus*.

Resistance analysis of sulphur dioxide fluxes to *Vicia faba*

V. J. Black & M. H. Unsworth

Department of Physiology and Environmental Studies, University of Nottingham School of Agriculture, Sutton Bonington, Loughborough, UK

Before plants respond directly to a gaseous air pollutant, the gas must diffuse into the leaves through stomatal pores or through the cuticle. Some gases are also absorbed or adsorbed on the surface of leaves[1] and this flux elicits no direct plant response. In principle, responses to a pollutant may depend either on the rate at which the gas is absorbed, or on the total quantity absorbed over a period of time. In practice, workers have commonly related responses either to the gas concentration surrounding the plant or to the dose, defined as the product of the gas concentration and the duration of exposure[2]. Plants exposed in an environment where the pollutant flux to leaves is restricted because there is little air movement[3] or because stomata are partly closed, are regarded as having the same dose as plants absorbing the pollutant rapidly. Consequently the response to a specified dose depends strongly on the conditions of exposure[3]. We report here laboratory measurements of fluxes of sulphur dioxide to plants of the field bean, *Vicia faba* L. and relate the observed inhibition of net photosynthesis to this flux. Measured fluxes are analysed to show the several pathways for SO_2 into and on to leaves, and to demonstrate that the internal concentration of SO_2 in the bean leaves was close to zero.

To quantify relationships between concentrations, fluxes and sink strengths, it is convenient to treat the diffusive transfer of gaseous pollutants to plants as analogous to the flow of current in electrical circuits[4,5], a method commonly used in the analysis of water vapour and carbon dioxide fluxes[6,7]. A gaseous flux

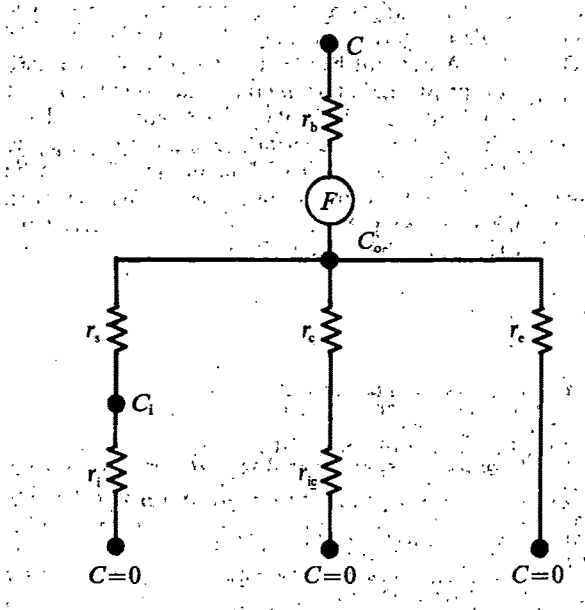

Fig. 1 A resistance analogue of SO_2 uptake by one surface of a leaf. The gas, at concentration C in the exposure chamber, is transferred through a boundary layer resistance r_b to the leaf surface where concentration is C_0. From the leaf surface there are three parallel pathways to sinks where $C = 0$: (1) through stomata, resistance r_s, into the substomatal cavity where concentration is C_i and subsequently through an internal resistance r_i; (2) through the cuticle, resistance r_c and through an internal resistance r_{ic}; (3) by external sorption on the cuticle and on materials on the leaf surface, resistance r_e.

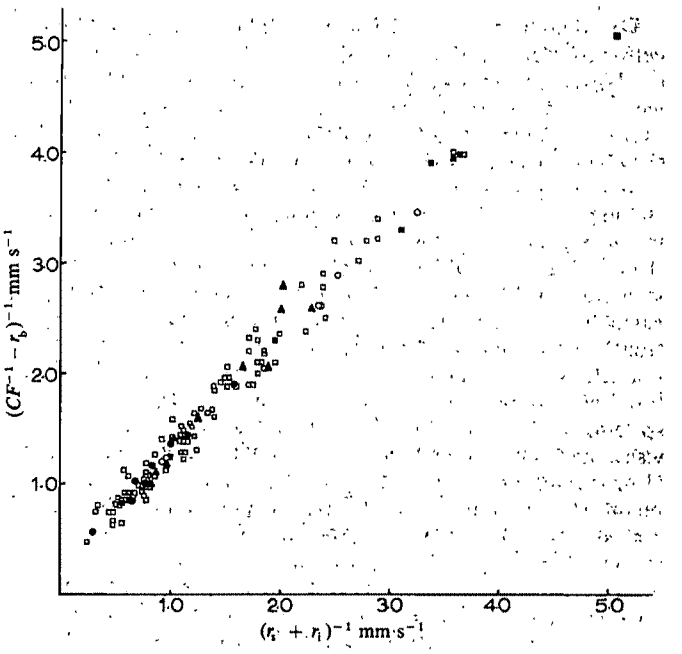

Fig. 2 Variation of $(CF^{-1}-r_b)^{-1}$ with $(r_s+r_i)^{-1}$ for SO_2 uptake by whole plants of *V. faba*. The ordinate is the deposition velocity for SO_2, (flux F/concentration C), modified for boundary layer resistance; the abscissa is the conductance resulting from stomatal (r_s) and internal (r_i) resistances acting in series. SO_2 concentrations: ○, 20 p.p.b.; ●, 40 p.p.b.; □, 75 p.p.b.; ■, 190 p.p.b.; ▲, 300 p.p.b.

(current) is driven by a difference in gas concentration (potential difference) and restricted by diffusive resistances of the leaf boundary layer, stomata and cuticle (resistance). Figure 1 shows a general resistance network for SO_2 uptake by a leaf, indicating parallel pathways through stomata, through cuticle and on to the leaf surface. Inside the sub-stomatal cavity, the SO_2 concentration has the value C_i and further diffusive resistances r_i and r_{ic} describe the restrictions to SO_2 transfer internally as a gas and eventually in solution to a sink where $C = 0$ by definition. In a similar way the resistance r_e limits the rate of surface deposition.

We now describe a method for determining some of the resistances in Fig. 1 from measurements of SO_2 and water vapour fluxes. From Fig. 1, two expressions may be written for the total SO_2 flux density F:

$$F = (C - C_0)/r_b \qquad (1)$$

and

$$F = (C_0 - 0)/[(r_s + r_i)^{-1} + (r_c + r_{ic})^{-1} + (r_e)^{-1}]^{-1} \qquad (2)$$

using the usual laws for finding the resultant of resistances in parallel. Eliminating the surface concentration C_0 from equations (1) and (2) and rearranging terms leads to

$$(CF^{-1} - r_b)^{-1} = (r_s + r_i)^{-1} + [(r_c + r_{ic})^{-1} + r_e^{-1}] \qquad (3)$$

Several terms in equation (3) may be measured or derived. In exposure chambers or cuvettes, the flux density F of gas to unit area of a leaf or plant can be calculated by measuring the concentration difference of gas between inlet and outlet of the chamber and the gas flow rate[8]. The gas concentration C is easily measured. Values of boundary layer and stomatal resistances, r_b and r_s, for SO_2 transfer may be found from analyses of water vapour loss from real and model leaves, making allowances for differences in diffusivity between SO_2 and H_2O (refs 5, 9). The form of equation (3) shows that if measured values of $(CF^{-1} - r_b)^{-1}$ are plotted against $(r_s + r_i)^{-1}$, a straight line graph with slope unity and intercept $[(r_c + r_{ic})^{-1} + r_e^{-1}]$ should result. Because r_i is not known *a priori*, it must be estimated, assuming that it is independent of F and r_s, to obtain the best straight line from a set of measurements.

We measured fluxes of SO_2 to whole plants of *Vicia faba* cultivar Dylan exposed, when they had three pairs of leaflets, in a cubical chamber (side 0.5 m) described elsewhere[9]. The plants were in pots with the soil surface covered to prevent gas exchange. To minimise SO_2 uptake on chamber walls and pots, they were covered with polyvinyl fluoride film and allowances were made in analysing the results for small residual SO_2 fluxes to the film and uncovered plant stems. Simultaneous measurements of concentration differences of SO_2, H_2O and CO_2 across the chamber allowed fluxes of these gases to be determined and stomatal resistances and rates of net photosynthesis were calculated[9,10]. The mean boundary layer resistance to SO_2 transfer in our experiments was 100 s m^{-1}.

Each plant was allowed to acclimatise for one photoperiod in the chamber; on the second day, photosynthesis and transpiration in clean air were measured, and on the third day SO_2 was added at fixed concentrations ranging from 20 to 300 p.p.b. (1 p.p.b. = 10^{-3} p.p.m. $\hat{=}$ 2.86 μg SO_2 m^{-3}). To change stomatal resistance, irradiance was varied using neutral filters. Values of r_s ranged from 200 to 3,700 s m^{-1}. Throughout the experiments air temperature was 20°–21 °C and relative humidity was 50–60%.

Figure 2 shows the values of $(CF^{-1}-r_b)^{-1}$ plotted against $(r_s+r_i)^{-1}$ when r_i was assumed zero. Regression analysis shows that the points are well fitted ($r = 0.99$) by a straight line with slope 1.02 ± 0.01 and intercept 0.28 ± 0.02 mm s^{-1}. The reciprocal of the intercept, 3,600 s m^{-1} corresponds to the resultant of r_e and (r_c+r_{ic}) in parallel (Fig. 1 and equation (3)) and it is not possible to calculate the values of these resistances independently from these measurements. However, Spedding[1] found that r_e for surface deposition of SO_2 on filter paper ranged from 2 to 5×10^3 s m^{-1} and if r_e is similar for bean leaves we conclude that (r_c+r_{ic}) must have been of the same order of magnitude as r_e to give a resultant of 3,600 s m^{-1}.

Further analysis of our measurements with different values assumed for r_i reveals that the uncertainty in the estimate of r_i is about 20 s m^{-1}, an order of magnitude smaller than the minimum stomatal resistance we observed. At a typical value of $r_s = 300$ s m^{-1}, analysis of the resistance network in Fig. 1 for the resistances derived here suggests that about 90% of the total SO_2 flux to the leaves entered the stomata and 10% was deposited on the surface and/or diffused through the cuticle. Although this latter figure was small in our experiments, it would be necessary to find out how surface and cuticular resistances are influenced by natural 'weathering' and other environmental factors in the field before total deposition of SO_2 on vegetation could be estimated reliably.

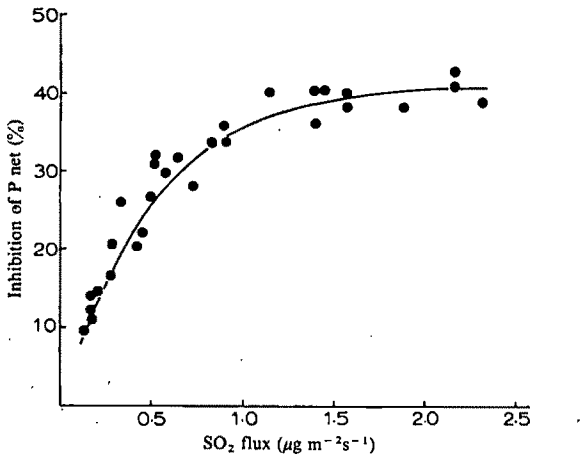

Fig. 3 Variation of the percentage inhibition of net photosynthesis in *V. faba* by SO_2, relative to clean air, with SO_2 flux entering through stomata. Plants were exposed to SO_2 concentrations ranging from 20 to 200 p.p.b. and the maximum depression in photosynthesis over 2 h was measured.

When plants of *Vicia faba* are exposed to SO_2, rates of net photosynthesis decrease relative to rates observed in clean air[10]. Figure 3 shows the percentage inhibition of net photosynthesis as a function of SO_2 flux density into stomata. In these measurements, plants were exposed for 2 h to SO_2 at concentrations ranging from 20 to 200 p.p.b., and the maximum decrease in net photosynthesis at light saturation was recorded. Fluxes of SO_2 into the stomata were calculated from equations (1) and (2) assuming $r_i = 0$.

By relating response(s) to pollutant flux rather than dose, the influence of different stomatal, surface and boundary layer resistances in different experimental systems is removed. Comparisons of response when fluxes are known may reveal better agreement between responses observed in different laboratories than is apparent from current literature. However, further work is necessary to determine whether specific responses depend on rates of uptake, on uptake integrated over long periods, or on more complex definitions of exposure.

Our measurements and analysis show that at the low and medium concentrations of SO_2 we used, the internal resistance to SO_2 uptake in *Vicia faba* was negligibly small. Consequently fluxes into plants could be estimated from the external SO_2 concentration and the appropriate stomatal resistance. If this result holds generally, the uptake of SO_2 by vegetation in the field or laboratory can be estimated either by relatively simple direct measurements of stomatal resistances and gas concentration or by reference to the extensive literature describing stomatal resistances of many natural and agricultural species. At the biochemical level, our finding that the internal resistance to SO_2 uptake was very small has significant implications for the mechanisms of action of SO_2 within plants.

'Helpers' in fox society

D. W. Macdonald

Department of Zoology, South Parks Road, Oxford, UK

Among the Carnivora the presence of non-breeding adults within social groups seems to be widespread, and evidence is accumulating that these individuals sometimes contribute to the survival of young born to other group members who may, or may not, be their relatives[1,2]. I describe here studies of both wild and captive red foxes, *Vulpes vulpes*, and report that non-breeding vixens occur in fox groups in some habitats. These barren vixens are subordinate to the breeding females, and may feed, guard, groom and play with the cubs of the breeding vixen within their group.

The social organisation of the red fox is still poorly understood, but it is certain that it varies between habitats and sometimes involves monogamous pairs and elsewhere small family groups, and that the proportion of barren vixens also varies between habitats[3,4]. Around Boars Hill, Oxford, fox groups comprise four or five adults, normally including one male

0028-0836/79/440069—03$01.00

© 1979 Macmillan Journals Ltd

and several related females, who share a group territory[5]. Of four groups studied in detail in 1973–74, 60% of the vixens were barren, that is, only one or two vixens had cubs in each group. Observations of encounters between barren and reproductive vixens within each group suggested that the breeding vixens were generally dominant amongst the adult vixens of their group. Radio-tracking and direct observation showed that some barren vixens visited breeding earths where they were frequently seen playing with cubs, and circumstantial evidence suggested that they also provided food for the cubs. Where two litters are born within one territory, they may be communally reared in the same earth.

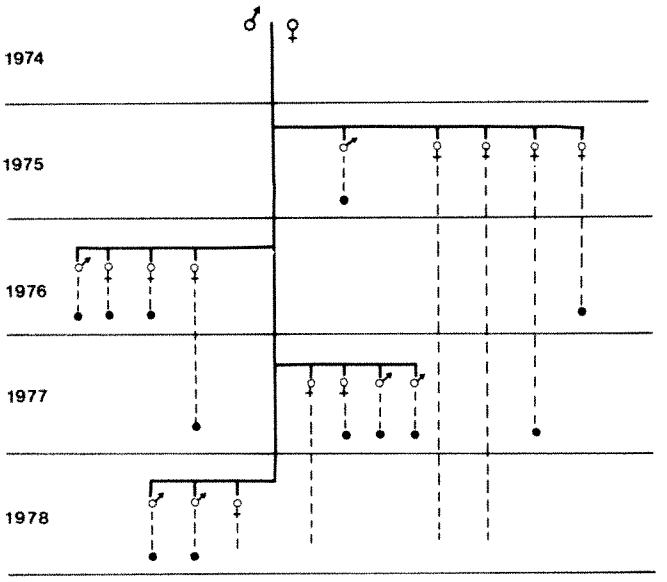

Fig. 1 The genealogy of a captive group of foxes (group I), showing that during 1974–78 only one vixen bred. ● Indicates that individuals were removed from the group. Some non-breeding females acted as helpers.

To study fox reproductive behaviour, two family groups, each mimicking the composition of wild groups, were watched in 1,000-m^2 enclosures. Group I grew from a pair and their offspring; group II grew from a male and three full sisters of the same age. Hence, both groups comprised related animals. During 1974–79, the groups' composition changed with the addition of cubs each year. All subadult males were removed each autumn, as were some vixens of randomly selected ages.

In eight cumulative years of study of the two groups, the maximum productivity would have been 27 litters. In fact, only seven litters were born (32% productivity, see Fig. 1). Every year except one, only one vixen gave birth to cubs in each group and in every year only one vixen's cubs survived in each group. The male ignored the other females during the mating period and their oestrous condition could not be determined externally. In group I the same vixen bred for 5 yr, throughout which she was consistently dominant to all the others. In group II only one vixen bred in 3 out of 4 yr and two bred in 1 yr, but the identity of the breeding individual changed from year to year. However, in every case the breeding vixen was dominant to the others during the winter in which she bred (see Fig. 2).

In each group some of the non-breeding vixens visited the newborn cubs frequently, but briefly, for the first 3 weeks of their lives; thereafter, they behaved in a way which might promote cub survival by providing food, security and grooming (Table 1). They also attacked wild foxes outside the enclosures while the mother was tending to her cubs, or heavily pregnant. As cubs grew, the litters were split so that some cubs rested with their mother while others rested with non-breeding females. Table 1 shows that each member of a captive family group often participated in tending to the cubs. However, the percentages given do not necessarily numerically reflect the benefit to the cub that accrued from the behaviour of a particular adult, nor the costs to the adult of its behaviour. This is because the adults did not all 'help' at the same time, nor did they have equal access to the resources they gave to the cubs.

In 1976, the breeding vixen of group 1 suffered a serious injury to a front paw when her cubs were 4 weeks old. On only 2 out of 16 days following the injury was the vixen able to tend to her cubs, but during this period they were found with non-breeding vixens, with whose care they all survived.

In the winter of 1977–78 in group II, the dominance of vixen WP over vixen BE waned, so that by January 1978 they were of equal status (assessed by frequency and direction of amicable and aggressive interactions). Perhaps as a consequence of their equal status, both vixens conceived. By the time the cubs were born, BE was clearly dominant to WP. In the previous year WP had been a successful mother while BE had been a diligent 'helper'. This year BE's cubs were born 13 days before those of WP. During those 13 days BE tended her own cubs. When WP's cubs were born she (WP) repeatedly picked them up and carried them around the enclosure, giving submissive shrieks and adopting submissive posture. Sometimes this 'panic' seemed spontaneous but on other occasions it was prompted by BE's approach. WP's cubs soon succumbed to this treatment. The death of the last cub at 8 days old was followed by a sudden change in WP's behaviour; dropping the corpse outside BE's artificial earth, WP entered and submitted to BE. During the next 10 min WP visited BE's cubs 10 times (having not done so since the birth of her own cubs), and BE visited WP's now empty earth three times. On return from the third trip BE found WP suckling her cubs; the two vixens greeted and BE wandered off leaving WP with her cubs. WP's agitated behaviour had disappeared completely. The two vixens reared BE's cubs cooperatively thereafter.

Table 1 Behaviour of each member of a family group of foxes towards a litter of cubs

	Father Sm	Mother WP	Aunt BE	Aunt WE
Provide food $n = 151$	41.1	21.2	17.9	19.9
Guard $n = 82$	2.4	25.6	61.0	11.0
Retrieve $n = 30$	13.3	43.3	40.0	3.3
Groom/play $n = 139$	34.5	12.9	32.4	20.1

Values given are the percentage of each of four categories of behaviour undertaken by each member of the group towards the litter (born 19 March) between 5 April, when the cubs began to eat meat, and 18 June 1977. The behaviour categories are providing food, guarding in the earth, retrieving cubs straying from the earth and grooming or playing with cubs.

Each year, in the first 3 weeks following the birth of her cubs, the dominant vixen, irrespective of her identity, furiously attacked the most subordinate of the other vixens, although amicably greeting the more dominant of the subordinates. Each year the more dominant of the subordinate vixens began to feed the cubs earlier than did the more subordinate females. As they began to feed the cubs, each helper suddenly gained 'confidence' during encounters with the male fox. The male frequently played with the cubs and never seemed to threaten their safety. He regularly fed the cubs and, from the moment of their birth, he both fed their mother and cached food around the natal earth.

The female helpers never fed the mother, only the cubs. In spite of their otherwise similar behaviour, foxes apparently differ from jackals[1] in two important respects; jackal helpers feed the breeding female, and male and female jackals are equally likely to act as helpers, whereas most (perhaps all) young male foxes leave the group in their first year[6,7].

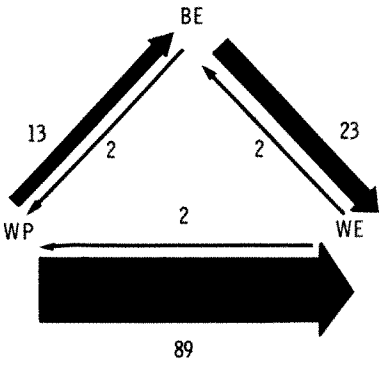

Fig. 2 The number and direction of aggressive interactions between three full sisters within a family group of foxes during the 1977 breeding season (proportion of interactions indicated by arrow thickness). Of 660 interactions recorded between group members, 131 involved aggression between these three females. On this basis a linear hierarchy of WP, BE, WE can be seen.

The mechanism underlying the male foxes' lack of sexual interest in non-breeding vixens is unknown. Two ideas could explain why in the wild the barren vixens remain in the group where they do not breed but do apparently contribute to the survival of another individual's offspring. The helpers may be 'hopeful reproductives'[8], maintaining a group structure and territory which confer benefits which may at some future time be theirs. The second possibility is that the helpers gain through direct increase in their inclusive fitness (kin selection)[9] by increasing the chances of survival of cubs to which they are related. These two hypotheses are not mutually exclusive and their relative importance depends, in practice, on the extent to which female membership of fox groups is restricted to relatives. The evidence so far suggests that immigration into established groups is not common and, because helpers could simultaneously be relatives and 'hopeful reproductives', there is no way of deciding whether one or both explanations is correct.

Post-mortem studies of fox reproduction in various habitats have shown differences in the proportion of barren vixens between areas and from one year to the next[3,10] and between 'age classes'[11]. These studies suggested that breeding is influenced by density-dependent factors. Reproductive suppression of subordinate vixens in those areas where ecological circumstances permit the formation of multi-female groups could be just such a factor.

I thank H. Kruuk, P. D. Moehlman and H. N. Southern for stimulating discussions.

A unique form of locomotion in a stomatopod—backward somersaulting

Roy L. Caldwell

Department of Zoology, University of California, Berkeley, California 94720

Of the diversity of forms of locomotion evolved by life on Earth, one that seems not to have developed to any great extent is rolling or somersaulting. Many cultures claim the existence of 'hoop snakes' that grasp their tails in their mouths and roll downhill, but no known snake can perform this feat[1]. Furthermore, although at least one spider (Hamilton, personal communication) when disturbed forms its body and legs into a sphere and rolls down sand dunes, I have been unable to find examples of animals that roll uphill or even over level terrain. Various coelenterates such as *Hydra* and some sea anemones somersault slowly across the substrate by alternating attachment of the pedal disk and tentacles. However, with the exception of human gymnasts and other playful primates, I report here a unique form of locomotion found in the stomatopod *Nannosquilla decemspinosa* (Rathbun, 1910) that consists of a rapid series of backward somersaults.

N. decemspinosa is a small stomatopod growing to a maximum body length of 23 mm. This predatory marine crustacean is found in sand substrates on the Pacific coast of Central and South America. The population studied occurred in the lower third of the intertidal zone on a sand beach on Naos Island, Canal Zone. Individuals excavate 10–15-cm vertical burrows stabilised by a mucus secretion mixed with the sand. When covered by water, the animals sit at the entrance with only their eyes and antennules protuding, waiting for passing prey. When their burrows are exposed at low tide, *N. decemspinosa* close the entrance with a few sand grains and retreat to the bottom of the burrow. *N. decemspinosa* rarely leave their burrows except to dart out and seize prey (usually less than one body length), to locate mates, and when strong wave action destroys their dwelling. When out of the burrow in water, they almost always swim using their five pairs of abdominal pleopods for propulsion. They seldom take more than a few steps on the substrate. One exception is during burrow construction, when they will carry sand 1 or 2 cm from the entrance. Inside the burrow, they use their laterally directed walking legs, as well as their pleopods, in moving quickly up and down. At low tide, if exposed by wave action, they swim if there is as little as a millimetre of water. However, if the sand is well drained and only moist, they are incapable of walking and use a radically different form of locomotion—backward somersaulting. The animal rolls over on its back and brings the telson up over its body, planting it immediately in front of the head, forming a nearly closed loop. Waves of flexion then pass anteriorly from the posterior abdomen and another from the posterior thorax, rolling the animal forward. Finally, the head and carapace are pulled up over the rest of the body and flip over the top so that the animal is once again lying stretched out on its back. At this point the telson is again flexed anteriorly and a new cycle begins (Fig. 1).

The animal continues a series of backward somersaults, generally moving in a straight line until it encounters an obstacle or water sufficiently deep for swimming, or until it becomes fatigued. Although the longest track recorded was just over 2 m, most animals travelled somewhat less than 1 m. The distance covered by each somersault is basically the length of the body. As the average adult is 20–23 mm long, the animals made 20–40 consecutive somersaults.

Body length and speed were positively correlated ($r = 0.857$, $n = 30$, $P < 0.001$) (Fig. 2). Thirty animals ranging in length from 12 to 23 mm were brought into the laboratory. Each was

0028-0836/79/440071—03$01.00

© 1979 Macmillan Journals Ltd

placed on a level, damp sand substrate and the total length and time taken for a somersaulting track recorded. The sand surface seemed identical to that of the beach at low tide. Animals were started by dropping them onto the sand from a height of 5 cm. All immediately began somersaulting. Curved tracks and those shorter than 15 cm were not scored and the animals were retested several minutes later. In this series of tests, speeds ranged from 1.5 to 4.5 cm s^{-1}. In other trials, the maximum speeds recorded were 5.6 cm s^{-1} for a 20-mm female and a 23-mm male.

To determine whether the animals take any particular orientation with respect to the beach when somersaulting, several individuals were dug out of their burrows at low tide (during both the day and the night) and were dropped immediately onto smooth sand near their burrow. The initial direction taken was then noted. Direction taken was not significantly different from random orientation, although there was a tendency for animals starting uphill to curve more often than those heading downhill. However, *N. decemspinosa* could somersault up slopes as steep as 10°, and in the laboratory on a wooden substrate some animals could climb even a 30° incline.

This unique form of locomotion in *N. decemspinosa* seems to have evolved in conjunction with other morphological adaptations related to inhabiting fine sandy substrates. The *Nannosquilla* body type is among the most slender, dorsoventrally flattened and loosely articulated of any stomatopod[2]. This allows it to use small-diameter burrows requiring a minimum of time, effort and stabilising mucus for construction. It is particularly important to *N. decemspinosa*, as this species frequents sandy beaches where burrows are commonly destroyed by wave action. *N. decemspinosa* also is capable of making jack-knife turns in a tube barely larger in diameter than its own width. When digging, it proceeds to the bottom of its burrow headfirst, grabs a load of sand in its maxillipeds, makes a U-turn and carries the sand to the surface. Thicker and more tightly articulated stomatopods, such as the cavity-living gonodactylids or squillids inhabiting U-shaped burrows, cannot turn 180° in such narrow quarters and would require a relatively larger diameter burrow.

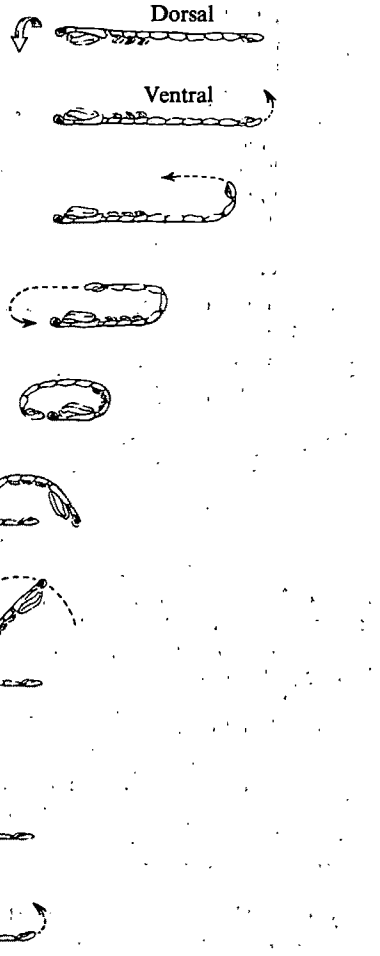

Fig. 1 One cycle in the backward somersaulting of the stomatopod, *N. decemspinosa*. If the animal is dorsal side up, it rolls over onto its back. It then draws the telson up over its head, rolls forward until the head and thorax are flipped up over the body, and lands with the body again stretched out on its back. Animals may complete 20–40 consecutive somersaults.

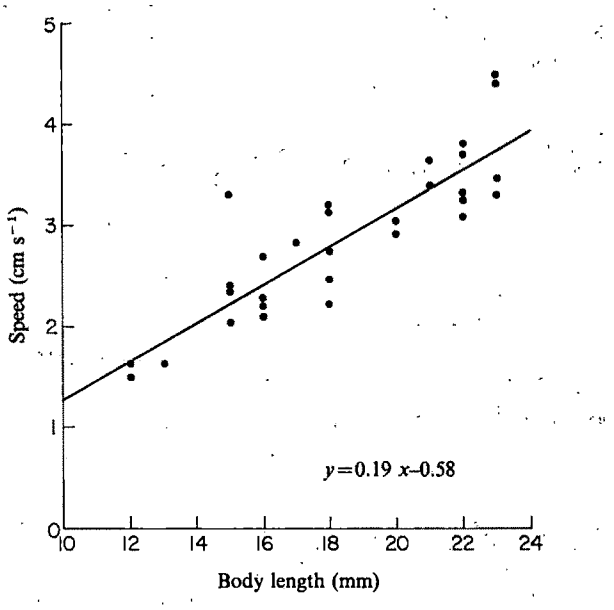

Fig. 2 Speed of backward somersaulting as a function of body length in *N. decemspinosa*. Each point represents a single individual somersaulting on smooth sand. Body length and speed were positively correlated ($r = 0.857$, $n = 30$, $P < 0.001$).

Most intertidal stomatopods, when exposed on dry land, are capable of crawling using their walking legs. A few can also inch their way forward using their spined telsons to push themselves along. The long, slender body of *N. decemspinosa* offers too much resistance in contact with the substratum for its legs to pull it forward, and the laterally directed legs are too short and weak to lift the body off the sand to reduce friction. The alternative method is somersaulting. Although the turning movements used in the burrow are different from those used while somersaulting (turns in the burrow are made headfirst while somersaults are telson-first), the flexibility essential for making U-turns in the burrow is also required for somersaulting. Also, the dorsoventral flattening provides a broad, flat dorsal surface that gives the animal considerable stability while rolling. Most stomatopods have more rounded dorsal surfaces in cross-section. Thus, although the evolution of the long, slender body makes it impossible for *N. decemspinosa* to move on dry surfaces by walking or crawling, it does provide the flexibility needed for somersaulting.

The data suggest that there is no initial orientation with respect to the slope of the beach during somersaulting. However, the animals are proceeding in an anterior direction and can see objects in their path. Several times, somersaulting animals stopped before running into objects, but there was no indication that they could alter their course to avoid obstacles. When animals were rolling along parallel to the beach, they frequently curved downhill towards the water. This was presumably due to gravity pulling them in that direction, much as a hoop rolled across a slope will curve downhill. Thus, although animals somersault in any direction, even uphill, and do not seem to orientate in any particular direction, there is a tendency to move down the beach towards water. As they are

most likely to be exposed by wave action when the tide is coming in or going out, movement of only 1 or 2 m down the beach would probably bring them back into contact with water.

I have observed one other species of *Nannosquilla* (not described from the Atlantic coast of Panama), and it also somersaulted when exposed. Similar morphology in other *Nannosquilla* species would suggest that they may also possess this ability. Interestingly, another species of stomatopod, *Acanthosquilla digueti*, that is found in micro-sympatry with *N. decemspinosa* and has a very similar body shape, does not somersault. When exposed, it turns over on its back as does *Nannosquilla* and flips its telson up over its head, but it does not continue the motion completing the somersault, and simply flops back and forth. I have never seen it make two consecutive somersaults. Whether other lysiosquillids with similar morphologies can locomote by somersaulting is unknown.

I thank Gloria Sullivan for comments on the manuscript and Phyllis Thompson for the illustrations. Support was provided by NSF grant no. BNS74-24004.

Protective immunisation of mice using cell surface glycoprotein from *Trypanosoma cruzi*

Martin T. Scott & David Snary

Departments of Experimental Immunobiology and Immunochemistry, The Wellcome Research Laboratories, Beckenham, Kent, UK

The parasitic protozoan *Trypanosoma cruzi* is the causative agent of the chronic debilitating Chagas' disease in man. It is estimated that at least 12 million people in South and Central America are infected with *T. cruzi*, for which there is so far no suitable chemotherapy[1,2]. The development of vaccines using killed or attenuated whole organisms is hindered by the presence of endotoxin-like material in the protozoa[3], and the possible existence of antigens in *T. cruzi* which cross-react with, and thereby stimulate immunity against, mammalian heart and nervous tissue[4,5]. Because autoimmunity induced in this way has been thought to cause the cardiac and neural lesions characteristic of the chronic stage of the disease[6,7], it has been assumed that immunisation based on a whole organism vaccine might carry the risk of itself inducing symptoms of the disease. Recently an integral membrane glycoprotein of molecular weight 90,000, was isolated from the cell surface of *T. cruzi*. It is the only major cell surface glycoprotein, it is present throughout the life cycle of the parasite[8], and it does not undergo antigenic variation[9]. We have successfully protected mice against acute lethal *T. cruzi* infection by vaccinating them with glycoprotein in combination with adjuvants. Moreover this glycoprotein does not seem to be the one carrying the antigens causing autoimmune antibody formation.

The prophylactic immunisation of mice with *T. cruzi* glycoprotein in conjunction with either Freund's complete adjuvant or saponin as adjuvant against a subsequent lethal challenge with Y strain *T. cruzi* is illustrated in Fig. 1. (The successful use of saponin as an adjuvant for immunising mice with various whole *T. cruzi* vaccines has been described previously[10].) Unimmunised C57BL/6 mice (Fig. 1*a*) all developed high blood parasitaemias and died (mean survival time, MST, 24.2 ± 0.75 days). Immunisation with Freund's complete adjuvant alone was not protective as judged by either blood parasitaemia or survival time (MST 25.2 ± 0.5 days). After immunisation with glycoprotein alone all mice died but parasitaemia was delayed and

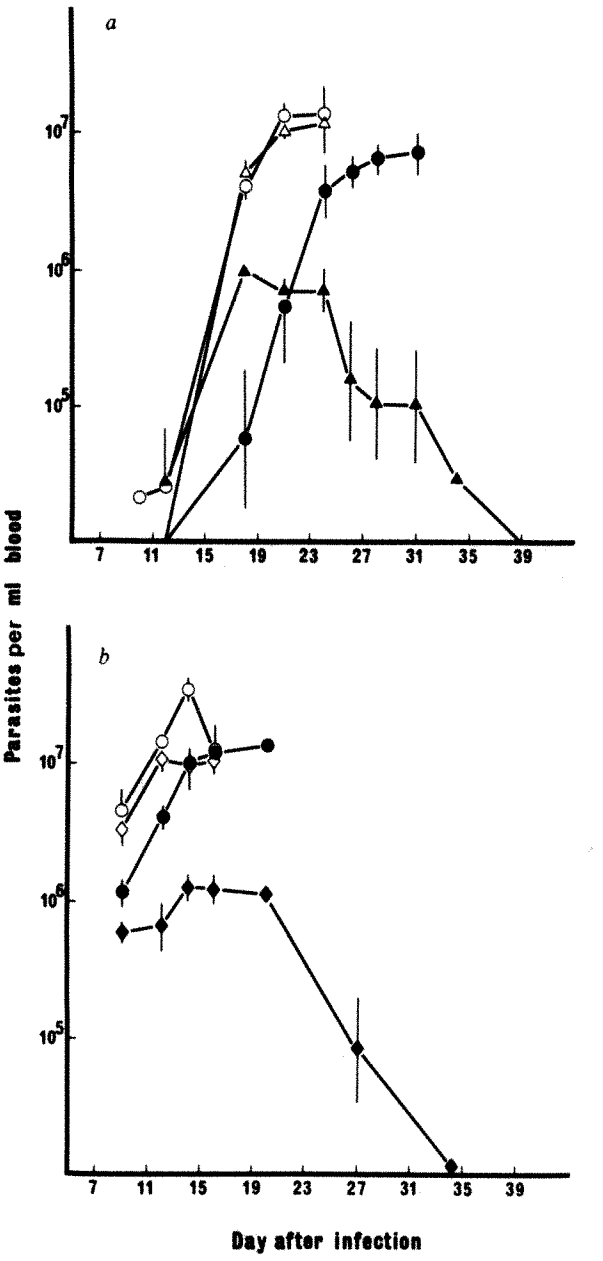

Fig. 1 Protection of mice against acute lethal *T. cruzi* infection by immunisation with *T. cruzi* glycoprotein and adjuvant. *a*, Female C57BL/6 mice were immunised s.c. with 100 μg glycoprotein emulsified in an equal volume of Freund's complete adjuvant (Difco) (▲), glycoprotein alone (●) Freund's complete adjuvant alone (△), or were untreated (○). Immunisation was repeated after 14 days and, 14 days after the second injection, all mice were challenged s.c. with 5×10^3 Y strain blood trypomastigotes from mouse passage. At the times shown, 10-μl blood samples were taken, mixed with 0.87% ammonium chloride, and parasites counted using a phase contrast microscope. There were five mice in each group and the vertical lines shown represent ± s.e.m. *b*, Female (CBA × C57BL/6)F_1 mice were immunised as in (*a*) except that 50 μg of *Quillaya* saponin (SPL Boake Roberts and Co.) was substituted for Freund's complete adjuvant. Mice were challenged s.c. with 7.5×10^4 Y strain trypomastigotes. ◆, 100 μg glycoprotein plus 50 μg saponin; ●, glycoprotein alone; ◇, saponin alone; ○, untreated control. There were five mice in each group and the vertical lines represent ± s.e.m. Glycoprotein: for the above experiments a clone of epimastigotes (Wel Tryp Y_2-C_1) was used as a source of glycoprotein. Culture conditions and glycoprotein preparation using the lectin from *Lens culinaris* for affinity chromatography were described previously[8] except that the non-ionic detergent Renex 30 (Honeywell Atlas) was used to solubilise the glycoprotein and throughout the fractionation procedure. Glycoprotein was precipitated by adding 3 vol. of ethanol and incubated at −20 °C for 48 h. The precipitated glycoprotein was resuspended in phosphate-buffered saline for immunisation.

‡ Absorbed with 45 mg lyophilised epimastigotes ($\simeq 4.5 \times 10^9$ organisms per ml serum; 1 h at 37 °C and then overnight at 4 °C.

§ Absorbed with glycoprotein (500 μg protein, $\simeq 10^{10}$ organisms per ml serum; 1 h at 37 °C and then overnight at 4 °C.

survival prolonged (MST 31.2 ± 1.2 days). The combination of glycoprotein with Freund's complete adjuvant significantly reduced parasitaemia levels and allowed all mice to eliminate parasites from the blood, as judged by microscope count, and survive. The same pattern was seen in (CBA × C57BL/6) F_1 mice where saponin was substituted for Freund's complete adjuvant (Fig. 1*b*): mice immunised with glycoprotein in conjunction with saponin all cleared their blood parasites and survived whereas those receiving either glycoprotein or saponin alone died with high blood parasitaemias. In the experiment shown the degree of protection afforded by immunisation with glycoprotein alone was less than seen in the previous experiment (Fig. 1*a*), however, in other experiments it has been more marked. It is clearly variable and, being relatively weak, its protective capacity probably depends on the virulence of the individual experimental challenges.

A characteristic manifestation of the autoimmunity associated with Chagas' disease is the development of autoantibody directed against endocardium, vascular and interstitial tissue in mammalian heart (EVI antibody[4]). To determine whether the glycoprotein antigens shared identity with the tissue antigens against which *T. cruzi*-induced autoimmunity is directed, serum from a human Chagas' disease patient showing characteristic EVI activity (Fig. 2) was absorbed with glycoprotein. Table 1 shows that whereas absorption of serum with lyophilised whole *T. cruzi* epimastigotes significantly reduced anti-EVI activity and completely abolished anti-*T. cruzi* activity, absorption with glycoprotein did not affect the anti-EVI titre and was less effective at reducing anti-*T. cruzi* activity. These data indicate that the glycoprotein and the relevant tissue antigens do not cross-react, and also confirm that the glycoprotein represents only a part of the antigenic profile of the whole organism. Five further sera from human Chagas' disease patients (mean EVI titre $\log_2 6.7 \pm 0.4$) have been similarly absorbed and again absorption with glycoprotein did not significantly reduce EVI activity (titre $\log_2 6.2 \pm 0.5$), whereas absorption with whole *T. cruzi* epimastigotes did (titre $\log_2 4.3 \pm 0.8$).

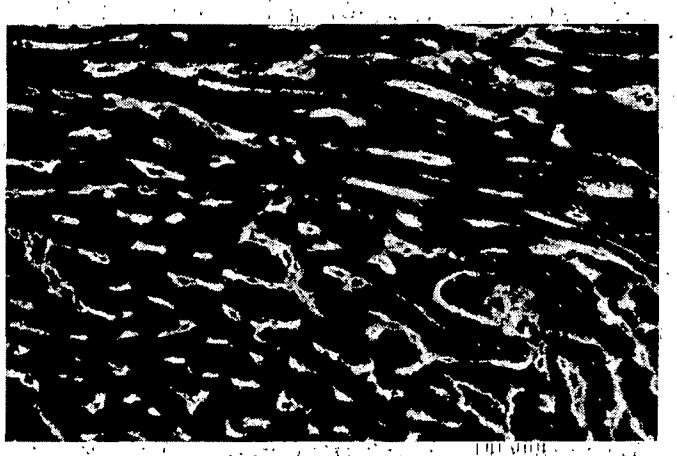

Fig. 2 Characteristic EVI reactivity of human Chagas' serum against mammalian heart tissue. Cryostat sections of mouse heart (5 μm thick) were prepared and stored at −20 °C. They were incubated with serial dilutions of test serum for 20 min at room temperature, washed, developed with a 1 in 20 dilution of FITC-labelled rabbit anti-human IgG (Miles Yeda) for 20 min at room temperature and, after a final wash, examined using a fluorescence microscope. Normal human serum in identical conditions gave no detectable staining.

These results together with the protection data suggest that the glycoprotein could be a candidate antigen for a vaccine against American trypanosomiasis. Immunisation with glycoprotein alone was partially protective as evidenced by slight, but significantly, lower blood parasitaemias and prolonged survival times. Further research should establish whether the adjuvant requirement is absolute for optimal immunisation with the glycoprotein and, if so, whether clinically acceptable adjuvants may be substituted. We also require to know whether any glycoprotein-based vaccine is capable of achieving sterile immunity, and being prophylactically effective against later development of chronic forms of Chagas' disease. It has been proposed that the late pathological manifestation of chronic Chagas' disease develops as a result of tissue damage inflicted during the acute phase of infection[11]. Any reduction in the acute phase may, therefore, in addition to reducing the mortality associated with acute infection, also decrease the incidence or severity of the chronic form of the disease.

We thank Dr L. Hudson, St. George's Medical School, London and Dr E. L. Segura, Instituto National de Diagnostico e Investigacion de la Enfermedad de Chagas, Buenos Aires, Argentina for providing sera from Chagas' disease patients. Thanks also to Mrs K. Brown, Mr M. A. Smith and Miss J. Walker for technical assistance.

Interferon enhances 2-5A synthetase in embryonal carcinoma cells

John N. Wood & Ara G. Hovanessian
Viral Oncology Unit, Institut Pasteur, Paris 15, France

Mouse teratocarcinomas provide a useful model of mammalian differentiation, because the malignant embryonal carcinoma (EC) stem cells of such tumours may produce various differential cell types *in vivo* or *in vitro*[1]. Many EC cell lines have now been established and classified on the basis of their ability to differentiate *in vivo* into cell types characteristically derived from any of the three germ layers[2,3]. There is convincing evidence that EC cells can neither produce interferon, nor respond to it by becoming resistant to virus, whereas differentiated cells derived from EC lines behave normally in both respects[4]. We investigated the lack of responsiveness of EC cells towards interferon by measuring the levels of two double-stranded RNA -dependent enzyme activities recently shown to be enhanced by interferon[5,6].

We report here that on treatment with interferon, EC cells show increased 2–5A synthetase levels comparable to those found in differentiated cells, while there is little or no effect on kinase activity in EC cells, in contrast to their differentiated counterparts.

The conditions of culture and sources of the cell lines used have been described elsewhere[7,8]. Briefly, all the EC cell lines used are derived from the transplantable ascitic form of the OTT 50-60 teratocarcinoma isolated by Stevens[9]. PCC3/A/1 and PCC4AzaR1 are multipotent lines which give rise to a variety of differential cell types *in vivo*, and in appropriate conditions *in vitro*[8]. The line 3/A/1-D-1 M is a cloned differentiated derivative of PCC3/A/1. These non-malignant cells characteristically give rise to bone *in vivo*. As well as this line, mouse L929 cells were used as differentiated controls which respond to interferon by the establishment of antiviral state.

The first 2-5A synthetase, forms oligonucleotides of the series pppA(2'p5'A)n—collectively referred to as 2-5A—which potently inhibit protein synthesis *in vitro* and *in vivo*, probably by activation of a nuclease[10–14]. The kinase studied, phosphorylates a protein of molecular weight 67,000, a 38,000-MW protein which is almost certainly the small subunit of initiation factor eIF2, and exogenous histones[5,15–18].

The 2-5A synthetase and the protein kinase were assayed after partial purification on columns of poly(I) . poly(C)–Sepharose as elsewhere described[5,6]. The column-bound synthetase is stable, thus providing a convenient method for the synthesis of 2-5A free of the enzyme responsible for its degradation[5]. Similarly, the poly (I) . poly(C)–Sepharose-bound protein kinase is stable and free of any phosphatase activity which may be present in the cell extracts[5].

Figure 1 shows a typical comparison of the kinase activity in PCC3/A/1 cells and their differentiated derivatives 3/A/1-D-1 M, together with L929 cells with and without interferon treatment. The enhanced phosphorylation of the 67,000-MW polypeptide is apparent in cell fractions from L929 and 3/A/I–D–1 M cells (Fig. 1, lanes 2, 6) but not from PCC3/A/1 cells (Fig. 1, lane 4). As a test for enhanced kinase activity, phosphorylation of calf thymus histones was analysed by the poly(I) . poly(C)–Sepharose-bound enzyme fractions. As expected of interferon-treated cell extracts, there was an enhanced phosphorylation of one of the major histone bands in fractions from L929 and 3/A/1-D-1 M cells (Fig. 1, lanes 8, 12) but not from PCC3/A/1 cells (Fig. 1, lane 10). Phosphorylation of the 67,000-MW protein and added histone by the poly(I). poly(C)–Sepharose-bound enzyme(s) fractions (Fig. 1) from extracts of cells untreated with interferon was also apparent although to a lesser extent, as previously observed[5,6]. To quantitate the increase in kinase activity on interferon treatment, histone bands were cut out of the dried gel (using the autoradiograms as a guide) and counted in a liquid scintillation counter. There was no apparent increase in the phosphorylation of histones by enzyme fractions from two EC cell lines (PCC3/A/1 and PCC4 AzaR1) after interferon treatment, whereas L929 and 3/A/1-D-1 M extracts showed, respectively, 2.6- and 2.8-fold increases (Table 1).

In contrast to these differences in kinase induction, both undifferentiated and differentiated cells showed similarly enhanced levels of 2-5A synthetase after interferon treatment (Table 1). The level of 2-5A synthetase in different extracts was quantitated by the capacity of the poly(I) . poly(C)–Sepharose-bound enzyme fraction to synthesise 2-5A on incubation with ATP. The heat-stable (95 °C for 10 min) inhibitor of cell-free protein synthesis generated on incubation of enzyme fractions from teratocarcinoma cells showed the same spectrum of resistance and sensitivity to alkali, micrococcal nuclease, snake venom phosphodiesterase and bacterial alkaline phosphatase as the corresponding material synthesised with extracts from L929 cells or rabbit reticulocytes (data not shown, similar to those in ref. 21), thus confirming that the inhibitor synthesised was the 2'5'-linked oligoadenylic acid triphosphate.

Treatment of cells with interferon induces both antiviral and anticellular effects[24,25]. These were assayed by the resistance to vesicular stomatitus virus (VSV) infection, and by inhibition of cell multiplication. As interferon does not induce an antiviral state in EC cells[4], it was of interest to attempt to correlate the induction of 2-5A synthetase in these cells with the anticellular

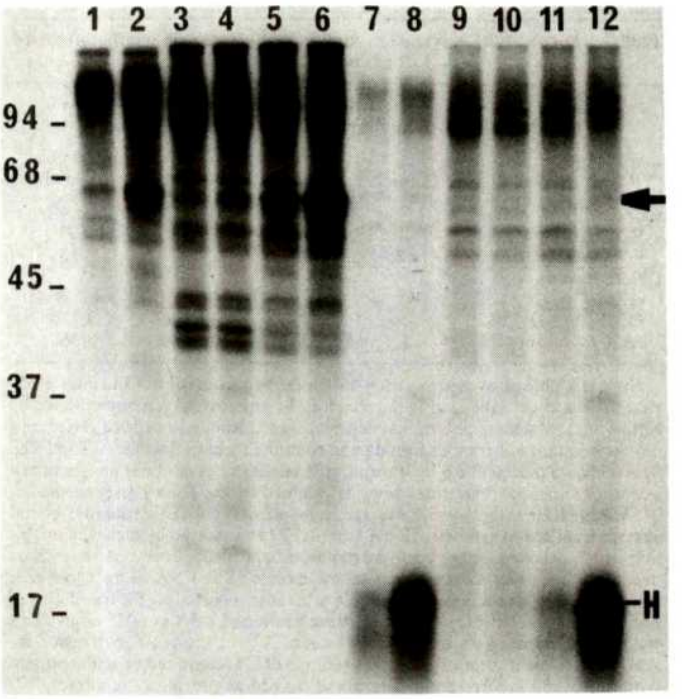

Fig. 1 Protein kinase activity of partially purified enzyme(s) fractions from control and interferon-treated cells: electrophoretic analysis on polyacrylamide (10%) slab gels containing SDS[19,20]. An autoradiograph of a stained, dried gel is shown. Chromatography on columns of poly((I) . Poly(C)–Sepharose, preparation of cell extracts and assay of the 67,000-MW polypeptide and histone kinase activities were as described previously[5,10,21]. PCC3/A/1, PCC4 AzaR1 and PCC3/A/1-D-1 M cells were grown in Dulbecco modified Eagle's medium containing 15% fetal calf serum (Flow) in a 10% CO_2 humidified atmosphere at 37 °C. L929 cells were grown in basic medium (Eagle) with Earle's salts and 10% calf serum in otherwise similar conditions. Cell extracts (5,000*g* supernatant) were from control (lanes 1, 3, 5, 7, 9, 11) and interferon-treated (250 units ml^{-1}, 17 h) (lanes 2, 4, 6, 8, 10, 12) mouse cells. Cell lines: L929, 1, 2, 7, 8; PCC3/A/1, lanes 3, 4, 9, 10; PCCS/A/1–D–1M, lanes 5, 6, 11, 12; 67,000-MW polypeptide kinase, lanes 1–6. Poly(I) . poly(C)–Sepharose-bound enzyme(s) fractions from control and interferon-treated cells were incubated for 60 min at 30 °C with 0.15 mM[γ-^{32}P]ATP (7.1 Ci $mmol^{-1}$, Radiochemical Centre) in buffer containing glycerol (10.mM HEPES, 90 mM KCl, 10 mM magnesium acetate, 7 mM 2-mercaptoethanol and 20% glycerol, v/v). Phosphorylation of histone, lanes 7–12: poly(I) . poly(C)–Sepharose-bound enzyme fractions from control and interferon-treated cells were incubated (60 min, 30 °C) with 1 mM ATP. Calf thymus histone (Type IIA, Sigma, 1 mg ml^{-1}) and [γ-^{32}P]ATP (0.15 mM as above) were added and incubation continued for 60 min. All the samples (1–12) were heated (95 °C, 10 min) in electrophoresis sample buffer containing SDS and supernatants equivalent to 0.3 mg of cell extract applied to the gel. The position of the 67,000 MW polypeptide (arrow) and histone (H) are indicated to the right of the gel. The numbers to the left give the MWs of protein markers in thousands: phosphorylase B, 94; bovine plasma albumin, 68; ovalbumin, 45; chymotrypsinogen, 37; myoglobin, 17.5. The interferon used was an electrophoretically homogenous preparation of specific activity 2×10^9 units per mg, and was prepared and provided by E. De Mayer.

effects of interferon. As expected, no resistance to VSV was induced in EC cells by interferon, whereas L929 and 3/A/1-D-1 M cells showed complete resistance to viral infection (Table 2). Similarly the interferon-mediated inhibition of cell growth in L929 and 3/A/1-D-1 M cells (58% and 42%) was not observed in EC cells, even at high concentrations of interferon (Table 2). Interferon therefore induces the 2-5A synthetase in EC cells without consequent antiviral or anticellular effects. Previous observations on the response of embryonic tissue to interferon have demonstrated a lack of cell growth inhibitory activity[26] and a low antiviral response which, however, increases with age[27].

Table 1 Levels of 2-5A synthetase and protein kinase(s) in interferon-treated and control cells

Cell type	2-5A synthetase (pmol $mg^{-1}h^{-1}$)		Histone kinase (cpm $mg^{-1}h^{-1}$)	
	Control	Interferon-treated	Control	Interferon-treated
EC cells				
PCC3/A/1	<2	225	664	697
PCC4AzaR1	<2	575	987	953
Differentiated cells				
PCC3/A/1-D-1 M	2	418	1,346	3,774
L929	8	562	1,280	3,360

Histone kinase assays were carried out on extracts from control and interferon-treated cells as described in Fig. 1 legend. Relative activities were quantitated by cutting out the bands of phosphorylated exogenous histones from dried gels using a developed autoradiogram as a guide and counting them in liquid scintillant. The figures shown represent c.p.m. incorporated into histones per hour per mg of cell extract. Protein concentrations were determined by the Folin Lowry method[22]. 2-5A synthetase activity was measured using poly(I) . poly(C)–Sepharose-bound enzyme fractions to synthesise 2-5A from ATP[6] and assayed by means of inhibition of ^{14}C-labelled amino acid incorporation in a mouse L cell-free system as described[5,6]. Translation of turnip yellow mosaic virus RNA in an L cell-free system was carried out in similar conditions to those reported for the translation of encephalomyocarditis RNA[20,23]. The concentration of 2-5A in AMP equivalents was calculated from absorbance on the basis of A_{260} of 15.6×10^3 mol^{-1} cm^{-1} for AMP. The concentration of a standard solution of 2-5A required to inhibit protein synthesis by 50% corresponded to about 0.5 nM as previously reported[6,10,21]. 2-5A synthetase activities were calculated on this basis and are given as units corresponding to 1 pmol of 2-5A synthesised per hour per mg of cell extract.

Our present results agree with these observations and clearly show that there is no correlation between the induction of 2-5A synthetase and the establishment of an antiviral state, or anticellular effects in undifferentiated EC cells. However, one cannot exclude the possibility that the induction of the 2-5A synthetase, although not conferring an antiviral state in EC cells, might nevertheless have such a role in normal tissue, in conjunction with other factors such as enhanced kinase activity. Moreover, although the 2-5A synthetase activities in EC cells and differentiated cells may be the same, the absence of the 2-5A activated nuclease would presumably counter the *in vivo* effects of enhanced synthetase activity. We therefore measured the rate of degradation of VSV mRNA into acid-insoluble material by cell extracts incubated in the presence and absence of 2-5A (data not shown, similar to Fig. 6 in ref. 28). Enhanced nuclease activity was present in all cell extracts when 2-5A was added, suggesting that the 2-5A-dependent nuclease is present in both EC and differentiated cells. Nevertheless, it is still possible that the synthesis of 2-5A or its action could be inhibited in EC cells. In addition, the levels of synthetase activity measured here probably do not accurately reflect the *in vivo* activity of the enzyme, but rather its physical presence in, perhaps, a dormant form[29]. It should also be emphasised that as yet there is no direct evidence for any role of the 2-5A synthetase and protein kinase in the establishment of the antiviral response. The induction of these enzymes by interferon, therefore, may or may not be essential for the inhibitory process in virus replication in the interferon-treated and virus-infected cell. Whatever the situation, a function of 2-5A synthetase in interferon-treated EC cells remains to be established.

Table 2 Antiviral and anticellular effects of interferon

Cell type	Antiviral effects (log_{10} pfu ml^{-1})		Anticellular effects (cell number $\times 10^5$)		
				Interferon-treated	
EC cells	Control	Interferon-treated	Control	250 U ml^{-1}	3,000 U ml^{-1}
PCC3/A/1	2.1	2.3	21.2	23.3	21.0
PCC4AzaR1	3.0	3.0	61.4	65.0	70.0
Differentiated cells					
PCC3/A/1-D-1 M	2.4	>5.0	50.4	31.0	29.4
L929	2.4	>5.0	13.9	11.8	5.8

The antiviral state of control and interferon-treated cultures was compared by challenging cells with serial twofold dilutions of VSV and determining the concentration of the virus which could kill 50% of the challenged cells after 36 h. Tests were carried out in quadruplicate, using Nunclon 96-well microplaques containing about 30,000 cells per well. The figures represent the plaque-forming units (PFU) per ml of VSV causing 50% cytotoxicity on microscopic examination. These tests were carried out on the same cell batches used for synthetase and kinase assays (Table 1). Anticellular effects were measured on cells incubated with 250 or 3,000 U ml^{-1} interferon. Cells were plated out at a density of $1–2 \times 10^5$ cells per well in Linbro (6×4) 16-mm tissue culture dishes in the presence or absence of interferon. Cell numbers were counted daily for 3 d in quadruplicate treated and control cultures. The figures shown represent cell numbers per well at day 3, when the anticellular effects of interferon were most pronounced.

As interferon interacts with EC cells without causing any antiviral or anticellular effects, a comparison between EC cells and their differentiated counterparts may allow the distinction between those interferon-induced events essential for antiviral activity, and other consequences of interferon treatment. A correlation between antiviral and anticellular effects and enhanced kinase activity is confirmed in the present study. This interferon inducibility of the kinase may, in addition, provide a useful marker for distinguishing EC cells from differentiated cells in developmental studies using teratocarcinoma[30].

Prostaglandin D_2 controls pulmonary metastasis of malignant melanoma cells

Dale A. Stringfellow & Francis A. Fitzpatrick

Departments of Experimental Biology and Drug Metabolism, The Upjohn Company, Kalamazoo, Michigan 49001

Selective metastasis of malignant cells in various neoplastic processes is poorly understood. Metastasis seems to be associated with inherent biochemical and biological properties of tumour cells which guarantee their survival and multiplication. These properties may include surface enzymes[1], interaction with various host defence systems and cells[2–4], combination with host

0028-0836/79/440076—03$01.00

© 1979 Macmillan Journals Ltd

platelets[5], or with the host endothelial cells, and adhesiveness of the metastatic cell. Fidler[2,6,7] has developed a series of malignant melanoma cells that are useful for studying tumour metastasis. By comparing the moderate metastatic parent line, $B16F_1$, to the highly metastatic line, $B16F_{10}$, it is possible to study metastasis selectively. Prostaglandins influence various cell functions, and may be involved in regulation of neoplastic processes[8-10]. We have recently reported that prostaglandin D_2 (PGD_2) formation by malignant melanoma cells *in vitro* is inversely correlated with their metastatic potential[11]. The studies we describe here were designed to determine whether treating the cells with a cyclooxygenase inhibitor, which would block conversion of arachidonic acid to prostaglandins, would affect the metastatic rate of either cell. The results suggest that PGD_2 is involved in the metastasis of these cells.

Monolayers of $B16F_1$ and $B16F_{10}$ cells which had reached confluency (in 75-cm^2 plastic tissue culture flasks, grown in Eagle's minimum essential medium supplemented with 10% fetal calf serum) were incubated for 2 h with 20 $\mu g\ ml^{-1}$ of indomethacin, an irreversible fatty acid cyclooxygenase inhibitor[12]. Growth medium containing indomethacin was removed from the monolayers. Cells were then rinsed twice with phosphate buffer saline and then 10 ml per flask of Hank's balance salt solution without magnesium or calcium supplemented with 2% fetal calf serum was added to each flask. Cells were removed with rubber policemen and pipetted gently to achieve a single cell suspension. Cells were counted, suspended at 2.5×10^5 viable cells per ml and were distributed into plastic tubes, 2 ml per tube. Within 15–20 min of collection, cells were injected intravenously into C57BL/6J mice (Jackson Laboratories). Each mouse received 0.1 ml of cell suspension. Mice were housed in stainless steel cages and were killed 3 weeks later. Lungs were removed, fixed in 3.7% formalin solution, and the number of metastatic foci on each lung was determined using an American Optical stereo zoom microscope.

Injection of $B16F_1$ and $B16F_{10}$ malignant melanoma cells into their syngeneic host confirmed that the cells retained their differential metastatic phenotype. $B16F_{10}$ cells formed 5.1 ± 0.78 metastatic nodules per animal compared to $B16F_1$ cells which formed 1.7 ± 0.34 metastatic nodules per animal (Table 1). After treatment of the cells with indomethacin, *in vitro*, both $B16F_1$ and $B16F_{10}$ metastasis increased noticeably and there was a normalisation of metastatic differences between the two cells: $B16F_{10} = 8.9 \pm 2.8$ and $B16F_1 = 9.9 \pm 4.1$ (Table 1).

To extend these observations, the previous experiment was repeated. In this case, after cells were collected and suspended at 2.5×10^5 cells per ml in Hank's balance salt solution without magnesium or calcium, one tube received PGD_2 at a concentration that would give 2 $mg\ kg^{-1}$ PGD_2 when 0.1 ml was injected intravenously. Cells again were immediately injected into mice intravenously and 3 weeks later the number of metastatic foci per lung was determined. Results are presented in Table 2. These results confirmed again that indomethacin treatment increased the metastatic rate of the cells, particularly the less metastatic $B16F_1$ line. PGD_2 injection reversed, and decreased indomethacin-enhanced metastasis threefold. In these conditions, indomethacin-treated F_1 cells were slightly more metastatic than untreated F_{10} cells and PGD_2 injected simultaneously with both cells reduced the rate of metastasis. In these studies, the conditions were adjusted to achieve minimum levels of control metastasis so that an increase due to indomethacin treatment and any subsequent reversal by PGD_2 treatment would be more apparent. Although not shown, injection of prostaglandin $F_{2\alpha}$ and E_2 at 2 $mg\ kg^{-1}$ did not significantly affect the metastatic rate of either cell.

Prostaglandin D_2 is the principal arachidonic acid metabolite produced by $B16F_1$ and $B16F_{10}$ malignant melanoma cells[11]. We have previously demonstrated that a quantitative difference exists between the ability of $B16F_1$ and $B16F_{10}$ cells to metabolise arachidonic acid to PGD_2 and that this *in vitro* difference correlated inversely with their metastatic rate *in vivo*. Results presented here extend these observations and indicate that *in vitro* treatment of these cells with a compound that blocked conversion of arachidonic acid to prostaglandin increased the metastatic rate of the cells *in vivo*. This was particularly true for

the $B16F_1$ cells that were less metastatic but produced the most PGD_2. Indomethacin treated cells were also co-injected with PGD_2. If PGD_2 was controlling the metastatic rate of the malignant melanoma cells, exogenous reconstitution of their PGD_2 levels should reverse the effect of indomethacin. This was found to be the case. Cells that were made more metastatic by indomethacin treatment reverted to a less metastatic form on co-administration with PGD_2.

One mechanism proposed for B16 cellular metastasis is that platelets adhere to the surface of malignant cells, causing emboli which then plug or attach to the endothelial surface in capillary beds[5].

Prostaglandin D_2 in sufficient amounts inhibits platelet aggregation in several species[13,14], and we have verified this effect in C57B1/6J mice. Our results suggest that PGD_2 is directly involved in prevention of pulmonary metastasis, possibly through its influence on the formation of platelet–tumour emboli. Other effects of PGD_2 on cell–cell interactions, cellular membranes and host defence systems may also be involved.

Indomethacin neutralised the ability of these cells to make PGD_2 and increased their metastatic rate. Exogenous restoration of PGD_2 reversed the effect of indomethacin. The consolidated data from *in vitro* experiments[11] and these *in vivo* experiments are consistent with a role of PGD_2 in the inhibition of platelet–tumour emboli. These results suggest that PGD_2 is involved directly in control of metastasis of these malignant melanoma cells. It is not presumed, however, that this is the only mechanism controlling the metastatic rate of these cells. Other biochemical and biological properties of the cells may be intimately involved in the metastatic rate. Results do suggest, however, that PGD_2 is one natural, cellular component controlling pulmonary metastasis of malignant melanoma cells.

Naloxone-reversible effect of opioids on pinocytosis in *Amoeba proteus*

Jan-Owe Josefsson & Paul Johansson

Department of Pharmacology,
University of Lund, S-223 62 Lund, Sweden

A characteristic feature of induced pinocytosis in *Amoeba proteus* is the formation of broad channels by invagination of the cell membrane. This process, which requires Ca^{2+}, occurs in response to depolarising cations[1–4]. High Ca^{2+} levels reduce pinocytosis induced by cations such as Na^+ and $Tris^+$, whereas pinocytosis induced by K^+ is less affected by Ca^{2+} (ref. 4). Agents which interfere with the calcium metabolism of the amoeba will therefore either stimulate or inhibit pinocytosis induced by Na^+ (ref. 5). Among the agents which are supposed to reduce Ca^{2+} influx across cell membranes or otherwise decrease cellular availability of Ca^{2+} are the opiates and opioid peptides[6–9], high doses of which have been reported to affect the amoeba[10]. Accordingly, Met-enkephalin, morphine and codeine potentiate the inhibition of pinocytosis caused by Ca^{2+}-binding agents and reverse the calcium blockade of pinocytosis mediated by caffeine[11]. In this report we show that pinocytosis induced by Na^+ or $Tris^+$ is suppressed by β-endorphin, Met-enkephalin and morphine. These effects were abolished or diminished by an opiate receptor antagonist, (−)naloxone, by increasing the Na^+ concentration, or by addition of Ca^{2+}.

We used *Tetrahymena*-fed *Amoeba proteus* which were cultured in a modified Pringsheim medium[12] or in Prescott–James solution[13]. The results were similar irrespective of culture medium. Pinocytosis was induced by removal of the medium and addition of the inducing solution (100 mM NaCl at *p*H 6.0, 90 mM NaCl plus 10 mM Tris-HCl at *p*H 7.0, 100 mM Tris-HCl at *p*H 7.0 or culture media containing 0.1 mg ml^{-1} cytochrome *c*, Trasylol or lysozyme). Pinocytosis activity was determined by counting the number of pinocytotic channels using phase-contrast microscopy. Each amoeba was inspected for 30 s and the channels in 40 amoebae were counted during the first 20 min of the pinocytosis cycle. The mean number of channels per amoeba was taken as an index of pinocytosis activity. Further details of the methods for culture of cells and assay of pinocytosis activity are described elsewhere[3,14].

Morphine (4–40 nM), Met-enkephalin (0.2–2 nM) or β-endorphin (0.1–20 nM) (which we will describe collectively as opioids, to include both opiates and opioid peptides) decreased Na^+-induced pinocytosis by up to 75%. Only low doses of the three opioids were effective and so the relationship between the inhibitory effect of opioids and pinocytosis gave rise to U-shaped dose–response curves. Also, pinocytosis induced by cytochrome *c*, Trasylol or lysozyme was inhibited by the opioids (Table 1). These cationic proteins give rise to pinocytosis which resembles that induced by Na^+ with respect to Ca^{2+} requirements[3,4]. Pinocytosis induced by KCl, on the other hand, was not significantly influenced by the opioids. Low concentrations of (−)naloxone reversed the effects of the opioids whereas the same concentrations of (+)naloxone were not antagonistic. (+)Naloxone possessed about 1/10,000th the activity of (−)naloxone (Fig. 1). A similar low potency of (+)naloxone in three mammalian assay systems has been reported[15].

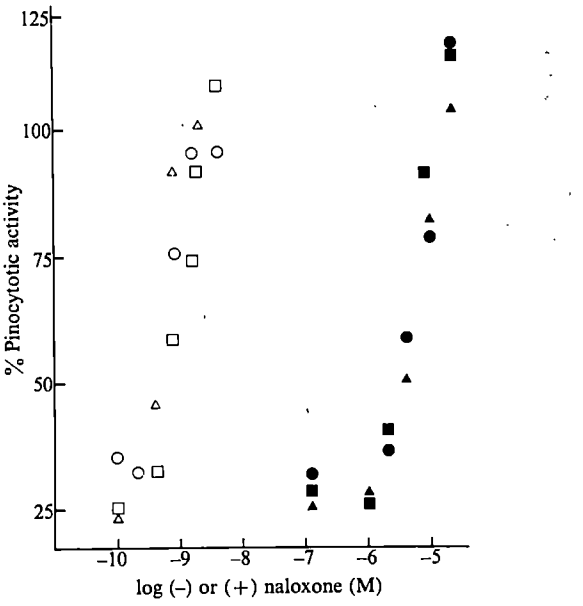

Fig. 1 Reversal by (−)naloxone (open symbols) and (+)naloxone (filled symbols) of the inhibition of pinocytosis due to 8 nM morphine (circles), 0.3 nM β-endorphin (squares) and 0.3 nM Met-enkephalin (triangles). Pinocytosis was induced by 100 mM NaCl, *p*H 6.0. The pinocytotic activities are given as per cent of the controls. The drugs were added to the inducing salt solution and the experiments were carried out at 23°C. Each experimental point represents a mean value of pinocytosis activity obtained from 40 amoebae during the first 20 min after induction. Note that the first part of the ordinate is deleted.

Table 1 Effect of opioids and naloxone on pinocytosis induced by NaCl (*a*) and cationic proteins (*b*)

a	NaCl 100 mM, *p*H 6.0	Plus 2 nM (−)naloxone	Plus 2 nM (+)naloxone	Plus 20 μM (+)naloxone
Control	100*	95±1.5 (7)	100±4.0 (7)	99±2.2 (7)
Morphine 8 nM	34±2.8 (7)	97±3.2 (7)	35±3.7 (7)	77±10.2 (7)
β-Endorphin 0.3 nM	39±5.1 (7)	90±3.9 (7)	33±3.8 (7)	75±10.4 (7)
Met-enkephalin 0.3 nM	28±2.2 (7)	95±6.6 (7)	25±2.0 (7)	

b	Cytochrome *c* 0.1 mg ml^{-1}	Plus 2 nM (−)naloxone	Lysozyme 0.08 mg ml^{-1}	Plus 2 nM (−)naloxone	Trasylol 0.1 mg ml^{-1}	Plus 2 nM (−)naloxone
Control	100*	101±2.9 (3)	100*	97±8.1 (3)	100*	102±3.8 (3)
Morphine 8 nM	55±4.5 (5)	109±5.8 (5)	44±3.6 (5)	93±3.2 (5)	56±6.3 (5)	107±11.3 (5)
β-Endorphin 0.3 nM	52±6.1 (4)	98±2.4 (4)	49±4.4 (4)	95±6.0 (4)	53±4.4 (5)	97±1.5 (5)

(+)Naloxone was synthesised[15] by A. E. Jacobson. Cytochrome *c* (type VI, Sigma) and Trasylol (Bayer) were dissolved in Prescott–James solution, and lysozyme HCl (Miles-Seravac) was added to the ordinary culture medium—Pringsheim solution.
* Pinocytosis intensity of controls are rated as 100%. Values are ±s.e.m. of the number of experiments given in parentheses.

The sensitivity of the amoeba to the opioids increased when Na^+ was replaced by the protonated form of Tris ($Tris^+$). This is shown in Fig. 2*a*, where substitution of $Tris^+$ for Na^+ increased the sensitivity to morphine about 10-fold. (−)Naloxone (0.6–2 nM) antagonised the effect of morphine on both Na^+- and $Tris^+$-induced pinocytosis (Fig. 2*b*). The results of this and similar experiments suggest that the potency of the antagonist against morphine or Met-enkephalin (Fig. 2*d*) is increased in the presence of Na^+. Compared with morphine, Met-enkephalin and β-endorphin were less influenced by Na^+ (Figs 2*c*, 3*c*).

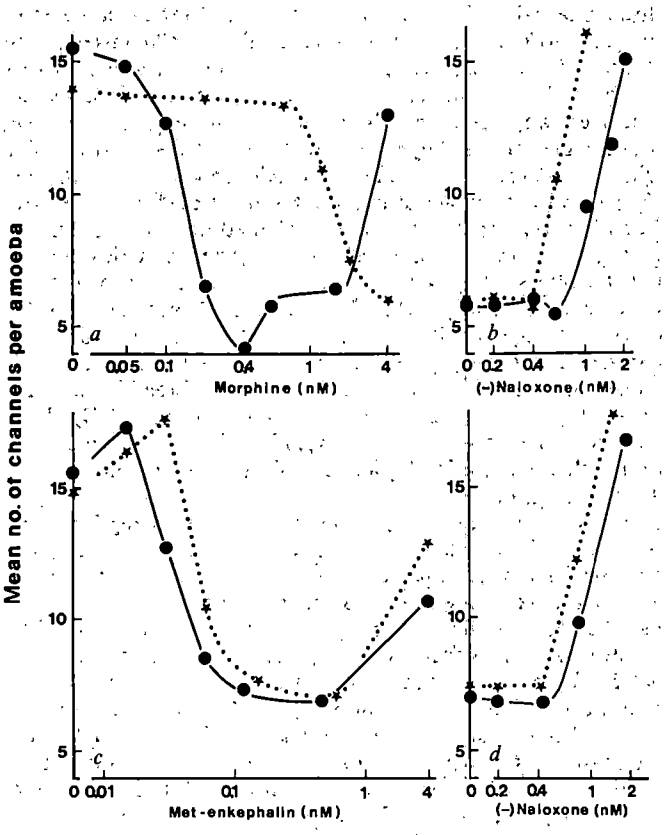

Fig. 2 The effect of morphine and Met-enkephalin on pinocytosis and its reversal by (−)naloxone. Pinocytosis was induced by 100 mM Tris-HCl (●) or 90 mM NaCl plus 10 mM Tris-HCl at *p*H 7.0 (Na^+-induced pinocytosis, ★). The conditions for the experiments were as described in Fig. 1 legend. *a*, The inhibitory effect of morphine chloride (ACO, Solna) on pinocytosis-induced by $Tris^+$(●) or Na^+(★). *b*, (−)Naloxone-HCl reverses the effect of 0.6 nM (●) and 4 nM (★) morphine on pinocytosis induced by Tris and sodium, respectively. The cells were from the cell culture used in the experiments of (*a*). *c*, The effect of Met-enkephalin on pinocytosis induced by $Tris^+$ (●) or Na^+ (★). *d*, Inhibition of pinocytosis by 0.12 nM (●) and 0.15 nM (★) Met-enkephalin (Beckman) is reversed by (−)naloxone. The same cell culture as (*c*).

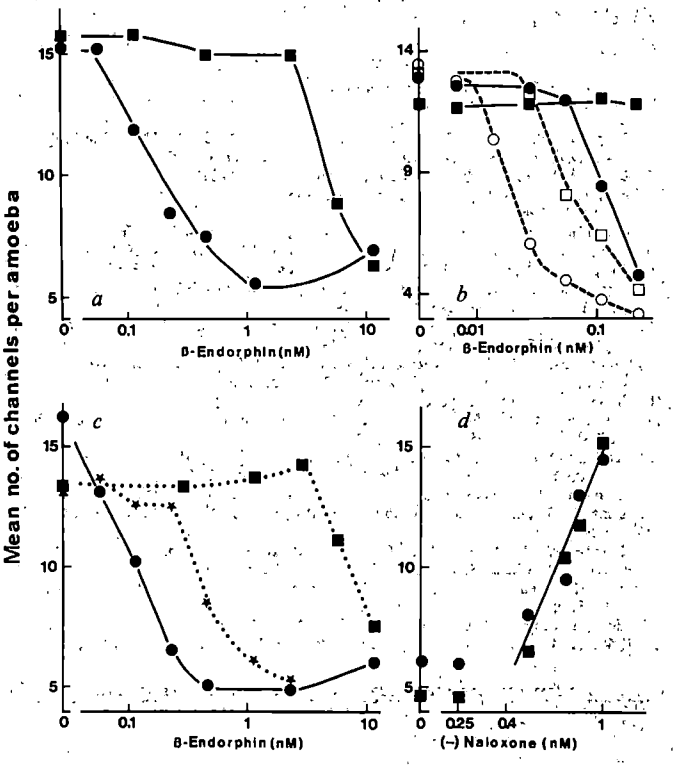

Fig. 3 The effect of Ca^{2+}, verapamil and (−)naloxone on inhibition of pinocytosis by β-endorphin. The inducing salt solutions were as outlined in Fig. 2 legend. *a*, Dose–response curves of β-endorphin (Peninsula Laboratories) on pinocytosis induced by 100 mM Tris-HCl at *p*H 7.0 (●) and by $Tris^+$ plus 10 μM $CaCl_2$ (■). *b*, Inhibition of pinocytosis by β-endorphin is potentiated by verapamil. Pinocytosis was induced by $Tris^+$ (circles) or $Tris^+$ plus 10 μM $CaCl_2$ (squares). Open symbols denote presence of 8×10^{-7} M verapamil. *c*, Comparison between the inhibitory effect of β-endorphin on pinocytosis induced by $Tris^+$ (●), Na^+ (★) or Na^+ plus 10 μM $CaCl_2$ (■). *d*, Reversal of the inhibitory effect of 10 nM β-endorphin by (−)naloxone. Pinocytosis was induced by $Tris^+$ (●) or $Tris^+$ plus 10 μM $CaCl_2$ (■).

An even more significant ionic influence was exerted by Ca^{2+}. In the presence of 10 μM $CaCl_2$ the inhibitory potency of all three opioids was decreased by approximately 90%. This is shown for β-endorphin in Fig. 3*a*. On the other hand, verapamil, which inhibits Ca^{2+} influx in many cells[16], potentiated the response to the opioids and abolished the effect of Ca^{2+} (Fig. 3*b*). Unlike Na^+, Ca^{2+} did not affect the sensitivity to (−)naloxone (Fig. 3*d*) but decreased that to the opioids even when Na^+ was the inducing cation (Fig. 3*c*).

The low concentrations of opioids which affect pinocytosis in *A. proteus* and the enantiomeric stereospecificity of the antagonistic effect of (−)naloxone demonstrated here strongly suggest that these drugs interact at a receptor level. The finding

that the response to opioids in the amoeba is sensitive to Na^+, may reflect conformational changes of the receptor molecule, similar to those which reduce binding of agonists to opiate receptors in nervous tissue[17,18]. Furthermore, the difference in Na^+ sensitivity between Met-enkephalin and morphine in binding to mammalian opiate receptors[19] and inhibition of pinocytosis is similar. The opioids may alter the pinocytotic activity either by reducing the intracellular Ca^{2+} or by decreasing the sensitivity to this ion. Their mode of action may, in fact, be similar to that in synaptosomes, where they are reported to inhibit Ca^{2+} influx[8,20]. However, a physiological function for the opiate receptors in, for example, calcium regulation is difficult to conceive unless ligands for them are discovered in the amoeba itself or in its ecosystem.

We thank Dr A. E. Jacobson, NIAMDD, Bethesda for a gift of (+)naloxone HCl. (−)Naloxone was from Endo. This work was supported in part by grant 14X-0504 from the Swedish MRC.

Adult rat brain astrocytes support survival of both NGF-dependent and NGF-insensitive neurones

Ronald M. Lindsay

Laboratory of Neurobiology, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7, UK

The hypothesis that trophic substances are involved in the normal development and maintenance of the autonomic nervous system has gained much support from studies on the function of nerve growth factor (NGF). *In vitro* at least, both avian and mammalian sensory and sympathetic neurones have a requirement for NGF[1], or for similar, as yet uncharacterised, molecules from homologous non-neuronal cells[2], glial cells[3], glioma cells[4] or homogenates of certain tissues[5]. Although molecules other than NGF can apparently support the *in vitro* survival of apparently NGF-sensitive neurones[4,5], there has been no definitive evidence—excluding preliminary results with parasympathetic neurones of the ciliary ganglion[6–8]—that other specific trophic factors are essential for neurones insensitive to NGF. I report here that adult rat brain astrocytes can promote the *in vitro* survival of not only NGF-dependent neurones, such as rat embryo superior cervical ganglion (SCG) cells, but also NGF-insensitive neurones such as the sensory neurones of the rat or chick embryo nodose ganglion (NG). The support of the NGF-dependent neurones is mediated by astrocyte-derived NGF, whereas the survival of NGF-insensitive neurones is brought about by a diffusible factor quite distinct from NGF, but as yet uncharacterised. Evidence is also presented which indicates that the astrocytes can support two distinct populations of neurones in the chick dorsal root ganglion (DRG). It is suggested that these populations represent respectively the previously described small, late-developing, medio-dorsal, NGF-dependent neurones and the early developing, large, ventro-lateral, NGF-insensitive neurones[9].

Astrocytic glial cells, designated RG18, derived from normal adult rat brain after kainate lesioning of the corpus striatum were maintained as monolayer cultures in 35-mm plastic (Falcon) tissue culture dishes, as previously described[10]. Experimental RG18 were seeded (5×10^3 cells per dish) to give almost confluent monolayers at the start of neuronal–astrocyte co-culture. Rat SCG and NG were from 17–19-d-old embryos, and chick DRG and NG were from 8–9-d-old embryos. Rat ganglia were dissected free of connective tissue, washed twice with Eagle's minimal essential medium (MEM), teased into small chunks and digested with 0.25% trypsin in MEM for 30 min at 37 °C. Chick embryo ganglia required less vigorous trypsinisation—10 min with 0.1%. Trypsinised ganglia were washed three times with MEM, and dissociated into single-cell suspensions by trituration through a finely drawn siliconised glass Pasteur pipette. Cell suspensions were filtered through 45-μm nylon mesh and counted in a haemocytometer. Dissociated neurones were seeded either directly on to the astrocyte monolayer or the astrocytes were first covered, 3–4 h previously, with 1.0 ml of reconstituted rat tail collagen gel[11]. The collagen prevents direct contact of neurones and astrocytes but permits free diffusion between them and the medium. The co-culture growth medium (2 ml per dish) was as previously described[12] with the omission of NGF. Control cultures of all neuronal types were grown on collagen gel (1 ml) coated 35-mm dishes in the presence (5 ng per dish) or absence of NGF purified as before[4]. Parallel experiments were carried out in which anti-NGF antiserum (sheep or rabbit antiserum) was included in amounts of 5–100 μg ml^{-1}. Cultures were maintained in a 5% CO_2: 95% air, humidified atmosphere at 36.5 °C. Growth medium was replenished every third day and co-cultures were maintained for 3 weeks or more.

As shown in Fig. 1, neurones from all the ganglia tested survived and extended long neurites in co-culture conditions. Very few, if any, neurones survived in control conditions, that is, in the absence of either glial cells or exogenous NGF. A modified Holmes silver stain[13] procedure was routinely used to identify neuronal processes (Fig. 1*a–c*), although the large flattened astrocytes are readily distinguished from any neurones even without staining. The survival of SCG and DRG neurones in co-culture could be the result of NGF secretion by the astrocytes. However, this would not explain the survival of nodose ganglion neurones which are insensitive to NGF both in the intact ganglion *in vivo* or *in vitro* (R. Levi-Montalcini, personal communication) and in dissociated culture (R. M. L., unpublished results). Further experiments verified that NGF or an immunologically cross-reactive molecule was being released by the RG18 cells and mediated the survival of the SCG neurones and some of the DRG neurones. Anti-NGF antiserum from two different sources completely abolished the ability of RG18 astrocytes to support the growth of SCG neurones, but only diminished the survival of DRG neurones (Table 1). Increasing the amount of antiserum beyond 5 μg per dish had no further effect on the remaining population of DRG neurones. This clearly suggests that the astrocytes do more than simply support the NGF-sensitive neurones. Nodose ganglion neurones from either chick or rat embryo which survived in

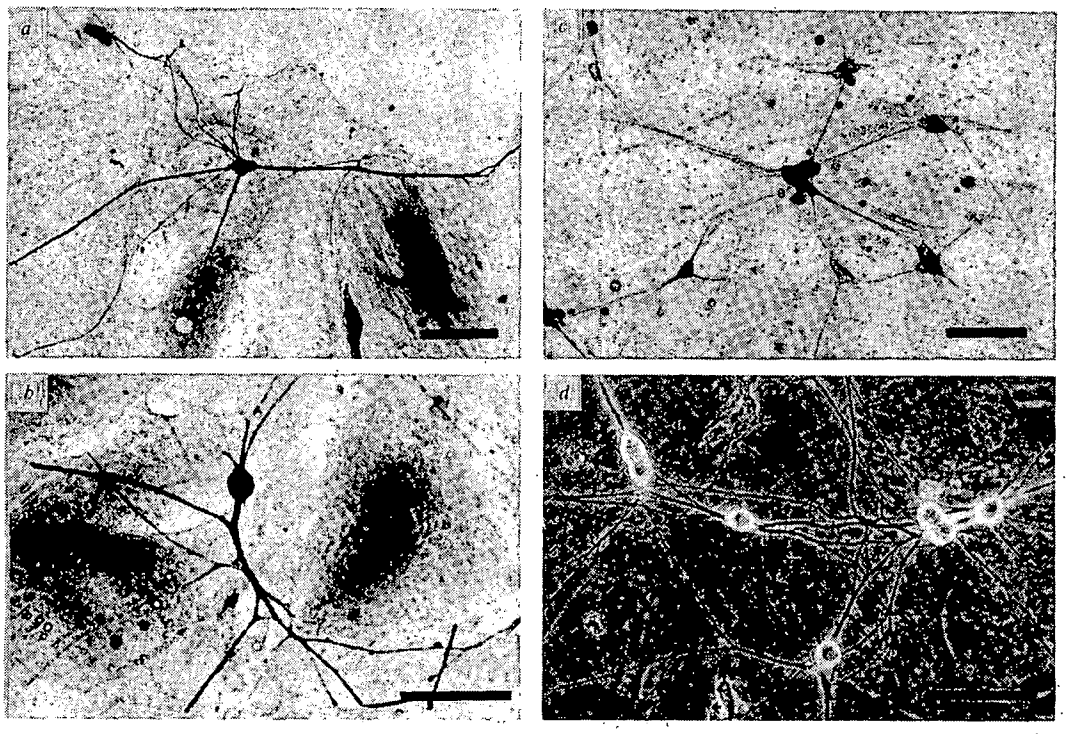

Fig. 1 Dissociated NGF-dependent (SCG, DRG) and NGF-insensitive (NG) neurones surviving in direct contact with adult rat brain astrocytes in the absence of exogenous NGF. Cultures were established as described in the text. *a*, Single rat SCG neurone straddling several RG18 cells, silver stained after 6 d in culture. *b*, Single chick embryo DRG neurone between nuclei of two RG18 cells, silver stained after 6 d *in vitro*. *c*, Network of rat embryo NG neurones on top of astrocyte monolayer, silver stained after 10 d in culture. *d*, Chick embryo NG neurones as seen by phase contrast, unstained preparation after 2 weeks in culture. Calibration bar, 100 μm. Similar observations are obtained when collagen gel is used, but the neuronal fibres extend in three dimensions, making photographic representation difficult.

co-culture with the RG18 cells were completely unaffected by NGF antiserum, as might be anticipated from their insensitivity to NGF *per se*.

To ascertain that the effect of the astrocytes on neuronal survival was not simply the result of a contact phenomenon, co-cultures were established, as described earlier, in which collagen gel was interspaced between the glial monolayer and the neurones seeded on top. Neuronal survival was generally greater when collagen was used (Table 1) than when neurones and glial cells were in direct contact. The gel has no obvious effect on the growth of either cell type.

The number of neurones seeded per dish in these experiments (Table 1) may seem low relative to other studies. The low seeding was initially the result of low yields of nodose ganglion cells after dissociation, but it was later found that low seedings gave more reproducible and more easily quantitated determinations of neuronal survival. However, the low values do not represent a limitation of the astrocytes to support only a few cells, as an increase in the number of neurones seeded gives a proportional increase in neuronal survival (Table 2). The capacity of the astrocyte cultures in this respect has not been fully determined.

Table 1 Influence of adult rat brain astrocytes on the *in vitro* survival of sensory and sympathetic neurones

Growth surface for dissociated neurones	Exogenous NGF (ng per dish)	Anti-NGF antiserum (μg per dish)	Neuronal survival (per 35-mm Petri dish) Rat		Chick	
			SCG	NG	DRG	NG

Cultures were seeded with either 5,000 superior cervical (SCG) or dorsal root ganglion (DRG) cells or 1,000 nodose ganglion (NG) cells per 35-mm dish, prepared as described in the text. Neuronal survival was determined after 6 d in culture, by counting in the phase contrast microscope all neurones with long processes, scanned for in 25% of the culture dish surface. In this typical experiment values represent the mean ± s.e.m. of triplicate dishes, evaluated by two independent counters. NGF was purified and assayed for maximal activity as before[4]. Sheep anti-NGF antiserum at 100 ng ml^{-1} was sufficient to block the activity of 1 ng ml^{-1} NGF. Rabbit anti-NGF antiserum was similarly active, and both antisera were obtained with 2.5S mouse salivary gland NGF. Astrocytes were seeded 1 week before the experiment and coated with collagen gel 3–4 h before neurones were seeded. Not more than 3 h elapsed between the removal of ganglia and the seeding of neurones. Growth medium—MEM, KCl, glucose, uridine, fluorodeoxyuridine and human placental serum[12]—was prepared freshly at each medium change. Human placental serum was obtained from a local hospital and inactivated 30 min at 56 °C before use. The presence or absence of fluorodeoxyuridine did not affect the results: ND, Not determined.

* Sheep antiserum; † rabbit antiserum.

Table 2 Increase in survival of nodose ganglion (NG) neurones with increase in number seeded

Growth surface	Ganglion cells seeded ($\times 10^{-3}$)	Neuronal survival (per 35-mm dish) Rat NG	Chick NG
Collagen	5	8	24
Collagen + NGF (5 ng)	5	31	72
Astrocytes + collagen	5	728	664
Astrocytes + collagen	10	928	736
Astrocytes + collagen	20	1,912	1,624
Astrocytes + collagen	30	4,328	3,104
Astrocytes + collagen	40	5,504	5,752

Cultures were established as described in the text and Table 1 legend. Neuronal survival was determined after 5 d in culture. Values are for single samples only.

The present findings are consistent with the notion that there are molecules analogous to NGF which are essential for the growth and survival of NGF-insensitive neurones. It also supports the role of glial cells in glial–neuronal interactions, and confirms reports that cells of glial origin (glioma[14], glial[15]) are capable of synthesising functionally active NGF. It has previously been shown[9] that not all cells of the DRG are sensitive to NGF and at least two distinct populations of neurones have been identified in the ganglion by this and other criteria. The present results indicate that astrocytes are capable of promoting survival of not only the NGF-dependent neurones (the small mediodorsal cells) but also some NGF-insensitive neurones. This is borne out by the observation that anti-NGF antiserum can diminish but is unable to abolish the ability of astrocytes to support DRG neurones in co-culture (Table 1). The developmental similarity between the large neurones of the nodose ganglion and the large, ventro-lateral, NGF-insensitive neurones of the DRG suggests that these latter neurones survive in astrocyte co-culture and that it is their survival which is unaffected by anti-NGF antiserum. Verification of this latter point by biochemical and immunohistological analyses of the surviving cells in different conditions is in progress.

It will be interesting to determine through cell selection procedures whether a single astrocyte from the RG18 cultures is capable of synthesising more than one neuronal growth factor, or whether the ability to synthesise NGF and the ability to support the survival of NGF-insensitive neurones reside in different glial cell types. It will also be interesting to establish if there is any connection between the results of this study and previous reports of non-NGF neuronal growth-promoting activity in glioma cultures[4] or homogenates of certain tissues[5].

I thank Janice Tarbit for technical assistance. Initial RG18 cells were obtained from Drs V. J. Singh and D. Van Alstyne, and sheep and rabbit antiserum were obtained from Drs Y. A. Barde and P. Calissano, respectively.

Onset of neural function in the lateral line

D. McG. Zimmerman

Department of Biology, University of California, San Diego, La Jolla, California 92093

The development of the nervous system includes the formation of specific neuronal connections. Some insight into the mechanisms by which these connections are made may be obtained by determining the order in which the elements of a developing system begin to function and examining any changes that may occur in the system shortly after it begins functioning. I have investigated the lateral line of the South African clawed frog, *Xenopus laevis* and I have classified the afferent system into three elements. First, the transduction mechanism, which includes all components that couple the water vibrations to the release of transmitter from the hair cell. Second, the afferent synapse, at which there is transmitter release and subsequent postsynaptic conductance changes. And third, the afferent axon. I report here experiments suggesting that these elements become functional in the following order: first, the axon can conduct action potentials; second, transmission is established; third, the transduction mechanism can modulate transmitter release. This same sequence has been reported in a system related to the lateral line, the auditory pathway of mammals[1].

The peripheral lateral line basically consists of many clusters (neuromasts) of hair cells and a nerve connecting these sensory cells to the brain[2]. Two afferent nerve fibres innervate a neuromast; each connects with half of the hair cells, all of which are orientated in the same direction and opposite to those synapsing on to the other fibre. The hairs project into the water environment and sense aqueous vibrations. In addition, there are efferent fibres which make inhibitory synapses on to the hair cells[3]. At the earliest developmental time (26 days stage 34 (ref. 4)) when electrical activity in the lateral-line nerves of *Xenopus* tadpoles has been examined it has been essentially adult in character[5], indicating that the developmental events mentioned above are completed by that time. The experiments reported here were carried out on *Xenopus* tadpoles between the ages of 2 days 8 h (NF 38) and 6 days (NF 48) after fertilisation of the egg (timing accurate to within 2 h). The animal was immersed in saline (3 mM KCl, 10 mM $CaCl_2$, 125 mM NaCl, 5 mM Tris-HCl, *p*H 7.3–7.4), anaesthetised by chilling to 1 °C,

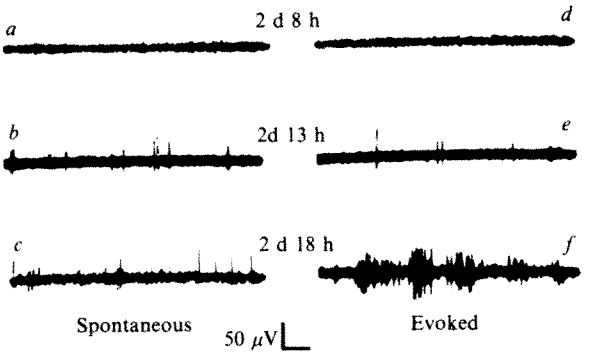

Fig. 1 Electrical activity recorded from lateral-line nerve at three ages. *a–c*, No stimulus: *d–f*, gross stimulation. *a*, *d*, 2 d 8-h-old animal. *b*, *e*, 2 d 13-h-old animal. *c*, *f*, 2 d 18-h-old animal. Records from three different animals. Of five animals recorded from at 2 d 13 h exhibiting spontaneous activity, none had evoked activity. Of five animals recorded from at 2 d 18 h, all had both spontaneous and evoked activity. Horizontal scale, *a*, *c*, *d*, *f*, 0.1 s; *b*, 0.5 s; *e*, 0.2 s.

immobilised, the spinal cord transected and the brain removed. Nomarski optics were used to visualise the lateral-line nerve, the neuromasts and individual hairs (kinocilia). Removing a window of skin allowed a recording suction electrode to be applied to the post-orbital lateral-line nerve, either to its cut end or *en passant*, near its entry to the brain. Electrical activity in the nerve was recorded using standard electrophysiological techniques. Three modes of stimulation were used: (1) gross stimulation, a gentle rocking of the preparation table which caused the saline to flow back and forth across the tadpole, exciting many neuromasts; (2) a mechanical stimulation applied to single neuromasts, as described below; and (3) direct electrical stimulation of the nerve by passing current pulses through a stimulating suction electrode. All experiments were done at room temperature (20–22 °C).

The onset of sensory transmission by the afferent nerve was determined by recording from animals of different ages (Fig. 1). At 2 days 8 h, neither spontaneous nor evoked activity was seen, even though the nerve was capable of conducting impulses in response to electrical stimulation (Fig. 2).

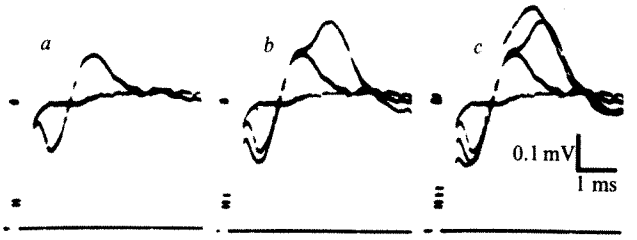

Fig. 2 Direct electrical stimulation of lateral-line nerve in 2 d 8-h-old animal with four current pulses, one every 15 s, delivered by a stimulating suction electrode. Top traces, evoked compound action potentials. Bottom traces, stimulating pulses. *a*, First two trials, superimposed, *b*, first three trials; *c*, all four trials. The fast and slow components, most easily seen in *b*, may correspond to afferent and efferent fibres, respectively.

The appearance of spontaneous activity at $2\frac{1}{2}$ days (Fig. 1*b*, *e*) suggested that transmission begins at that time. The chemical sensitivity of the synapse offers a method of determining the origin of the spontaneous activity and testing this point. Chemicals suspected of being the afferent transmitter, L-glutamate[6] (L-Glu) and L-γ-aminobutyric acid[7] (GABA), were introduced into the saline to see if either would diffuse to the junction and stop activity by desensitising the postsynaptic receptors[8,9]. The efferent synapse on to the hair cell is likely to be cholinergic[10] and would not be affected by these substances. Exposure to 1 mM L-Glu reversibly abolished spontaneous and evoked activity in animals old enough to exhibit evoked activity (Fig. 3). Spontaneous activity in younger animals was similarly eliminated. The activity usually increased shortly after introduction of L-Glu and only after several minutes fell to zero (data not shown). This pattern of activity, characteristic of desensitisation[6], was not seen when equal concentrations of GABA or a control, D-Glu, were substituted for L-Glu. The diffusion path is not known but may include passage through holes made in the skin during dissection. These results not only suggest that the afferent transmitter is L-Glu, but also indicate that the spontaneous activity arises at the junction. This interpretation is consistent with the proposal of Harris and Flock[2] that the spontaneous activity in adult *Xenopus* lateral line is caused by transmitter release and not a pacemaker potential. It remains to be determined whether the final component of transmission is the release of transmitter, the apposition of the pre- and postsynaptic membranes, or the appearance of a sufficient postsynaptic response.

At 2 days 18 h, gross stimulation evoked a vigorous response (Fig. 1*f*) in contrast to its apparent lack of effect at 2 days 13 h (Fig. 1*e*). The onset of sensory function occurs, therefore, at roughly $2\frac{3}{4}$ days. As gross stimulation does not affect synaptic transmission until this time, I conclude that the transduction mechanism is the last of the three afferent elements to function.

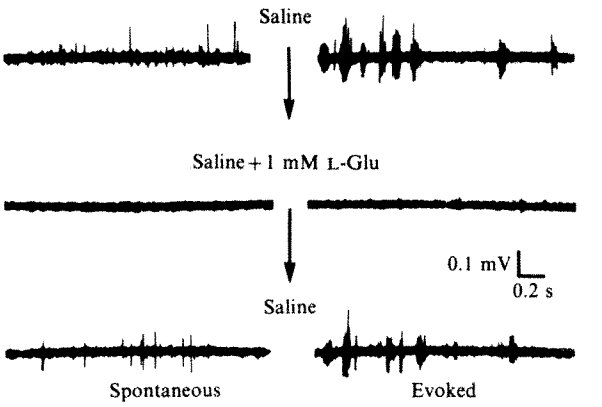

Fig. 3 Glutamate sensitivity of the lateral line in 3 d 15-h-old animal. Left records, no stimulus. Right records, gross stimulation. Top, before addition of L-Glu. Middle, 7 min, after 1 mM L-Glu (*p*H 7.4) introduced to the bath. Bottom, 9 min after wash and return to normal saline. The L-Glu concentration is comparable to that needed to desensitise Mormyrid lateral line[6] and may be necessary due to the diffusion barrier surrounding the synapse. Four out of five animals tested before the age of 3 d 10 h showed the response. After that age the system showed decreasing sensitivity to L-Glu, possibly because the diffusion path becomes progressively more impermeable with age.

Developmental changes in the sensory response of the system were studied by means of a mechanical stimulator which provided a one-dimensional controlled movement of 2–20 μm in response to an applied voltage. The sensitivity of single neuromasts was investigated by orientating the stimulator in the direction of maximum sensitivity of the neuromast[5], placing it in contact with the hairs ~10 μm above the skin surface, and vibrating it to evoke activity from that neuromast. In examination of 50 neuromasts from 18 animals, both units were often seen to respond, one to each phase of the stimulus. The sensitivity of the system increased substantially between 2 days 18 h and 6 days. For example, an equivalent response to 10 cycles of 100 Hz sinusoidal stimulation was elicited at 6 days by a stimulus whose amplitude was only 20% of that required at $2\frac{3}{4}$ days. At the onset of sensory function the system was not able to follow a 200-Hz stimulus, whereas at 6 days, it followed frequencies greater than 350 Hz. The average kinocilium length at $2\frac{3}{4}$ days is ~50% what it is at 6 days.

It seems that the nerve is the first element to function, capable of conducting action potentials before 2 days 8 h after fertilisation. Second, transmission begins at approximately $2\frac{1}{2}$ days. Third, at $2\frac{3}{4}$ days, the transduction mechanism operates, and sensory function begins, approximately 1 day after responses have been found to dimming the illumination of the pineal eye[11], and 1 day before the first tectal activity evoked by ocular stimulation with light flashes[12]. The sensitivity of the peripheral lateral line increases greatly during the next 4 days. The development of the efferent system has yet to be studied. The efferent axons may be functional before 2 days 8 h. The onset of synaptic inhibition of the hair cells has not yet been determined.

The fact that transmission begins before the transduction mechanism is established implies that this connection is formed without benefit of sensory information. In addition, the first few hours activity carried by the afferent fibres seems to be only spontaneous and unmodulated. It will be interesting to ascertain whether these first connections are altered as the animal develops further.

This work was supported by grants to N. Spitzer from the NSF and NIH. I thank Dr Spitzer for his guidance and encouragement.

Equivalence of Ca^{2+} and Sr^{2+} in transmitter release from K^+-depolarised nerve terminals

Alan M. Mellow

Laboratory of Presynaptic Events, Department of Pharmacology, Northwestern University Medical School, Chicago, Illinois 60611

Depolarisation–secretion coupling at presynaptic nerve terminals is thought to be mediated by the influx of calcium ions from the extracellular fluid through voltage-sensitive channels in the nerve terminal membrane[1]. In physiological conditions, the depolarisation is accomplished when the nerve action potential invades the nerve-ending. At the neuromuscular junction, the nerve impulse promotes the synchronous release of many quanta of the transmitter, acetylcholine, the response to which is recorded postsynaptically as the endplate potential (e.p.p.)[2]. Strontium can substitute for Ca^{2+} in the support of transmitter release evoked by nerve impulses[3–5], although it is far less effective (on a molar basis) in the generation of the e.p.p. It has been suggested[5] that Sr^{2+} may be less accessible from the extracellular fluid during the action potential, and might not achieve as high a concentration as Ca^{2+} in the nerve ending so that it would seem less effective. Alternatively, intra-terminal releasing sites may exhibit true selectivity for divalent cations. To help distinguish between these possibilities, I have made use of the long-established observation that when nerve terminals are depolarised by elevating the extracellular potassium ion concentration ($[K^+]_o$), there is a dramatic increase in the frequency of spontaneous miniature endplate potentials (m.e.p.ps)[6–9]. This is thought also to be a form of depolarisation–secretion coupling (that is, mediated by Ca^{2+} entry through voltage-gated channels), though of relatively long duration. I have compared the relative abilities of Ca^{2+} and Sr^{2+} in supporting the augmented m.e.p.p. frequency seen in high K^+ Ringer's solutions and report here that they are qualitatively and quantitatively equivalent, in contrast to their differences in the nerve impulse-evoked e.p.p.

All experiments were carried out on the isolated cutaneous pectoris nerve–muscle preparation of the frog (*Rana pipiens*). Conventional electrophysiological techniques were used for intracellular recording of m.e.p.ps from single endplates. Preparations were washed initially in a standard Ringer's solution of the following composition (mM): NaCl 115, KCl 2, $NaHCO_3$ 6, $CaCl_2$ 1.8; *p*H 6.9–7.2. Before the beginning of an experiment, a preparation was washed for at least 1 h in divalent cation-free Ringer's solution[5]. It was then treated with a Ringer's solution which contained 11 mM KCl and to which were added appropriate amounts of $SrCl_2$ or $CaCl_2$. All solutions contained neostigmine methylsulphate (1 μg ml^{-1}), to increase m.e.p.p. amplitudes. In those experiments where the concentration of divalent cation was varied, osmolarity was maintained constant by substitution of 2.5 mM sucrose for every 1 mM $SrCl_2$ or $CaCl_2$ (ref. 10). The frequencies of m.e.p.ps were determined in a given solution by recording m.e.p.p.s for successive 1-, 2- or 10-s intervals. At least 30 intervals were recorded, from which the mean m.e.p.p. frequency was calculated. Only data from those junctions where the m.e.p.p. frequency in a given solution was relatively stable over time were included in the experimental results.

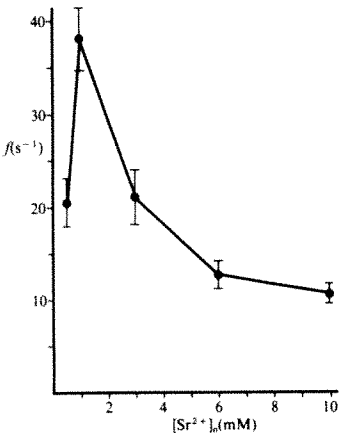

Fig. 1 Effects of $[Sr^{2+}]_o$ on m.e.p.p. frequency (f) at a single endplate in Ringer's solution containing 11 mM K^+. Each point represents the mean ± s.e.m. of 30 1-s counts at a given $[Sr^{2+}]$. The osmolarity was kept constant throughout the experiment by addition of appropriate amounts of sucrose to the Sr^{2+}-Ringer (see text).

Figure 1 shows the results of an experiment in which the effect of external Sr^{2+} concentration ($[Sr]_o$) on m.e.p.p. frequency in 11 mM K^+ Ringer's solution was studied. In this experiment, the m.e.p.p. frequency increased between 0.5 mM Sr^{2+} and 1.0 mM Sr^{2+} and then declined progressively as the $[Sr^{2+}]_o$ was raised, up to 10 mM. This non-monotonic dose–response curve is quite similar to that found previously with Ca^{2+} in similar conditions[8,9,11]. For example, Matthews and Wickelgren found that the relationship between $[Ca^{2+}]_o$ and m.e.p.p. frequency in high K^+ solutions reached a peak at about 1–3 mM Ca^{2+} and declined at concentrations greater than 3 mM. These authors suggested that the inhibitory effects of high Ca^{2+} are due to its screening of the membrane surface charge, with consequent membrane hyperpolarisation and inactivation of voltage-sensitive Ca^{2+} channels. The qualitatively similar behaviour of Sr^{2+} is consistent with such a screening hypothesis, because Sr^{2+}, as a divalent cation, would also be effective in screening the membrane surface charge and in closing down voltage-gated Ca^{2+} channels[12,13]. The question remains, however, as to whether the response mediated by Sr^{2+} is quantitatively similar to that of

Table 1 Comparison of the effects of Ca^{2+} and Sr^{2+} on m.e.p.p. frequency in 11 mM K^+ Ringer's solution

Experiment no.	$[Me^{2+}]$ (mM)	$f_{Ca}(s^{-1})$	$f_{Sr}(s^{-1})$	f_{Ca}/f_{Sr}
1	0.5	5.7 ± 0.5	5.2 ± 0.7	1.10
2	0.5	3.9 ± 1.0	4.7 ± 0.9	0.83
3	0.5	6.8 ± 1.9	5.4 ± 1.2	1.26
4	2.0	22.3 ± 3.0	20.9 ± 3.1	1.07
5	2.0	13.8 ± 1.9	13.7 ± 2.4	1.01
6	5.0	13.9 ± 3.0	15.3 ± 3.2	0.91
7	5.0	5.6 ± 1.1	5.7 ± 1.3	0.98
8	5.0	5.2 ± 0.9	5.6 ± 1.1	0.93
9	7.0	13.4 ± 2.0	12.9 ± 1.7	1.04
10	10.0	2.7 ± 0.7	2.4 ± 0.5	1.12
11	10.0	7.7 ± 1.2	8.2 ± 1.2	0.94
				Mean = 1.02

The m.e.p.p. frequency at a given $[Ca^{2+}]$ (f_{Ca}) was compared at the same endplate with that in equimolar $[Sr^{2+}]$ (f_{Sr}); f_{Ca}/f_{Sr} represents the ratio of the two values, which in no case differs appreciably from unity. Each f value represents the mean ± s.e.m. of 30 successive counts of 2 s duration in experiments 1, 2, 3, 7, 8, 10 and 11 and of 1 s duration in experiments 4, 5, 6 and 9. For each experiment, $[Me^{2+}] \equiv [Ca^{2+}]$ or $[Sr^{2+}]$. Data are presented from 11 different preparations. Note that although there is considerable variation among preparations, the basic non-monotonic trend with respect to divalent cation concentration is evident. This trend is more clearly shown for Sr^{2+} in Fig. 1 and for Ca^{2+} in ref. 9.

Ca^{2+}, over the concentration range studied in the above experiment. To answer this question, several experiments were carried out in which the m.e.p.p. frequency in high K^+ Ringer's solution containing Ca^{2+} was compared at the same endplate with that in a solution containing equimolar Sr^{2+}. Figure 2 shows a record of such an experiment in which m.e.p.p. frequencies were recorded continuously for approximately 85 min. When the preparation was bathed in a Ringer's solution containing 0.5 mM Ca^{2+} and 2 mM K^+, the mean m.e.p.p. frequency recorded over about 5 min was $1.2 \pm 0.2\ s^{-1}$ (mean ± s.e.m.). When the $[K^+]_o$ was raised to 11 mM, the m.e.p.p. frequency increased to $24 \pm 3\ s^{-1}$. When the bathing solution was changed to one containing 0.5 mM Sr^{2+} (in 11 mM K^+), the m.e.p.p. frequency remained at the same level ($23 \pm 2\ s^{-1}$). On returning to 0.5 mM Ca^{2+}, 11 mM K^+, the m.e.p.p. frequency was again maintained ($25 \pm 2\ s^{-1}$). Finally, when $[K^+]_o$ was reduced again to 2 mM, the m.e.p.p. frequency returned to the control level ($1.4 \pm 0.2\ s^{-1}$). This experiment suggests that at equimolar concentrations, the two ions are equally capable of supporting the increased m.e.p.p. frequency evoked by high $[K^+]_o$. Table 1 presents a summary of experiments done on 11 other preparations in which the two ions were compared in concentrations of 0.5–10 mM. It can be seen that, although there is some variation among preparations, there is essentially no difference between Ca^{2+}-activated and Sr^{2+}-activated transmitter release.

The depolarisation of the nerve membrane produced by treatment with high K^+ is a sustained event, as it is determined primarily by the Nernst equilibrium potential for K^+ (ref. 14).

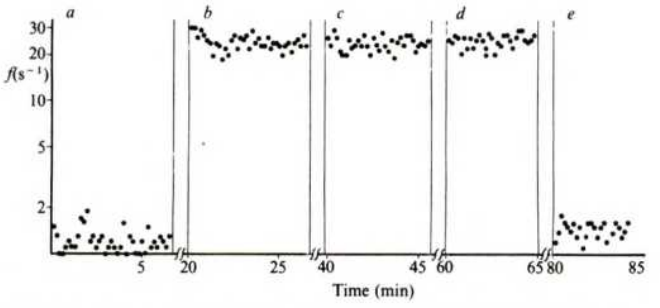

Fig. 2 Augmentation of m.e.p.p. frequency (f) by high $[K^+]_o$ in Ca^{2+} and Sr^{2+} Ringer's solutions. Continuous recording of m.e.p.ps over about 85 min. Each point represents the m.e.p.p. frequency over a 10-s counting interval. Note the logarithmic scale on the ordinate axis. An equilibration time of approximately 15 min for each solution change was allowed before data were collected. *a*, The control frequency (in 0.5 mM Ca^{2+}, 2 mM K^+) was $1.2 \pm 0.2\ s^{-1}$ (mean ± s.e.m.). *b*, In 0.5 mM Ca^{2+}, 11 mM K^+, the frequency increased to $24 \pm 3\ s^{-1}$. *c*, In 0.5 mM Sr^{2+}, 11 mM K^+, the frequency was $23 \pm 2\ s^{-1}$. *d*, On returning to 0.5 mM Ca^{2+}, 11 mM K^+, the frequency remained constant ($25 \pm 2\ s^{-1}$). *e*, On return to the control solution (0.5 mM Ca^{2+}, 2 mM K^+), the m.e.p.p. frequency returned to $1.4 \pm 0.2\ s^{-1}$.

This is distinguished from the depolarisation which occurs during the nerve impulse in that the latter is of short duration (of the order of 1 ms) and therefore allows only a transient increase in Ca^{2+} (or Sr^{2+}) permeability. During this brief event, Sr^{2+} might have a lower mobility in the ionic channel and therefore might not enter the terminal and gain access to the intra-terminal releasing sites to the same extent as Ca^{2+}. In contrast, high K^+ provides a prolonged depolarisation to the nerve ending and as Ca^{2+} channels at the presynaptic membrane probably do not exhibit time-dependent inactivation[15–17], this depolarisation provides a steady-state, long-lasting increase in Ca^{2+} (or Sr^{2+}) permeability. This prolonged event might allow enough time for Sr^{2+} to accumulate at release sites to the same extent as Ca^{2+}. In these conditions, a difference between the two ions might reflect true intracellular ionic selectivity. The experiments described above, however, indicate that when ion entry factors are minimised (by a prolonged increase in permeability), the differences between Ca^{2+} and Sr^{2+} as supporters of transmitter release disappear. This suggests that there is divalent cation non-selectivity at intra-terminal releasing sites. Further support for this view comes from a recent report[18] in which transmitter release was studied in neuromuscular preparations treated with tetrodotoxin and 4-aminopyridine to block the nerve action potential. In these conditions, brief electrotonic depolarisation of the nerve ending seems to trigger a regenerative, 'all-or-none' Ca^{2+} current presynaptically[19] and evoke a giant (>70 mV) e.p.p. postsynaptically. Equimolar substitution of Sr^{2+} for Ca^{2+} gave an e.p.p. of identical amplitude. Thus, even in conditions of brief applied depolarisation, Ca^{2+} and Sr^{2+} seem to be equivalent as supporters of transmitter release, when, as in this case, it is presumed that a maximal ion flux was generated and entry into the nerve terminal ceased to be a limiting factor.

In conclusion, the results of these experiments support the notion that the relatively low efficiency of Sr^{2+} in substituting for Ca^{2+} in nerve impulse-evoked transmitter release does not reflect true intracellular ionic selectivity. Instead, it is probably related to a phenomenon of reduced access of Sr^{2+} to the nerve terminal cytoplasm, because in conditions in which such access ceases to be a limiting factor, the difference in efficiency is abolished.

I thank Dr E. M. Silinsky for his advice and friendship throughout this work, and for his assistance in the preparation of this manuscript. This study was supported by NIH grant NS 12782 to Dr E. M. Silinsky.

Agonist-induced potentiation of acetylcholine sensitivity in denervated skeletal muscle

A. J. Harborne & Margaret E. Smith

Department of Physiology, University of Birmingham, Edgbaston, Birmingham, UK

The entire surface membrane of denervated skeletal muscle is sensitive to the neuromuscular transmitter, acetylcholine (ACh), whereas in innervated muscle only the junctional area is sensitive. It has been proposed that this difference is due to a 'trophic' effect exerted by ACh in innervated muscle to keep the extrajunctional regions of the surface membrane insensitive to its depolarising action[1]. Several studies[2–4] have demonstrated an agonist-induced potentiation of ACh sensitivity, followed by desensitisation, at the endplate region of normal muscles. The potentiation has been attributed to a cooperative action of ACh on the receptors[3]. Desensitisation of the extrajunctional regions of denervated muscles by ACh has also been described[5]. We now provide evidence that the transmitter itself potentiates the ACh contracture and depolarisation responses of the denervated muscles of the rat *in vitro* and that it produces this effect by increasing the number of available ACh receptors on the surface membrane.

We used the slow soleus and the fast extensor digitorum longus (EDL) muscles of rats of 100–150 g body weight which had been denervated 4–6 days previously. Muscle contracture and membrane depolarisation responses to diffuse application of ACh were used to test the chemosensitivity of the muscles[6,7]. The contracture reponses to ACh (10^{-6} kg l^{-1}) increased with successive applications of the drug, reaching a maximum after 60–100 min. Figure 1 shows the results from a typical experiment. The maximum increases observed were three to nine times greater than the initial responses to the same dose of ACh ($n = 9$). The magnitude of the twitch tension elicited by supramaximal electrical stimulation remained unchanged throughout the experiment. When carbachol was used to elicit contractures the responses again increased with successive applications of the drug. Carbachol is a cholinergic agonist which is not inactivated by cholinesterases; thus, the increases in the response are not due to inactivation of acetylcholinesterase.

The increases in the contracture reponses with time of incubation were due to a potentiating action of ACh, as when muscles were incubated in Krebs–Henseleit solution for 100 min before ACh application, they exhibited contracture reponses immediately after the preincubation which were comparable in magnitude to the initial responses of muscles which had not been preincubated. Furthermore, the responses of the preincubated muscles increased with successive ACh applications and the time course of the increase was similar to that seen with muscles which had not been preincubated (Fig. 1). As all muscles were stimulated electrically throughout the experiments, including the preincubation period, the ACh potentiation of the contracture responses was not a consequence of muscle contraction.

To determine whether the potentiation of the contracture response was due to an action on the membrane, we measured the depolarisation of the extrajunctional membrane in response to repeated application of ACh (10^{-7} kg l^{-1}) in 4- and 5-d denervated soleus muscles. The depolarisation responses, like the contractures, increased with successive ACh applications, reaching a maximum after 60–100 min (Fig. 2). No significant changes in the resting membrane potential were recorded during the experiments. Values of 65.3 ± 0.8 mV (30 fibres) were recorded before the first application of ACh and 64.3 ± 1.2 mV (30 fibres) after 120–150 min incubation.

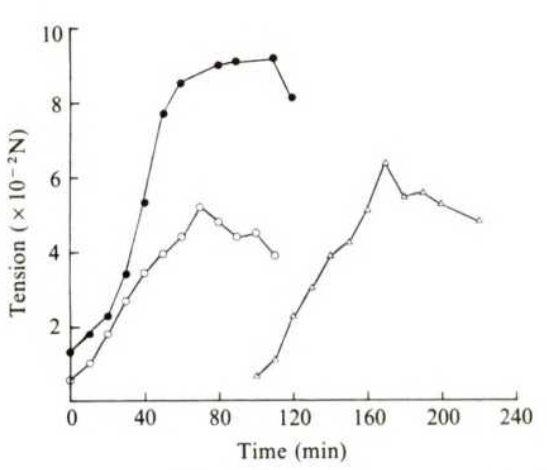

Fig. 1 Potentiation of the ACh contracture responses in denervated muscles. The soleus and EDL muscles of rats denervated 4–6 d previously by unilateral section of the sciatic nerve[6], were dissected out under ether anaesthesia and suspended in an organ bath containing Krebs–Henseleit solution. All muscles were stimulated electrically at 0.1 Hz and supramaximal intensity throughout the experiment. The initial resting tension was adjusted so that the electrical stimulation produced the maximum contracture. The contractures in response to 10^{-6} kg l^{-1} ACh were recorded as described previously[6]. The drug was removed each time by washing the muscle with 10 bath volumes of Krebs–Henseleit solution. ●, EDL; ○, soleus; △, soleus. In this case ACh application was started at 100 min but electrical stimulation was started at zero time.

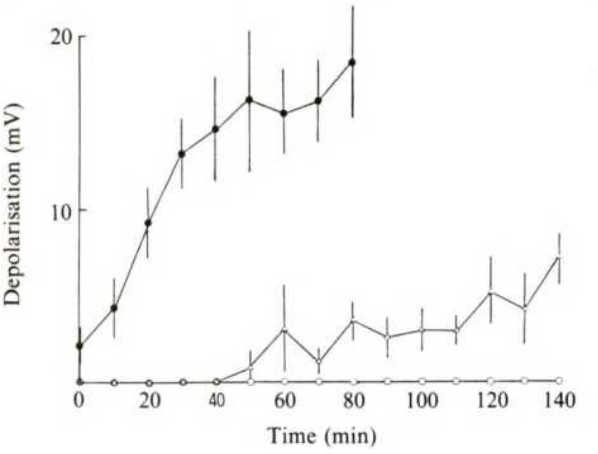

Fig. 2 Effect of ACh on the membrane depolarisation responses of denervated soleus muscles. The resting membrane potential and membrane depolarisation responses to ACh were measured as described previously[7]. Muscles were pinned in an organ bath in Krebs–Henseleit solution and fibres impaled with conventional 3 M KCl-filled micropipettes[12] at extrajunctional regions 2–4 mm from the distal tendons. ACh (10^{-7} kg l^{-1}) was applied diffusely at 10-min intervals, and the drug was removed by washing the muscles with 10 bath applications of Krebs–Henseleit solution. ●, Unblocked muscles ($n = 8$); △, muscles blocked with BTX and then treated with ACh (10^{-5} kg l^{-1}) at 10-min intervals ($n = 5$); ○, control muscles pretreated with ACh (10^{-7} kg l^{-1}) until no further increases in response were seen (10 applications) and then blocked with BTX and treated again with ACh (10^{-5} kg l^{-1}) at 10-min intervals ($n = 5$). Blockade of receptors was effected by incubation of muscles with 0.01 g l^{-1} BTX for 1 h followed by continuous washing with Krebs–Henseleit solution for a further 1 h to remove excess toxin . Values are given as the means with the s.e.m.

To investigate whether the increases in the membrane depolarisation response were due to an increase in the number of receptors available to react with ACh, the effect of the transmitter on muscles blocked with α-bungarotoxin (BTX) was studied. This toxin binds almost irreversibly with ACh receptors[8]. We first established that all available receptors could be blocked, by treating denervated control muscles with ACh until the maximum depolarisation response had been observed, and then incubating the same muscles with the toxin. Such muscles showed no response to ACh subsequently applied at 10-min intervals over 120 min. On the other hand, muscles blocked with BTX in the same conditions but without prior treatment with ACh subsequently exhibited a depolarisation in response to ACh. No responses were seen with the first few applications of the drug but with subsequent applications there was a progressively increasing response (Fig. 2). The new responses were dependent on ACh treatment, as BTX-blocked muscles which were washed for 4 h before ACh applications were insensitive to the first two to four applications of the drug, although small responses were seen with subsequent applications ($n = 4$). The new response could be blocked with BTX in the same conditions as before.

Other workers[9] have demonstrated an increasing contracture response in denervated rat diaphragm blocked with BTX and proposed that BTX alters the membrane architecture, thereby initiating the incorporation of new ACh receptors into the membrane; however, these workers found no effect of ACh on this process. In the present study, the increases in the response in soleus and EDL muscles could be demonstrated regardless of whether or not the muscles had been blocked, and the potentiation was dependent on ACh treatment.

Muscles which have been desensitised by ACh have been reported to bind less BTX than muscles which have not been

treated with ACh[10]. Although it is unlikely that agonist-desensitised receptors are present initially in denervated muscles in view of the absence of ACh and the spontaneous reversibility of this type of desensitisation, it is possible that some receptors are initially held in an inactive conformation, unable to bind BTX or ACh, and can be activated by some action of ACh on the muscle membrane. On the other hand, pools of receptors, possibly of a precursor nature and inaccessible to BTX binding, have been demonstrated in other muscles[11]. Thus, it is possible that the potentiating effect of ACh on muscle chemosensitivity is due to an increase in the number of receptors available to react with ACh or BTX by exposure of previously masked receptors or an incorporation of preformed receptors or receptor precursors into the muscle surface membrane.

Intracellular *p*H and the sodium requirement at fertilisation

Sheldon S. Shen & Richard A. Steinhardt

Department of Zoology,
University of California, Berkeley, California 94720

Several lines of evidence suggest that ionic messengers are primary agents in the metabolic derepression which occurs at fertilisation. The derepression at fertilisation or parthenogenetic activation of the sea urchin egg occurs in two main phases. The first phase, which triggers the early events of fertilisation, is mediated by transitory increase of intracellular free calcium[1–3]. The second, which triggers the late events of fertilisation, is mediated by a rise in the intracellular *p*H (refs 4–6). The transition from the early events of fertilisation of sea urchin eggs to the late events requires a minimal concentration of sodium in the external medium[7]. External Na^+ is required for the acid efflux which follows fertilisation[8]. Na^+ requirement and the acid efflux have been correlated in a hypothesis which proposes that internal protons are exchanged for external Na^+ (refs 8, 9). By using *p*H-sensitive microelectrodes, we have examined the relationship between external Na^+ and internal *p*H more closely. We demonstrate here that the increase of the intracellular *p*H following egg activation does require external Na^+. However, the relative insensitivity of the alkalisation of the egg cytoplasm to large reductions of external Na^+ is evidence against the Na–H exchange hypothesis.

Intracellular *p*H was measured using Thomas-type, *p*H-sensitive microelectrodes with recessed-tips[10]. The calibration and use of these electrodes for sea urchin eggs have been described[11]. As fertilisation by sperm is difficult in the complete absence of sodium[12], we activated the eggs with the calcium ionophere, A23187 (ref. 1). Figure 1 illustrates the change of the intracellular *p*H of unfertilised eggs of *Lytechinus pictus* exposed to A23187 in natural seawater. The alkalisation induced by ionophore activation is similar to that of fertilisation[6]. When eggs were activated by A23187 in Na^+-free artificial seawater (ASW, choline substitution), the elevation of the fertilisation membrane was observed; however, the rise of the internal *p*H did not occur (Fig. 1). When external Na^+ was added back (arrow, Fig. 1), the ctyoplasm underwent alkalisation. Thus, the elevation of cytoplasmic *p*H associated with activation of the egg required external Na^+.

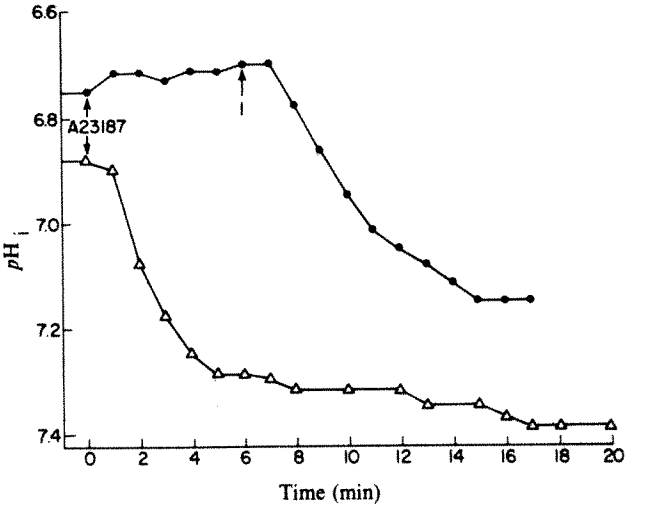

Fig. 1 The external Na^+ requirement for alkalisation after egg activation. In all experiments, the *Lytechinus pictus* egg was impaled with two microelectrodes, The egg membrane potential was measured by a conventional microelectrode filled with 3 M KCl. The *p*H-sensitive microelectrode recorded the membrane potential and a voltage proportional to *p*H. Both electrode measurements were continuous and recorded on separate channels of a Gould-Brush Mark 220 chart recorder. To obtain the intracellular *p*H (pH_i), the membrane potential was subtracted from the *p*H microelectrode potential at intermittent points. Care was taken to assure that any fluctuations of the internal *p*H was plotted. The noise of the recordings was less than 200 μV. The *p*H-sensitive electrode was calibrated in 100-mM phosphate buffers (*p*H 6.5 and 7.5) before and after each experiment. The full response times of these electrodes were 30 s or less. The *p*H of natural seawater (SW) was adjusted with 1 M HCl or NaOH. Artificial seawater (ASW) had the following composition in mM: NaCl, 480; KCl, 10; $CaCl_2$, 5.5; $MgSO_4$, 29; $MgCl_2$, 27; $NaHCO_3$, 5. The *p*H was adjusted with 1 M HCl or NaOH. The temperature was 16–18 °C in all experiments. The activation of eggs by A23187 was in SW, *p*H 8 (△) and in Na-free ASW, *p*H 8 (●). Na-free ASW was made with choline chloride substitution for NaCl, reduction of KCl to 5 mM and $KHCO_3$ substitution for $NaHCO_3$. *p*H was adjusted with 1 M HCl or KOH. At the arrow, ASW was added to the bath to raise the external Na^+ to 80 mM.

It has been reported that amiloride (an inhibitor of passive Na^+-entry into many Na^+-transporting epithelia[13,14]) at 10^{-4} M could block 80% of the acid efflux associated with fertilisation of *Strongylocentrotus purpuratus* eggs when the external Na^+ was reduced to 50 mM (ref. 8). We tested the effects of low external Na^+ and the presence of amiloride on the changes of the intracellular *p*H after fertilisation of *L. pictus* eggs. The addition of 0.5 mM amiloride to 50 mM Na^+-ASW (choline substitution) did not have any apparent effect on cell division of fertilised eggs. However, inhibitory effects of amiloride in 25 mM Na^+-ASW were observed. Amiloride at 10^{-4} M in 25 mM Na^+-ASW did not inhibit the rise of the intracellular *p*H after fertilisation (Fig. 2). These eggs were seen to divide at a rate similar to control eggs in 25 mM Na^+-ASW without amiloride. At $2.5–5 \times 10^{-4}$ M, amiloride inhibited the rate of increase in internal *p*H. These eggs divided 30–60 min after division of control eggs. The delay of cleavage by amiloride between 2.5 and 5×10^{-4} M could be eliminated by washes of natural seawater 20 min after fertilisation. At 10^{-3} M, amiloride in 25 mM Na^+-ASW (glucose substitution, see Fig. 2 legend) blocked the rise of internal *p*H,

although the elevation of the fertilisation membrane was observed. The inhibition by amiloride at 1 mM was irreversible, as the internal *p*H remained acidic after the removal of amiloride by repeated washes of natural seawater (arrow, Fig. 2).

The reduction of external Na^+ to 25 mM (choline substitution) did not inhibit the alkalisation after fertilisation (Fig. 3). An intracellular *p*H increase in external Na^+ of 5 mM, which is near the minimal external Na^+ required for activation of metabolism after fertilisation[7], has been observed. The *p*H of this unfertilised egg was 6.83 and the membrane potential −18 mV. As the *p*H of the medium was 8, there is a net outward driving force on protons of 50 mV. After fertilisation, the *p*H of the egg was 7.14 and the membrane potential was −73 mV, giving an inward driving force on protons of 23 mV. This reversal of the driving force on protons with egg activation was similar to observations made in natural seawater[6]. As protons are not in electrochemical equilibrium across the egg plasma membrane, the presence of an active mechanism regulating cytoplasmic *p*H is implied. It has been reported that transfer of fertilised eggs to Na^+-free ASW 10 min after fertilisation did not inhibit development[7]. This suggested that external Na^+ was not required for the maintenance of the alkaline *p*H of fertilised eggs. As seen in Fig. 3, the removal of external Na^+ did not affect the internal *p*H. Furthermore, we exposed the eggs to a brief pulse of acidic (*p*H 6.5) Na^+-free ASW. The cytoplasmic *p*H fell rapidly and stabilised at a new value of 6.67. During the acidic pulse, the membrane depolarised to −66 mV, due to a loss of newly developed potassium conductance[15]. The inward driving force on protons had increased to 76 mV. After the bath was returned to Na^+-free ASW, *p*H 8, the cytoplasmic *p*H and membrane potential recovered. The subsequent elevation of the external Na^+ to 80 mM had little effect on either the membrane potential or intracellular *p*H. Because, in the absence of external Na^+, exposure of eggs to acidic medium caused an increase of the inward driving force on protons and the cytoplasmic *p*H recovered following the return to an alkaline medium, the active mechanism regulating the internal *p*H of fertilised eggs was not dependent on external Na^+.

These data demonstrate that external Na^+ is necessary for the rise of the internal *p*H after egg activation. However, once the rise of the internal *p*H has been completed, external Na^+ was not required for maintaining the new alkaline *p*H. As in other tissues, protons are not in electrochemical equilibrium across the cell membrane of the sea urchin egg, implying the existence of an active mechanism regulating the cytoplasmic *p*H. However, the measured net outward driving force on protons of unfertilised eggs may be a consequence of impalement. Because of the high input impedance of unfertilised sea urchin egg membrane[15,16] and the large tip diameters of the *p*H microelectrode, the low resting potential is probably due to a leakage artefact. Careful recordings of the membrane potentials of unfertilised *L. pictus* eggs with a single KCl microelectrode gave membrane potential values near −75 mV (R.A.S., S.A. McClure and S.S.S., in preparation), in close agreement with the values reported for other species of sea urchin eggs[16,17]. If the true values of the internal *p*H and membrane potential of the unfertilised egg are near 6.8 and −75 mV respectively, proton distribution across the plasma membrane would be near passive equilibrium. Alternatively, our reported values of cytoplasmic *p*H of unfertilised eggs may be a consequence impalement and may not reflect the true values. This possibility cannot be totally refuted; however, several lines of evidence suggest that the measured values are near the true values despite the lowered membrane potential. Preliminary experiments indicate that the intracellular *p*H of sea urchin eggs is insensitive to alterations of the membrane potential using voltage clamp techniques and estimation of the internal *p*H of unfertilised eggs by the distribution of labelled 5,5'-dimethyl-2,4-oxazolidinedione (DMO) gave values near 6.8 (ref. 18). This difficulty of leakage artefact is not encountered with the fertilised egg due to its lower input impedance[15,16].

The elevation of the cytoplasmic *p*H associated with activation of the egg required minimal amounts of external Na^+, however, the precise mechanism by which a small amount of sodium permits this alkalisation remains unclear. It has been proposed that the external Na^+ is necessary for a Na–H exchange[8]. Our data on the insensitivity of the alkalisation of the egg cytoplasm to reductions of external Na^+ until the critical threshold concentration and the high concentrations of amiloride necessary for inhibition weakens the Na–H exchange hypothesis. An Na–H exchange has been suggested for the regulation of intracellular *p*H of the mouse soleus muscle fibres. The recovery of the internal *p*H of the mouse soleus muscle fibres following acidification was significantly slowed by an 11% reduction of external Na^+ and blocked by amiloride at 10^{-4} M

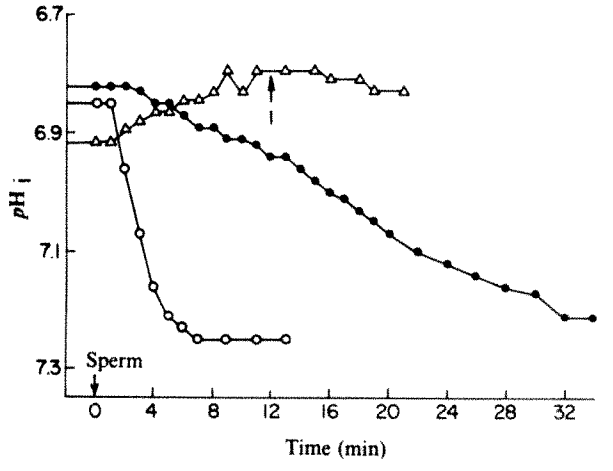

Fig. 2 The effect of amiloride on alkalisation after egg fertilisation. Amiloride at 10^{-4} M (○) had no significant inhibition, at 2.5×10^{-4} M (●) inhibited the rate of alkalisation and at 10^{-3} M (△) blocked alkalisation. Amiloride at 1 and 2.5×10^{-4} M was tested in 25 mM Na^+-ASW, *p*H 8, where choline was substituted for sodium. Amiloride at 1 mM was tested in 25 mM Na^+-ASW, *p*H 8, where glucose (739 mM) was substituted for sodium. No differences in the intracellular *p*H and membrane potentials during fertilisation of controls were observed between glucose and choline replacement for external sodium. Amiloride was obtained from Merck, Sharp & Dohme Research Laboratory and at 1 mM required extensive stirring and slight heating (35 °C), as well as the reduction of the ionic content of ASW. The inhibition by amiloride at 1 mM was not reversed after washing with SW, *p*H 8 (arrow).

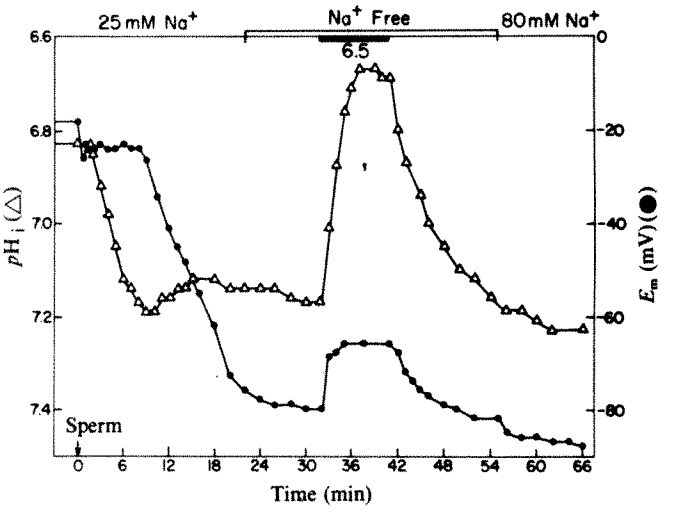

Fig. 3 The effect of external Na^+ and *p*H on the membrane potential (E_m) (●) and the intracellular *p*H (pH_i) (△) after fertilisation. The egg was fertilised in 25 mM Na^+-ASW, *p*H 8 (choline substitution). At 22 min after fertilisation, the external Na^+ was removed. Subsequently, the egg was pulsed for 9 min with Na^+-free ASW, *p*H 6.5. At 55 min, ASW was added to the bath to raise the external Na^+ to 80 mM.

(ref. 19). We have found that the alkalisation after egg activation was not inhibited by a 99% reduction of external Na^+ and inhibition by amiloride only occurred at concentrations in excess of 10^{-4} M with the external Na^+ reduced to 25 mM. It has been reported that amiloride at 2.5×10^{-4} M in 115 mM Na^+-ASW did not inhibit acid production after fertilisation of *Psammechinus miliaris* eggs. However, the rate of acid production was slowed in the presence of the drug[20]. Our data on the relationship between amiloride and external Na^+ concentrations on the alkalisation of the cytoplasm suggested that sodium and amiloride are competitive for binding sites, similar to amphibian tissues[21]. However, the inhibitory concentrations of amiloride necessary is 1,000-fold greater for eggs than epithelia. The effect of such high concentrations of amiloride on eggs may be nonspecific; that is, the effect may be on some process other than ion exchange. As less than 5 mM external Na^+ is required for the elevation of cytoplasmic *p*H associated with egg activation and external Na^+ is not required for maintaining the alkaline *p*H of fertilised eggs, we propose a possible allosteric role for sodium. The binding of sodium to sites on the plasma membrane of the fertilised egg is required for activation of the mechanism directly involved with the alkalisation of the cytoplasm.

Membrane response to 1-methyladenine requires the presence of the nucleus

B. Dale, A. de Santis & M. Hoshi

Stazione Zoologica 80121 Naples, Italy

Meiosis is re-initiated in starfish oocytes by the action of the hormone 1-methyladenine (1-MA)[1]. It is thought that the primary trigger is localised at the plasma membrane[2,3], and early changes reported are the activation of a Na^+ pump[4] and variation in membrane potential and conductance[5,6]. We report here that external application of 1-MA results in an irreversible switching of the starfish oocyte membrane from one stable electrical state to another. This induced change requires the presence of the germinal vesicle.

The resting potential of *Astropecten aurantiacus* oocytes ranges from −70 to −90 mV. Increasing $[K^+]_{out}$ by a factor of 10 results in a decrease in the resting potential of 44 mV, approximately as predicted by the Nernst equation for a K^+ selective membrane. At rest, specific membrane resistance may range from 2 to 8 kΩ cm^2 (egg diameter 300 μm). On addition of 10^{-6}M 1-MA to the bath, we observed a depolarisation of about 0.5 mV min^{-1} and a gradual increase in input resistance of 0.5 MΩ min^{-1}. At 15 to 30 min later the membrane switched to a new stable electrical state of −10 to −20 mV; 50–170 kΩ cm^2. In this state, increasing $[K^+]_{out}$ by a factor of 10 did not produce any significant change in the resting potential. Concurrent with the switch, or shortly after, the germinal vesicle was observed to break down. It has been shown elsewhere that sea urchin oocytes have resting potentials in the range −50 to −70 mV, whereas this value in mature eggs is −8 to −16 mV (refs 7, 8). The disappearance of K^+ selectivity after maturation has been reported for amphibians[9,10] and starfish[11].

Offsetting the resting potential of oocytes in the depolarising direction also causes the switch, but the germinal vesicle remains intact. In these cases the switch is reversible (by offsetting in the hyperpolarising direction, or spontaneously). In contrast 1-MA matured oocytes cannot be induced to switch back to the original high potential level. This means the two stable resting states pre-exist in the starfish oocyte, as previously hypothesised[11], and that following maturation only one stable state remains. The current–voltage relationships for the starfish oocyte before and after 1-MA treatment are shown in Fig. 1, together with the switch in potential. The voltage excursion in the absence of 1-MA was limited to prevent the switch occurring. The existence of two stable resting states in the untreated oocyte implies an N-shaped *I–V* curve, with two regions of positive slope conductance connected by a third region of negative slope conductance[11]. Such a curve may only be measured in its entirety in voltage clamp conditions.

We suggest that 1-MA interacts with externally situated plasma membrane structures. This would (1) directly cause the progressive closure of K^+ channels, or (2) cause a leak across the membrane which subsequently depolarises the membrane so closing K^+ channels. In fact, the shape of the curve of the *I–V* relationship for the untreated oocyte (Fig. 1) implies that K^+ channels may be closing due to depolarisation. When the conductance approaches zero the membrane becomes unstable and switches to the low potential state. This resting potential level may be regulated by a different population of ionic channels, which are probably nonspecific. Although the switch can occur either by current injection or by interaction with the hormone, the germinal vesicle only breaks down in the latter

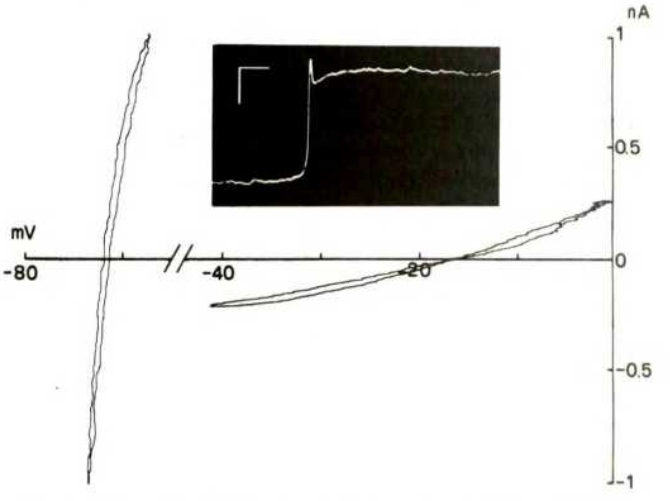

Fig. 1 Recordings from oocytes, complete with jelly and follicle cells, in natural seawater at 20 °C. The inset shows a 1-MA induced switch in an oocyte with an initial resting potential of −80 mV. Horizontal bar represents 5 s, vertical bar 10 mV. The *I–V* curves were obtained by injecting current (*I*), with a sine wave generator (<0.02 Hz), through one intracellular electrode and recording voltage (*V*) with a second intracellular electrode. The curve on the left is from an oocyte before 1-MA treatment, that on the right from the same oocyte after the switch.

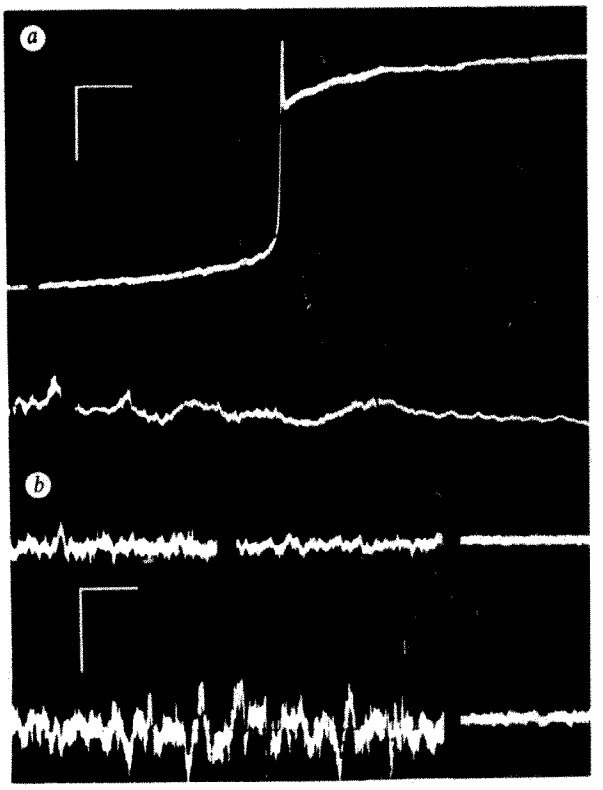

Fig. 2 Anucleated and nucleated fragments were obtained by centrifugation of oocytes in a sucrose gradient at 12,000 r.p.m. or by hand dissection. In each experiment a nucleated and an anucleated fragment of similar size (100–150 μm) were impaled. 1-MA was added to the bath and the responses of both fragments were monitored simultaneously. *a*, The upper trace is from a nucleated fragment which had an original resting potential of −85 mV, and the lower trace is from an anucleated fragment with a resting potential of −95 mV. The horizontal bar represents 5 s, the vertical bar 10 mV. *b*, Voltage noise, a.c. coupled from 1 Hz, in a nucleated fragment (upper) and an anucleated fragment (lower). Upper traces show, from left to right, the spontaneous voltage noise before the switch, after the switch and the microelectrode noise after pulling out the oocyte. Lower traces show, on the left the voltage noise from an anucleated fragment and on the right microelectrode noise after the experiment. The horizontal bar represents 1 s, the vertical bar 0.5 mV.

case. This raises the possibility of the involvement of a secondary factor in the maturation of oocytes.

Starfish oocytes can be divided into nucleate and anucleate halves either manually or by centrifugation. As it is difficult to impale these fragments with a second microelectrode we were unable to study their *I–V* relationships. However, we were able to monitor their responses to 1-MA. Nucleated fragments behaved as intact oocytes. They had stable resting potentials in the range −70 to −90 mV, and 15 to 30 min after 1-MA addition, the switch occurred and the germinal vesicle broke down (seven fragments, upper trace in Fig. 2*a*). The switch also occurred in these fragments by offsetting the resting potential with the recording electrode. The upper traces in Fig. 2*b* show the voltage noise in a nucleated fragment before and after the 1-MA induced switch. Although in this report we have not analysed voltage noise, this characteristic change following the switch seems to be similar in intact oocytes and nucleated fragments. This difference in voltage noise together with the change in specific membrane resistance (observed in intact oocytes) implies a changed population of functional ionic channels and is consistent with our hypothesis.

Anucleated fragments had resting potentials in the range −20 to −100 mV (seven fragments). In addition these fragments, particularly those with high resting potentials, exhibited large slow fluctuations (lower trace, Fig. 2*a*). Addition of 10^{-6}M 1-MA did not induce the switch in anucleated halves, even after exposure for 60 min, and in fact offsetting the resting potential with the recording electrode resulted in a linear relationship between injected current and recorded voltage. Anucleated halves with resting potentials in the range −70 to −90 mV had significantly larger peak-to-peak voltage noise than nucleated fragments (Fig. 2*b*). This could be explained by a difference in input resistance; however, nucleated and anucleated fragments selected for recording were approximately the same size (100–150 μm) and of course the two plasma membranes have a common origin.

At present we have no explanation for the large range in resting potential of the anucleated fragments; however, those with lower resting potentials cannot be described as K^+ selective membranes, whilst those with higher potentials were insensitive to changes in $[K^+]_{out}$.

It has been suggested[2,3] that the primary trigger for 1-MA meiosis re-initiation is localised at the plasma membrane. We have shown that although the initial response is at the plasma membrane, the nucleus must be present for this response to occur. It is possible that a secondary factor controlled by, or contained in, the nucleus might be involved in this hormone induced membrane response. However, the recordings from anucleated fragments suggest that removal of the nucleus, in itself, alters the electrical properties of the membrane precluding the 1-MA membrane response.

Gonadotropin-releasing hormone analogue binds to luteal cells and inhibits progesterone production

Richard N. Clayton, James P. Harwood & Kevin J. Catt

Endocrinology and Reproduction Research Branch,
National Institute of Child Health and Human Development,
National Institutes of Health, Bethesda, Maryland 20205

Although gonadotropin-releasing hormone (GnRH) is believed to mediate the hypothalamic control of pituitary gonadotropin secretion, continuous or repeated administration of GnRH or its agonist analogues has been shown to cause paradoxical antifertility effects in several species, including primates[1–8]. GnRH-induced interruption of reproductive cycles and pregnancy is associated with diminished progesterone production, implying defective function of the corpus luteum[1,3–6]. These luteolytic effects have been attributed[4,5] to the well recognised desensitising actions of elevated luteinising hormone (LH) levels on ovarian LH receptors and steroidogenesis[9,10], subsequent to GnRH-induced gonadotropin release from the anterior pituitary. However, treatment with high doses of exogenous LH did not cause suppression of serum progesterone levels during early pregnancy in rats[8], whereas a highly active GnRH analogue was effective in this regard. These observations suggested that GnRH and its agonist analogues, given in high or sustained doses, can exert a direct action on the ovary that is independent

0028–0836/79/440090—03$01.00

of the pituitary. This hypothesis was further supported by the ability of GnRH and its agonists to inhibit human chorionic gonadotropin (HCG)-induced ovarian and uterine weight gain in hypophysectomised rats[11] and to delay the onset of puberty in intact female rats[12]. Also, GnRH and its agonist analogues have recently been shown to inhibit steroidogenesis induced by follicle-stimulating hormone (FSH) in cultured granulosa cells, confirming the direct action of such peptides on the ovarian follicle[13]. The marked inhibitory effects of GnRH and its agonists on corpus luteum function suggest that these compounds could exert direct actions by binding to specific receptors on luteal cells. The present experiments, which examine the effects of GnRH agonists on luteal steroidogenesis, demonstrate the existence of such actions and their mediation by specific high-affinity receptor sites present in luteal cell membranes.

Binding studies with the radioactive GnRH analogue ^{125}I-[D-Ser(tBu)^6]des-Gly^{10}-GnRH *N*-ethylamide (GnRH-A) demonstrated specific uptake of the tracer peptide in both dispersed luteal cells and membrane-rich particles from the luteinised rat ovary. The specific binding of GnRH-A to isolated luteal cells was rapid and saturable, and Scatchard analysis (Fig. 1) indicated that the labelled analogue was bound by a single class of high-affinity receptors ($K_a = 4.4 \times 10^9\ M^{-1}$) presumably located in the plasma membrane. A particulate membrane-rich fraction from ovarian homogenates also bound the labelled analogue, with a comparably high affinity of $5.8 \times 10^9\ M^{-1}$. Binding of the labelled analogue was completely inhibited by 10^{-7} M native GnRH. The binding–inhibition curve obtained with unlabelled GnRH was parallel to that derived with the unlabelled analogue, although for any given displacement a

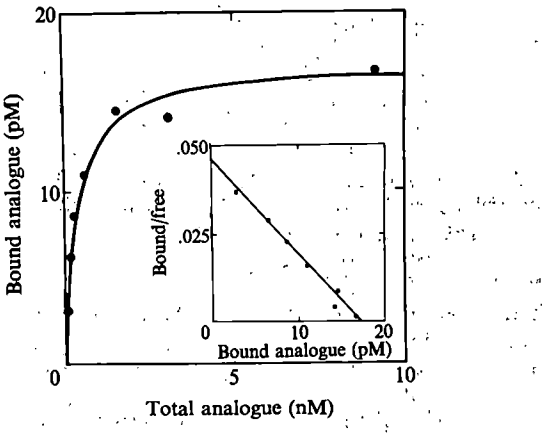

Fig. 1 Binding of ^{125}I-labelled GnRH-A to collagenase-dispersed luteal cells prepared from ovaries of 25-d-old female rats treated with 50 IU PMSG and 25 IU HCG to induce ovarian luteinisation[9]. Animals were killed 8 days after PMSG treatment and isolated cells prepared from the minced ovaries by incubation with 2 mg ml^{-1} of collagenase (Worthington, Type 1 140 U mg^{-1}) in medium 199 containing 0.2% bovine serum albumin (BSA). After 10 min, the collagenase-treated fragments were dispersed by repeated aspiration and filtered through nylon mesh. The resulting cell suspension was preincubated in medium 199/0.2% BSA for 90 min at 36 °C, then centrifuged at 1,500*g* for 10 min. The cell pellet was resuspended in assay buffer (medium 199/0.1% BSA/25 mM HEPES/0.5 mM bacitracin), and triplicate aliquots of 2×10^6 cells were incubated with 3×10^{-11} M ^{125}I-[D-Ser(tBu)^6]des-Gly^{10}-GnRH *N*-ethylamide (1,000 μCi per μg)[15] and increasing concentrations of unlabelled analogue. Incubations were for 80 min at 22 °C in a total volume of 300 μl, and were terminated by dilution with 4 ml of ice-cold phosphate-buffered saline (*p*H 7.4). The cells were immediately separated by filtration through glass fibre filters (Whatman GF/C) and bound radioactivity was determined by γ spectrometry with a counting efficiency of 60% for ^{125}I. Nonspecific binding, assessed in the presense of 3×10^{-7} M unlabelled GnRH-A, was subtracted from all datum points. The total binding when 50,000 c.p.m. of tracer GnRH-A was added was 4–6%, of which 1/5th represented nonspecific binding. The graph depicts a saturation curve and a Scatchard plot (inset) of the data from a representative experiment. Each point is the mean of triplicate determinations which agreed within 10%. The binding affinity, determined from four experiments by computerised Scatchard analysis[14] was $4.4 \pm 0.75 \times 10^9\ M^{-1}$, and the binding capacity was 1.5×10^{-11} M (equivalent to 2,000 sites per cell assuming 75% of cells to be luteal cells).

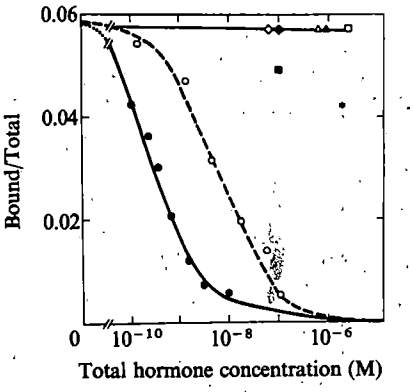

Fig. 2 Specificity of GnRH analogue binding to the 10,000*g* particulate fraction prepared from PMSG/HCG-primed ovaries as previously described for pituitary tissue[14]. The ^{125}I-labelled GnRH analogue (3×10^{-11} M) was incubated with ovarian particles equivalent to 180 μg of membrane protein, with increasing concentrations of unlabelled GnRH-A (●) or native GnRH (○). Incubations were carried out in ice for 80 min in 0.5 ml of assay buffer (10 mM Tris/HCl, *p*H 7.6, containing 1 mM dithiothreitol and 0.1% BSA). Termination of the incubations and separation of the bound fractions were as described for Fig. 1. The equilibrium association constants (K_a) for the GnRH analogue and native GnRH were $5.8 \pm 1.0 \times 10^9\ M^{-1}$ ($n = 3$) and $2.5 \times 10^8\ M^{-1}$, respectively. The binding capacity (receptor concentration) for GnRH-A was 51 ± 12 fmol per mg of ovarian membrane protein. Angiotensin I (▲), angiotensin II (△), thyrotropin-releasing hormone (□), somatostatin (*), ovine LH (◆), ovine prolactin (◇) and HCG (■) (CR 119) were diluted in assay buffer and added at the final concentrations shown.

10-fold higher concentration of GnRH was required (Fig. 2). Thus, native GnRH binds to the same sites as the analogue, albeit with significantly lower affinity ($K_a = 2.5 \times 10^8\ M^{-1}$). Particulate fractions prepared from immature rat ovaries 3 days after priming with pregnant mare serum gonadotropin (PMSG) alone, before the extensive luteinisation induced by HCG treatment, also bound the GnRH analogue with high affinity ($K_a = 9.7 \times 10^9\ M^{-1}$).

The specificity of binding of the labelled GnRH analogue by ovarian receptor sites was examined by competition studies with a series of peptides, as shown in Fig. 2. Angiotensin I, angiotensin II, thyrotropin-releasing hormone and gonadotropic hormones did not inhibit binding of the analogue to ovarian receptors. Only one peptide tested, somatostatin, was slightly inhibitory at high concentrations (10^{-6} M). The tissue specificity of GnRH binding was indicated by the absence of analogue uptake in similar fractions prepared from liver, kidney, adrenal cortex, hypothalamus and cerebral cortex.

To determine the biological function of the ovarian GnRH receptors, the action of the GnRH analogue on progesterone production was examined in isolated luteal cells. In the presence of 5×10^{-7} M GnRH-A, basal progesterone production was reduced by 25% and the stimulating effect of low concentrations of HCG ($< 10^{-13}$ M) was completely inhibited (Fig. 3). In the presence of the GnRH analogue, the maximum progesterone production in response to HCG was similar to that observed in control cells, although a much higher concentration of HCG was required to evoke the maximum steroid response. The ED_{50} for HCG stimulation of progesterone production was increased 25-fold, from 2.5×10^{-13} to 6.0×10^{-12} M, in cells incubated with 5×10^{-7} M GnRH-A. Inhibitory effects of the GnRH analogue, as well as natural-sequence GnRH, were observed at concentrations as low as 10^{-9} M. The inhibitory effect of GnRH peptides on gonadotropin-induced steroidogenesis was not due to interference with hormone binding, as high concentrations of the analogue (up to 10^{-5} M) had no effect on specific uptake of ^{125}I-HCG and ^{125}I-labelled human FSH by ovarian homogenates.

These studies have demonstrated the presence of specific receptor sites for GnRH and an agonist analogue in both isolated luteal cells and particulate membrane-rich fractions prepared from luteinised ovaries. The affinities of the ovarian

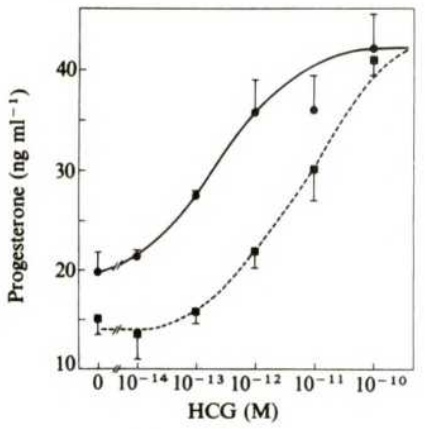

Fig. 3 Effect of [D-Ser(tBu)^6]des-Gly^{10}-GnRH *N*-ethylamide on HCG-induced progesterone production by isolated luteal cells. The cells were prepared as described in Fig. 1 legend, and 2-ml aliquots of cell suspension (2×10^6 cells ml^{-1}) were added to plastic vials containing appropriate dilutions of the hormones. After incubation for 3 h at 36 °C, the suspensions were transferred to glass tubes, centrifuged at 3,000*g* for 10 min, and the supernatant analysed for progesterone by radioimmunoassay[16]. Each point represents the mean ±s.e.m. of values from triplicate incubations. ●, −GnRH-A; ■, +GnRH-A (5×10^{-7} M).

receptors for both GnRH and the highly active analogue were similar to those of the pituitary GnRH receptors for these peptides[14]. However, the GnRH receptor concentration in the ovary was only 20% of that in the pituitary (50 and 235 fmol per mg protein, respectively). Inhibition of progesterone production in isolated luteal cells was observed with low concentrations of both GnRH and its active analogue, consistent with the high binding affinity of the luteal cell receptors. These results suggest that ovarian GnRH receptors mediate the extra-pituitary action of exogenous GnRH and its agonist analogues on progesterone production by the corpus luteum. In addition to their presence in luteinised ovaries, the demonstration of GnRH receptors in ovaries of PMSG-treated rats suggests that such sites mediate the recently reported inhibitory effect of GnRH on FSH-stimulated oestrogen production by granulosa cells[13].

The present observations in ovarian luteal cells, together with those of Hsueh and Erickson[13] in granulosa cells, provide an explanation for the paradoxical effects of GnRH and related compounds on reproductive processes in the female. It is clear that the actions of GnRH agonists are mediated through specific receptors that are separate from the gonadotropin receptors in the ovary, and that such sites are present in both granulosa and luteal cells. The inhibitory effects of GnRH and its analogues cannot be ascribed to interference with gonadotropin binding, thus implying that GnRH and its agonists act at a stage after gonadotropic hormone–receptor interaction. In the present study, the major effect of the analogue was to reduce target-cell sensitivity to gonadotropin, causing a shift in the dose–response curve, with no change in the maximum progesterone production evoked by high concentrations of chorionic gonadotropin. These results indicate that the GnRH analogue acts as a competitive inhibitor of gonadotropin-stimulated progesterone production, at least in short-term studies.

Anti-fertility effects of GnRH and its analogues have been previously observed *in vivo* after pharmacological doses of these peptides. Our findings have demonstrated that receptor-mediated inhibitory actions of GnRH and an active analogue are detectable *in vitro* at low concentrations of the peptides. Because GnRH is undetectable in the systemic circulation, it is unlikely that GnRH of hypothalamic origin could reach the ovary in sufficient concentration to exert a direct action on the corpus luteum. It is conceivable that GnRH or a related peptide is produced in the uterus and transported to the ovary, or is formed locally in the ovary where it acts as a mediator of normal luteolysis. This mechanism, and the possibility that GnRH binds to a heterologous receptor in the ovary in a manner analogous to the morphine/enkephalin interaction, raise intriguing questions about the biological significance of the extra-pituitary actions of GnRH and its analogues.

Ovarian ecdysone secretion is controlled by a brain hormone in an adult mosquito

H. H. Hagedorn, J. P. Shapiro & K. Hanaoka

Department of Entomology, Cornell University, Ithaca, New York 14853

In the mosquito *Aedes aegypti*, a blood meal triggers egg development. Early workers used the simple technique of decapitation, or neck ligation, to show that a factor from the head was required for normal egg development[1–4]. Lea subsequently demonstrated that the source of this factor was the medial neurosecretory cells of the brain[5]. The hormone from these cells, which he termed the egg development neurosecretory hormone (EDNH), is stored in the corpus cardiacum (CC) and released shortly after a blood meal[6]. Previous work had demonstrated that the ovary begins to produce ecdysone after a blood meal[8]. Considerable evidence suggests that the ecdysone, after being converted to 20-hydroxyecdysone, stimulates the synthesis and secretion of vitellogenin by the fat body[8–12]. The vitellogenin is taken up by the growing oocytes and becomes part of the yolk. Analysis of the amount of 20-hydroxyecdysone present in females after a blood meal showed that significant quantities were first seen 4–6 h after a blood meal[8]. Vitellogenin synthesis begins at about the same time[13]. The early decapitation experiments of Gillett demonstrated that the head was necessary for 4–8 h after a blood meal for egg development to proceed normally[3]. A similar critical time was found for the control of vitellogenin synthesis by the brain hormone[7]. The coincidence of this timing suggested to us that the ovary was the target of the brain hormone. The experiments reported here were designed to test the hypothesis that the brain hormone released after a blood meal acted on the ovary, causing the synthesis of ecdysone. Our results confirm this.

In earlier work we had successfully stimulated vitellogenin synthesis by incubating ecdysone-secreting ovaries with fat body preparations[7]. Our success with this *in vitro* approach prompted us to try to activate ovarian secretion of ecdysone by incubating ovaries with brains. Ecdysone in the medium after incubation was measured using an ecdysone radioimmunoassay[14]. We found that incubating whole brains (not including the CC, as it is removed with the aorta) with ovaries stimulates ecdysone secretion (Table 1). This effect is almost entirely due to the

Larval brain and CC	163±28
Adult brain and CC	149±17
Musca domestica (fly)	
Adult brain	132±18

Parts of the nervous system from five animals were frozen and thawed and incubated with ovaries from 10 female mosquitoes for 18 h at 25 °C in sterile *Aedes* saline[18] containing 0.15 mg ml^{-1} penicillin and 0.25 mg ml^{-1} streptomycin. This saline is isosmotic with haemolymph[19]. The adults used were 3–5 d old and were maintained on 3% sucrose at 27 °C. The medium and one rinse of the ovaries were combined and assayed for ecdysone using a radioimmunoassay (RIA)[14]. As we have previously shown that ovaries secrete only α-ecdysone when incubated *in vitro*[8], the results are expressed as pg ecdysone per 10 pairs of ovaries. The antiserum used was approximately equally sensitive to α-ecdysone and 20-hydroxyecdysone. Ovaries without any added nervous system gave a background of 40 pg of ecdysone that was subtracted from the above values in this experiment only. Each value represents the mean ± s.e.m. of three replicate studies. No correction is made in these data for the relative size of the brains used.

midbrain; other parts of the nervous system have little or no effect. Brains from adult males and from larvae also stimulate ovaries, although larval brains have half the activity of adult brains. Surprisingly, the CC and/or brains of several related insects activate ecdysone synthesis by mosquito ovaries (Table 1). The CC of larval cockroaches show considerably greater activity than those of adults. Cockroach CC is also much more active than brains and CC from a butterfly or the brains of a fly. The control of ovarian ecdysone secretion by a brain hormone in *Locusta* has been recently described[15] but in this case male or larval brain and CC were not stimulatory.

Saline extracts of whole mosquito heads also stimulate ecdysone production by the ovary. Ecdysone synthesis is linear for 10 h after exposure to head extracts, with a lag of 0.5 h (Fig. 1). In contrast, there is a delay of 6–8 h after a blood meal before the main peak of ecdysone is seen in the whole animal[8]. As the response *in vitro* is almost immediate (Fig. 1), this suggests that release of brain hormone *in vivo* is delayed. Gillett[3] came to the same conclusion by noting the effects of decapitation on egg development. The incubated ovaries are quite sensitive to the factor in head extracts: the amount of hormone present in 1.5–2 heads is sufficient to stimulate a half-maximal response in 10 pairs of ovaries incubated in 50 μl of extract (Fig. 2). At high concentrations of head extract the stimulation of ecdysone is inhibited. This effect has been noted repeatedly and is apparently due to a detrimental factor in the extract that is diluted out more rapidly than the hormone. Heating the extract has no effect on the inhibition.

Evidence that the ovary produces ecdysone *de novo* in response to the brain hormone was obtained by examining the amount of ecdysone in the ovaries and incubation medium before and after exposure to head extract (Table 2). A small amount of ecdysone is detectable in the ovary before the

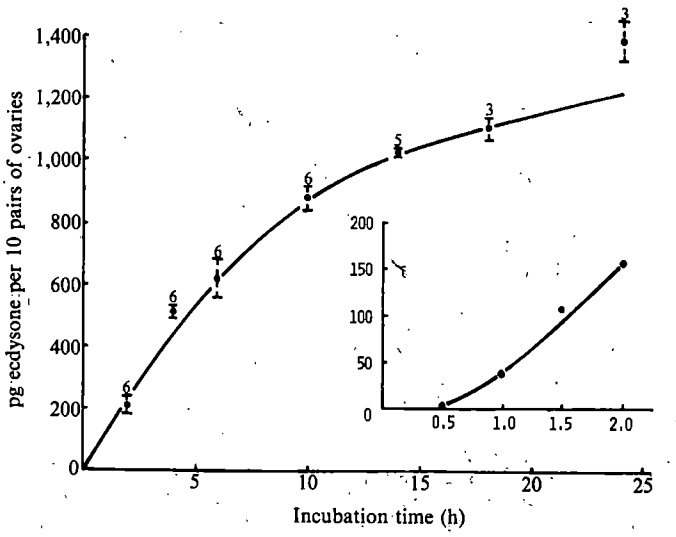

Fig. 1 Time course of ecdysone synthesis in response to head extract. 10 mg of heads were homogenised in 1 ml of sterile *Aedes* saline and treated as described in Table 2 legend except that the extract was not heated. The medium was assayed for ecdysone by RIA[14] after incubation. The data points represent the mean ± s.e.m. The number of replicates is indicated. The inset represents a separate experiment with two replicates, each with 20 pairs of ovaries. Ovary donors were as described in Table 1.

experiment. After 18 h with the head extract, 30 times more ecdysone is found in the incubation medium than in the ovary.

We have demonstrated that the ovary is indeed the target tissue of a brain hormone that stimulates ecdysone synthesis. This hormone is probably identical with the EDNH described by Lea[5,6], as the active factor is found in the region of the brain containing the medial neurosecretory cells (Table 1). A major unsolved problem concerns the nature of the stimuli that cause the release of EDNH after a blood meal. Neither the act of feeding nor stretching of the abdomen during feeding seems to be important[6]. There is some evidence that a humoral agent released after blood feeding is involved; this may be an early product of blood meal digestion[16].

EDNH is analogous in function to PTTH, the prothoracicotropic hormone found in immature insects. Both cause the synthesis of ecdysone by their respective target tissues; the function of the ecdysone in immature insects is to cause moulting. The similarity may be more than analogous, given that

Table 2 Synthesis of ecdysone by ovaries in response to head extract

Heads were obtained from 5–10-d old adult mosquitoes maintained on 3% sucrose by shaking animals frozen at −60 °C to break them apart and separating out the heads using US standard sieves. Heads were retained by a mesh size of 0.425 mm, lyophilised and 5 mg (36 μg per head) homogenised in 1 ml of sterile *Aedes* saline[18]. The extract was then sonified three times for 0.5 min and centrifuged for 5 min at 9,000*g*. The extract was heated at 50 °C for 15 min and centrifuged again. Heating effects some purification but does not significantly reduce the activity of the extract. Samples of supernatant (50 μl) were incubated with 3 groups of 10 pairs of ovaries each. After 18 h the ovaries were removed and combined to provide enough material for the RIA. Also 30 pairs of ovaries that were not incubated were dissected. The ovaries were homogenised and extracted with 50% methanol. The supernatant after centrifugation for 5 min at 9,000*g* was dried down and assayed for ecdysone by RIA[14]. The saline extract before and after incubation was also analysed for ecdysone. Ovary donors were as described in Table 1.

Nature Vol. 282 1 November 1979

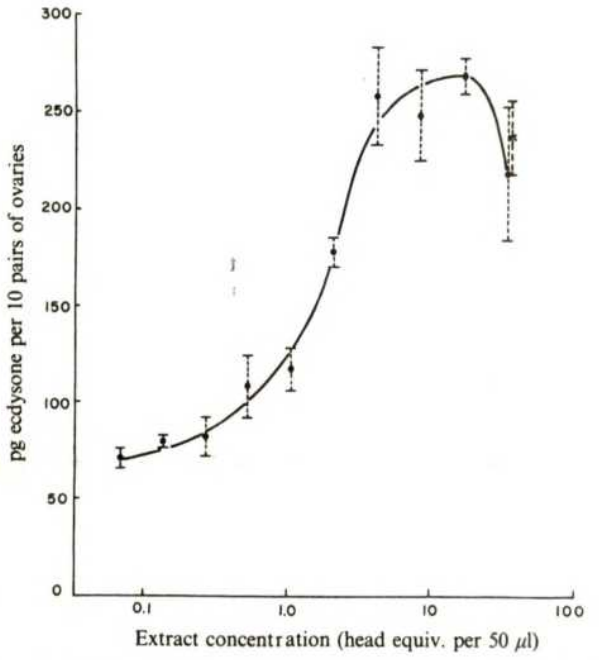

Fig. 2 Ecdysone synthesis by ovaries in response to increasing amounts of head extract. 20 mg of mosquito heads obtained as described in Table 2 legend were homogenised in 0.8 ml of sterile saline[18]. The extract was frozen and thawed and then centrifuged for 30 min at 10,000*g*. The sample was divided, one part was serially diluted and the other heated at 50 °C for 15 min. Ovaries from 10 7-d-old females were incubated with 50-μl samples of the extract for 6 h at 25 °C. Ecdysone was determined in the incubation medium by RIA[14]. The results were converted to head equivalents by the factor, 1 head = 36 μg. Data given are mean ± s.e.m. of five replicates. X Indicates the heat-treated sample.

EDNH activity is present in larval mosquito brains and the brains and CC of several other insects. It is possible that these two hormones are structurally similar and therefore homologous to some degree. Work in our laboratory on the chemistry of EDNH has shown it to be a peptide of molecular weight about 6,500 with some similarities to PTTH from *Bombyx mori*[17].

The neuroendocrine control of ecdysone synthesis by the mosquito ovary resembles in several ways the control of oestrogen synthesis by the vertebrate ovary. In both, a peptide produced by neurosecretory cells or the pituitary stimulates the synthesis of a steroid by the ovary. Perhaps the cyclic production of eggs that occurs in both is best accomplished by this type of control mechanism.

We thank Dr J. D. O'Connor for the antisera used for the ecdysone radioimmunoassay, G. Wheelock for technical assistance, Dr Paul Feeny for supplying the butterflies and Dr David Pimentel for the houseflies. This work was supported by grant no. AI 14771 from NIH and by Cornell Agricultural Experiment Station project no. 420.

A circadian oscillator in cultured cells of chicken pineal gland

Takeo Deguchi

Department of Medical Chemistry,
Tokyo Metropolitan Institute for Neurosciences,
2–6 Musashidai, Fuchu-city, Tokyo 183 Japan

The activity of serotonin *N*-acetyltransferase, the key enzyme of melatonin synthesis, shows a marked circadian rhythm in the pineal glands of various animal species[1–10]. The regulation mechanism of the *N*-acetyltransferse rhythm in birds is different from that in mammals. *N*-Acetyltransferase activity in rat pineal gland is controlled by the central nervous system through the sympathetic nerves from the superior cervical ganglion[1–6], while in chicken the endogenous oscillator for *N*-acetyltransferase rhythm is presumably located in the pineal gland. Recently it has been shown that *N*-acetyltransferase activity oscillates in a circadian manner in the organ culture of chicken pineal glands[11–13]. When chicken pineal glands were organ-cultured under continuous illumination, the nocturnal increase of enzyme activity was suppressed. These observations suggested that chicken pineal gland contains a circadian oscillator, a photoreceptor and melatonin-synthesising machinery. A central question arises whether the circadian oscillation of *N*-acetyltransferase activity and its response to environmental lighting are generated within the cell or are emergent properties of interaction between different types of pineal cells. I report here that in the dispersed cell culture of chicken pineal gland, *N*-acetyltransferase activity exhibits a circadian rhythm and responds to enviromental lighting in the same manner as in the organ culture.

Chickens (White Leghorn cockerels) were raised under the lighting schedule with lights on from 7 a.m. to 7 p.m. for 12–14 days after hatching. After decapitation, their pineal glands were dissociated by treatment with collagenase. More than 90% of the cells were viable as judged by Trypan blue exclusion. Shortly after the treatment with collagenase, most of the cells were dispersed and there was little cell–cell attachment. The typical morphological appearances of the cultured cells are shown in Fig. 1. After inoculation in dishes, some of the cells tended to reaggregate into small clusters. Within 24 h fibroblasts had developed processes. Round cells were alive and mostly attached to fibroblasts, although some remained isolated.

When dispersed cells were cultured in a light–dark cycle (LD 12 : 12), both the specific activity (per mg protein) and the total activity (per dish) of *N*-acetyltransferase were 5–10-fold higher during the dark periods than in the light periods on days 2 and 3 of culture (Fig. 2*a*, *b*). As the protein content increased, with doubling time of about 1.5 days, the total enzyme activity showed a more marked difference between day and night-time.

Table 1 Effect of conditioned medium on *N*-acetyltransferase activity in cell cultures

Medium added	*N*-acetyltransferase pmol per mg protein per 10 min
Medium unchanged	313 ± 17
Daytime conditioned medium	344 ± 41
Night conditioned medium	361 ± 22

Conditioned medium was taken from the 3-day cell culture during daytime (3 p.m.) or at night (3 a.m.) in darkness, and was added to other 3-day cell cultures next day at 11 a.m.. The incubations were continued until 5 p.m. and *N*-acetyltransferase activity was measured. The results are means ± s.e.m. of five samples.

© 1979 Macmillan Journals Ltd

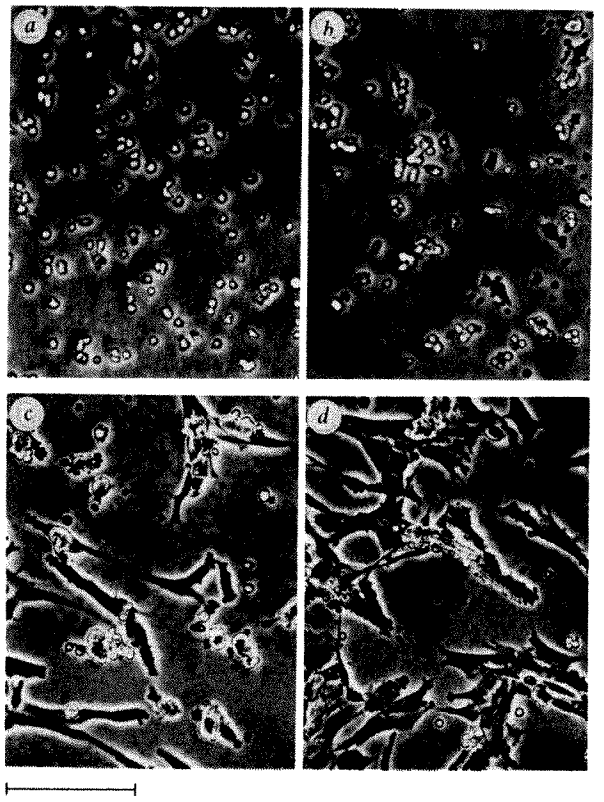

Fig. 1 Phase contrast micrographs of dispersed pineal cells shortly after inoculation (*a*), after 24 h (*b*), 48 h (*c*), and 60 h (*d*) of culture. Scale bar, 100 μm. Eighty to ninety chickens were killed between 2 and 3 p.m. by decapitation. The pineal glands were freed of connective tissues and severed into small pieces by pincettes under a stereo microscope. The pineal tissues were incubated in a 40-ml tube containing 25 ml of incubation mixture at 37 °C with constant shaking. The incubation mixture consisted of 25 mM HEPES–NaOH (*p*H 7.2), 137 mM NaCl, 5 mM KCl, 0.7 mM Na_2HPO_4, 10 mM glucose, 0.36 mM $CaCl_2$, streptomycin (100 μg ml^{-1}), penicillin (100 U ml^{-1}), 1% bovine serum albumin, and 0.4% collagenase (type I) from *Clostridium histolyticum* (Sigma). During the incubation of 15–20 min, the pineal pieces were triturated by splashing the suspension against the tube wall through a thin Pasteur pipette. Undispersed fragments of the tissues were sedimented by standing the suspension for 10–15 min. The cell suspension was transferred into another tube and the cells were collected by centrifugation at 1,000*g* for 5 min. The cells were washed with 30 ml of culture medium 3 times followed by centrifugation. Suspension (4 ml) containing $1.4–1.6 \times 10^6$ cells was inoculated in a Falcon plastic culture dish (5 cm diameter). Culture medium was the same as that used for organ cultures[11]. Monolayer cultures were carried out at 40 °C in a humidified atmosphere of 10% CO_2 and 90% air in a transparent incubator box placed in a CO_2 incubator. Inside of the incubator was kept dark. When indicated, a flourescent lamp (30 W) and electric bulb (100 W) provided light through a glass door of the incubator. Intensity of the illumination was 800–1,100 lux at dish level. The culture medium was changed every 3 days.

After 3 days of culture, fibroblasts covered most of the surface of dishes, and the specific enzyme activity per mg protein decreased, although the total enzyme activity per dish was maintained for another several days (data not shown).

To examine whether the rhythmic change of *N*-acetyltransferase activity was due to a synchronised cell cycle, cytosine-1-β-D-arabinofuranoside (1×10^{-5} M) was added to the medium on day 3 of culture to inhibit cell division (Fig. 3*b*). The activity of *N*-acetyltransferase still showed a 10-fold increase at night compared to the daytime value. In another experiment, cells were cultured for 14 days (17 days after the start of culture) in the presence of cytosine-1-β-D-arabinofuranoside. *N*-Acetyltransferase activity continued to oscillate rhythmically (on day 17 of culture, daytime values at 4 p.m., 304 ± 15; night values at 4 a.m., 2,733 ± 160 pmol per mg protein per 10 min).

Dispersed cells were cultured under the LD cycle for 2 days and on the third day the lights were turned off at 1 p.m., 6 hours before the onset of usual darkness (Fig. 3*c*). *N*-Acetyltransferase activity did not increase during the subjective daytime, but increased at 10 p.m., reaching a maximum at midnight. In the experiment shown in Fig. 3*d*, cells were cultured in continuous darkness from the second day for two successive days. There were rhythmic changes of two cycles with a higher enzyme activity during the subjective night-time compared to that of the subjective daytime. However, the day–night difference was damped out on the third day of culture: the daytime levels being higher and the night-time values being lower than those of the cells cultured in the LD cycle (Fig. 3*a*).

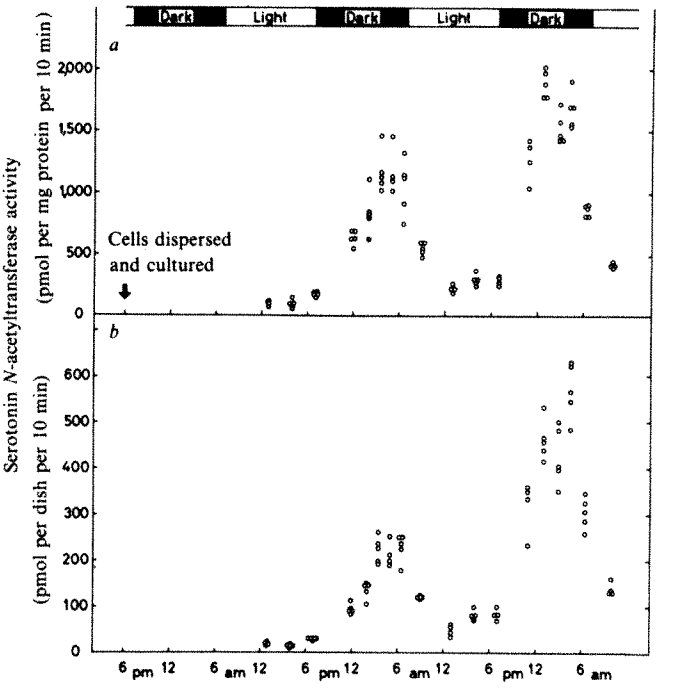

Fig. 2 *N*-Acetyltransferase activity in the dispersed cells cultured in a light-dark cycle. Cultured cells were scraped with a rubber policemen, transferred in a centrifuge tube together with the culture medium, and collected by centrifugation at 1000*g* for 10 min. The pellet was homogenised in 65 μl of 0.05 M potassium phosphate buffer (*p*H 6.5) by use of a small glass homogeniser. The homogenate (50 μl) was used for the assay of *N*-acetyltransferase activity[11] and the rest (15 μl) for the determination of protein by the method of Lowry *et al.*[17]. *a*, Specific enzyme activity (pmol per mg protein per 10 min); *b*, total enzyme activity (pmol per dish per 10 min). Each point represents the enzyme activity of individual dish.

When cells were exposed to continuous illumination in the third night, the increase of enzyme activity was suppressed to half or less (Fig. 3*e*). However, there was threefold elevation of *N*-acetyltransferase activity during the subjective night-time compared to the daytime level. These observations indicate that the rhythmic change of *N*-acetyltransferase activity in the dispersed cells is not a reaction to the environmental lighting, but is generated by an endogenous oscillator in the cells. Cells were cultured for 3 days in the LD cycle inverted to the lighting schedule in which the chickens had been raised. The rhythmic change of *N*-acetyltransferase activity was entrained to the reversed lighting schedule in which the cells were cultured (Fig. 3*f*).

To determine whether one type of pineal cell released a transmitter or a hormone which stimulated the synthesis of

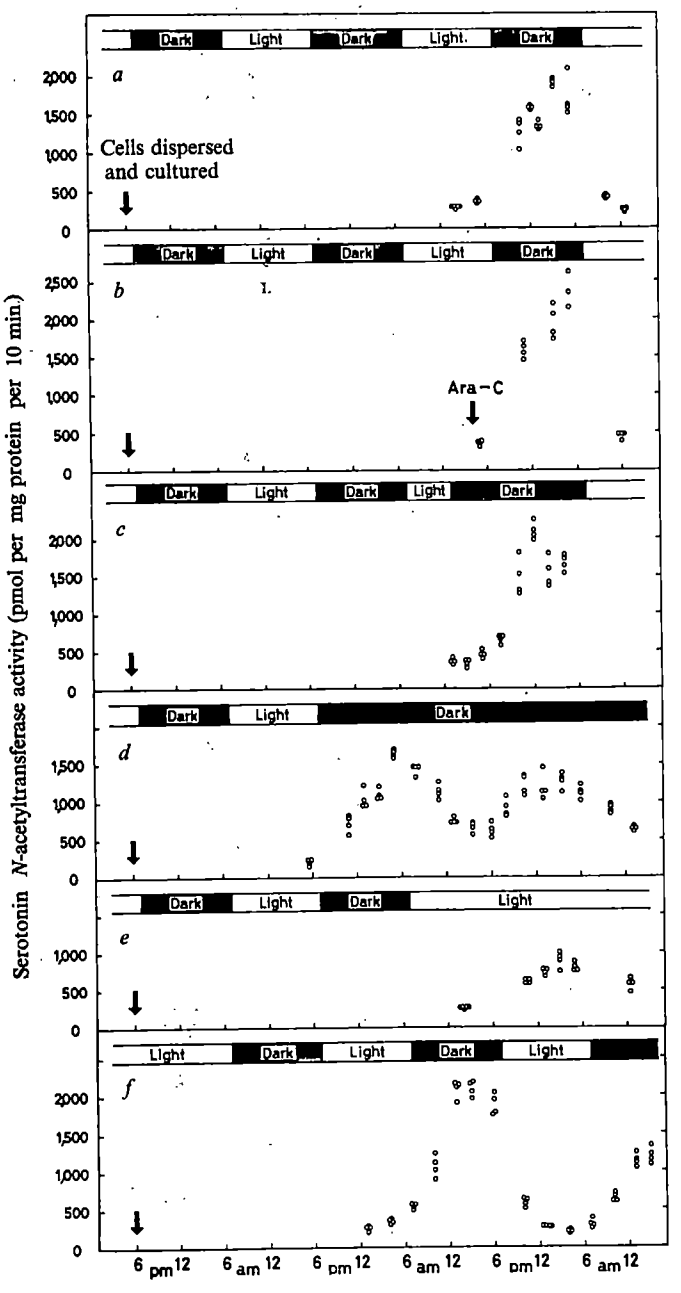

Fig. 3 *N*-Acetyltransferase activity in the pineal cells cultured under various lighting schedules. Each point represents the specific enzyme activity of an individual dish. 'Ara-C' indicates the addition of cytosine-1-β-D-arabinofuranoside (1×10^{-5} M) to the medium.

N-acetyltransferase in another type of pineal cell, conditioned medium was taken from the 3-day cell culture during daytime and at night in darkness, and was added to another cell culture at 11 a.m. when *N*-acetyltransferase activity was low. There was no significant elevation of *N*-acetyltransferase activity in both conditioned mediums (Table 1).

The present observations with the dispersed cell culture are remarkably comparable to those reported using organ culture of chicken pineal gland[11]: (1) In a LD cycle, *N*-acetyltransferase activity continued to oscillate in phase with the lighting schedule for long periods—at least 3 days in the organ culture[11] and 17 days in the dispersed cell culture. However, the amplitude of the rhythm was gradually decreased in the organ culture, presumably due to a necrosis of the gland, while in the dispersed cells the same magnitude of *N*-acetyltransferase activity was maintained during the period examined. (2) When cultured in continuous darkness, the rhythmic changes of *N*-acetyltransferase activity were damped out in both the organ culture and the cell culture. This could be due to desynchronisation of the rhythms in individual cells. (3) Even when lights were turned off during the daytime, *N*-acetyltransferase activity did not increase during the subjective daytime in both organ culture and the cell culture, indicating the endogenous nature of the rhythmicity. (4) Continuous illumination of the glands or the cells suppressed the night-time increase of *N*-acetyltransferase activity, although there were still significant elevations of enzyme activity during the subjective night-time, even under illumination. (5) The rhythmic change of *N*-acetyltransferase activity was entrained to the reversed LD cycle in the dispersed cells, although this was not examined with the organ culture. (6) The night-time level of *N*-acetyltransferase activity in the organ culture was about 3,500 and 1,250 pmol per mg protein per 10 min (700 and 250 pmol per mg pineal per 10 min) in the first and second nights of culture, respectively[11]. The night-time level of enzyme activity in the dispersed cells reported here is 1,500–2,700 pmol per mg protein per 10 min, which is the same as that of organ culture and is close to the *in vivo* rhythm[11]. The daytime activity in the dispersed cells was also comparable to those of intact pineal gland. If the *N*-acetyltransferase rhythm in the dispersed cells is due to the formation of cellular interaction in small clusters, the maximum enzyme activity should be much lower than those of intact glands, because only a portion of the cells form clusters (Fig. 1). To further rule out the possiblity that the reaggregated cells re-establish the specific cell–cell interaction to induce the circadian rhythm of *N*-acetyltransferase activity, dispersed cells were inoculated at different cell populations from 5×10^5 to 4×10^6 cells per dish to give different degrees of reaggregation. Activity of *N*-acetyltransferase showed a similar night-time increase at various cell populations (data not shown).

It has been well demonstrated that, although dispersed embryonic cells reconstruct tissue-like structure in suspension or rotation cultures, the cells rapidly lose the histoformative tendency in monolayer cultures[14–16]. Cells from embryos at a late stage of gestation or from postnatal animals do not show tissue formation in cultures. Thus it is unlikely that the dispersed pineal cells studied here re-established the tissue-like cellular interaction, which in turn generated the *N*-acetyltransferase rhythm. The present observations that the dispersed cells behave in the exactly same manner as the intact pineal glands are very indicative, though not conclusive, that the photoreceptor, the circadian oscillator and the melatonin-synthesising machinery reside in the same cell of chicken pineal gland. This system will offer an ideal model for a long-term study of the circadian oscillator of vertebrates in culture.

I thank Miss E. Amano for technical assistance. This research was supported by grants-in-aid for Special Project Research and for Co-operative Research (no. 237010) from the Ministry of Education of Japan.

Induction of vitellogenin and growth of implanted oocytes in male cockroaches

Eric C. Mundall & Stephen S. Tobe*

Department of Zoology, University of Toronto, Toronto, Ontario, Canada M5S 1A1

Barbara Stay

Department of Zoology, University of Iowa, Iowa City, Iowa 52242

Vitellogenins are yolk protein precursors that are synthesised in the liver of lower vertebrates in response to ovarian hormones[1,2], and in the fat body tissue of insects, under the influence, in most species, of juvenile hormone (JH) from the corpora allata (CA)[3,4]. Vitellogenins are normally restricted to females, although in male amphibians[1] and roosters[2] their synthesis can be induced artificially by the injection of oestrogens. Thus female specificity is maintained by hormonal differences between adult males and females. In insects, on the other hand, because the CA of adults of both sexes are active[4,5], it appeared that male fat body could not normally respond to JH by synthesising vitellogenin. However, precise JH synthetic rates of male CA are only known in *Schistocerca gregaria*[6] and *Diploptera punctata*[7], in which species they are low compared to the rates in the female glands. The absence of vitellogenin in adult males could thus be due to inadequate JH titres. We report here that synthesis of vitellogenin can indeed be induced in males of *Diploptera* by implantation of female CA or application of a JH analogue, ZR512 (Zoecon), and that implanted oocytes take up the vitellogenin.

In preliminary experiments we found that removal of the CA of newly-emerged (day 0) females ($n = 5$) prevented the appearance of vitellogenin on day 6, as determined by rocket immunoelectrophoresis. Also, normal adult males from 6 to 21 days old ($n = 39$) contained no detectable vitellogenin (titres approaching 0.1% that of normal day 6 females, or 10 ng, are detectable by this technique). A pair of CA from day 0 females was then transplanted to day 0 males with or without a single ovary, also taken from day 0 females. Haemolymph of the males was subsequently checked for vitellogenin on days 3–10 by rocket immunoelectrophoresis. We also measured vitellin in the implanted oocytes (after uptake into oocytes, vitellogenin is referred to as vitellin). Vitellogenin was detected in the haemolymph of the CA recipients from day 3 or 4 onward, and reached a peak concentration on day 8 (Fig. 1*a*). In those males that received only CA implants, vitellogenin titres were about twice those of males that received both CA and an ovary. This suggested that the ovary may have removed some of the protein from the haemolymph. Indeed, Fig. 1*b* shows that oocytes contained vitellin, which reached a maximum level by day 9, when approximately 9 μg per ovary was measured. The oocytes themselves grew, with visible yolk granule formation, and had lain down chorion by day 8. However, they were slightly smaller and contained less vitellin than either oocytes of sham-operated females or those implanted into ovariectomised females (Table 1).

When 150 μg of ZR512 was topically applied in 5 μl acetone to day 0 males implanted with an ovary, vitellin levels were much higher by day 8, approaching those of a normal female ovary (Fig. 2*b*). This is consistent with previous findings from this laboratory (unpublished) that ZR512 is a more potent promoter of oocyte growth in allatectomised females than the topically applied naturally occurring JH of *Diploptera* (identified as C_{16}JH ≡ JH III (ref. 8)). On the other hand, haemolymph titres of vitellogenin in ZR512-treated males were comparable to those of males implanted with CA (Fig. 2*a*), suggesting that the limiting step in appearance of vitellin is the synthesis of the yolk protein precursor by the fat body and not its uptake by the oocytes. When acetone alone was applied, no vitellogenin or vitellin was detected and implanted oocytes did not grow.

This is the first conclusive evidence outside Diptera on the induction of vitellogenin in adult male insects. Limited growth of oocytes implanted into males of the cockroach, *Periplaneta americana*, has been reported[9,10] although no vitellogenin

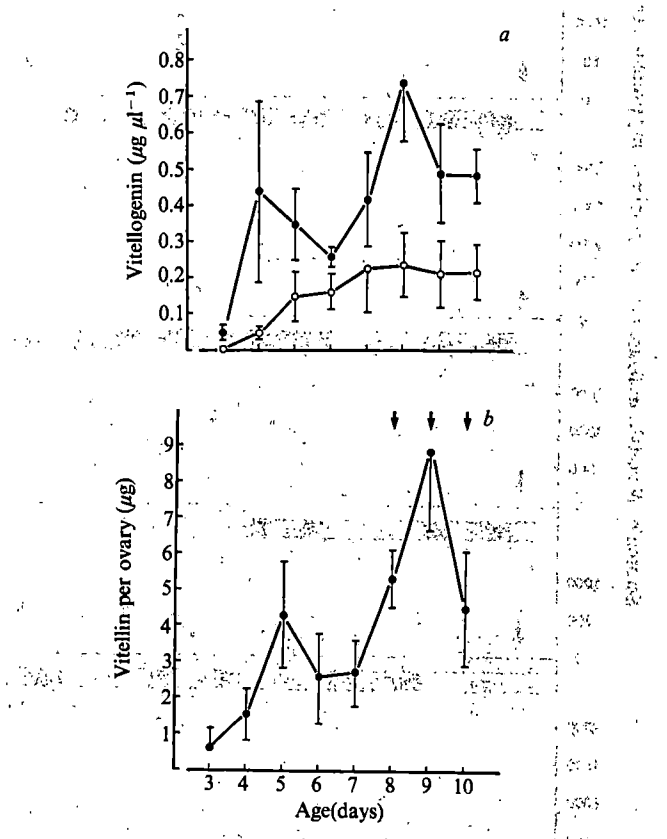

Fig. 1 *a*, Haemolymph vitellogenin concentration in adult males implanted at day 0 with CA of day 0 females, with (○) and without (●) one day 0 ovary (Ov). *b*, Total vitellin in implanted oocytes. The arrows indicate age at which 100% of the oocytes were chorionated. Each point represents the mean of 4–6 determinations (n) except day 10 when $n = 11$. Vertical bars represent one standard error of the mean. Corpora allata were dissected free of adhering fat body tissue and implanted into the neck region of the male recipients. Ovaries were implanted into the abdominal cavity by injection in a small volume of Yeager's Ringer through the intersegmental membrane using a glass needle. Vitellogenin and vitellin titres were determined by rocket immunoelectrophoresis[26]. Antiserum against egg homogenates was raised in rabbits and was rendered specific to vitellin by absorption with male haemolymph. Specificity of the absorbed antiserum was demonstrated by a single immunoprecipitation reaction in agarose against both vitellin of egg extracts and vitellogenin of female haemolymph after separation in polyacryamide gels. Vitellogenin and vitellin were found to be immunologically identical by Ouchterlony double diffusion. Absorbed antiserum was mixed with melted agarose (1% in Tris-buffered 0.025 M Tricine, *p*H 8.6; Bio-Rad) at 50 °C for a final concentration of 0.25–1.00% (v/v), depending on titres of antigen to be tested. Slabs (1.5 mm thick) were then cast, wells cut, and 10-μl samples applied. Electrophoresis was carried out for 12 h at 150 V in a water-cooled chamber (Miles). Immunoprecipitation rockets were quantitated using egg extracts of known protein concentrations as determined by a micro-biuret procedure[27]. Vitellin makes up ~90% of the soluble egg extract (E.C.M., S.S.T. and B.S., in preparation).

synthesis was detected[10]. Similar results were obtained with *Eublaberus posticus*[11]. In another cockroach, *Nauphoeta cinerea*, both ovaries and female CA were implanted into males but no oocyte growth resulted[12]. After transplantation of oocytes to males of the Lepidoptera, *Bombyx mori*[13,14] and *Pieris brassicae*[15], oocyte development took place, but again, no vitellogenin was detected. Conversely, in *Hyalophora cecropia*, vitellin was detected in implanted oocytes[16]. This finding led to the discovery of minute quantities of the yolk protein precursor in normal adult males (0.1% that of females)[16]. Similar quantities were detected in *Oncopeltus fasciatus*[17].

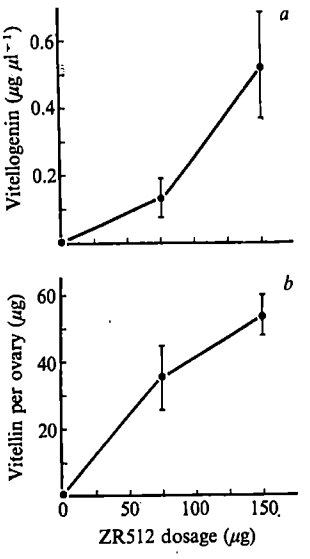

Fig. 2 *a*, Haemolymph vitellogenin concentration in 8-day-old adult males implanted with one ovary at day 0 and topically treated with ZR512 in 5 μl acetone at doses of 75 μg ($n = 8$) and 150 μg ($n = 9$), and with acetone alone ($n = 8$). Procedure as for Fig. 1. *b*, Total vitellin in implanted oocytes on day 8. Procedure as in Fig. 1.

In the Dipterans, *Sarcophaga bullata* and *Drosophila melanogaster*, vitellogenin synthesis in adult males can be induced[18,19]. In *Sarcophaga*, injection of ecdysone reportedly led to the appearance of vitellogenin, whereas JH had no effect. However, implanted oocytes did not mature[18]. In contrast, males of *Drosophilia* were induced to synthesise vitellogenin by implantation of ovaries and oocytes apparently matured completely[20–22]. Synthesis of vitellogenin in *Drosophilia* is reported to require a factor from the ovaries[19] and the ovaries themselves may be a source of vitellogenin[23]. The appearance of vitellogenin in *Diploptera* reported here occurred even when ovaries were not present. Clearly, in Diptera, yolk protein synthesis is controlled differently, both with regard to the role of JH and that of the ovaries.

It is evident that the adult male fat body of *Diploptera* has the capacity to synthesise vitellogenin when stimulated by sufficient titres of JH. It has also been reported that normal adult males of *Rhodnius prolixus* produce yolk protein precursor[24,25], often in amounts similar to females (Engelmann and Mundall, unpublished). These findings, together with the identification of small amounts of vitellogenin in *Hyalophora*[16] and *Oncopeltus*[17] adult males, suggest that the capacity of males to synthesise vitellogenin is not anomalous among insects.

We thank the NIH for a Post-doctoral Fellowship, PHS AM 05350, to E.C.M., and the Natural Sciences and Engineering Research Council of Canada for funds supporting this study.

Table 1 Total vitellin on day 7 in ovaries (Ov) re-implanted into 0 day ovariectomised females (OvX) and those of sham-operated controls*

Treatment	Vitellin (μg per ovary)	*n*
OvX+Ov	84.4±16.2	5
sham-operated	83.2±11.9	5

Values are mean±s.e.m.; *n*, numbers of animals.

Is multiple sulphatase deficiency due to defective regulation of sulphohydrolase expression?

M. B. Fiddler, D. Vine*, E. Shapira† & H. L. Nadler

Children's Memorial Hospital, Division of Genetics, Northwestern University Medical School, 2300 Children's Plaza, Chicago, Illinois 60614

Multiple sulphatase deficiency disease is an unusual autosomal recessive disorder characterised biochemically by a deficiency of several sulphohydrolase activities[1,2]. The laboratory diagnosis of this combined neurological connective tissue disorder is made on the basis of decreased activities of the lysosomal enzymes, arylsulphatase A and arylsulphatase B and the microsomal enzyme, arylsulphatase C. The primary defect in this multienzyme deficiency has not been identified. Using immunological techniques to characterise further the residual activities of arylsulphatases A and B in the multiple sulphatase deficiency disease, we have examined the levels of cross-reacting material (CRM) to arylsulphatases A and B in cultured skin fibroblasts from controls and patients with multiple sulphatase deficiency, metachromatic leukodystrophy (deficiency of only arylsulphatase A activity) and Maroteaux–Lamy syndrome (deficiency of only arylsulphatase B activity). We report here results indicating that arylsulphatases A and B in multiple sulphatase deficiency are reduced in their levels of CRM while retaining a normal activity/CRM ratio. Because the two enzymes are apparently structurally unrelated, these data are consistent with the possibility that their combined deficiencies in this disorder may result from a defect in the coordinated expression of sulphohydrolases.

Skin fibroblasts from patients with multiple sulphatase deficiency ($n = 3$), metachromatic leukodystrophy ($n = 2$) and Maroteaux–Lamy syndrome ($n = 2$), as well as controls ($n = 5$), were grown as previously described. Cultures were also maintained in HEPES-CO_2 as described by Fluharty *et al.*[3], who reported that with growth in this medium, arylsulphatases A and B in multiple sulphatase deficiency returned to normal activity levels: we failed to confirm this observation. Cells were collected by trypsinisation at confluency and lysates containing arylsulphatases A and B were obtained by freeze–thaw and centrifugation. Enzyme assays confirmed the diagnosis of multiple sulphatase deficiency; compared with control, lysates from multiple sulphatase deficiency cell line 1 had <1% arylsulphatase A, ~5% arylsulphatase B; those from multiple sulphatase deficiency cell line 2 had ~7% arylsulphatase A, ~10% arylsulphatase B; and those from multiple sulphatase deficiency cell line 3 had ~5% arylsulphatase A, ~10% arylsulphatase B; arylsulphatase C was 40–60% of control in these lines. In some experiments, arylsulphatase A and B activities were separated by anion exchange chromatography[2]. No cross-reactivity was observed between purified arylsulphatase A and arylsulphatase B to anti-arylsulphatase A and anti-arylsulphatase B, respectively, and therefore intact lysates were also used. Ouchterlony double diffusion demonstrated single lines of identity between normal fibroblast lysates and lysates from multiple sulphatase deficiency cells when tested with either anti-arylsulphatase A or anti-arylsulphatase B. These results validated the use of more quantitative tests to measure the relative levels of CRM to arylsulphatases A and B in the various cell lines.

Figure 1 shows the results of single radial immunodiffusion (SRID) assays[4]. Figure 1*a* plots the anti-arylsulphatase A as ring area against activity. Lysates from multiple sulphatase deficiency cells fell on the same line as controls and Maroteaux–Lamy syndrome cells, whereas the slope for lysates from metachromatic leukodystrophy cells was steeper, indicating considerably less enzymatic activity per CRM than controls, multiple sulphatase deficiency or Maroteaux–Lamy syndrome. Figure 1*b* plots the anti-arylsulphatase A assay ring area against protein in the assayed samples. The multiple sulphatase deficiency lysate fell below the line obtained for control, metachromatic leukodystrophy and Maroteaux–Lamy syndrome lysates. Figure 1*c*, *d* illustrates the data obtained for SRID assays carried out with anti-arylsulphatase B. The data are plotted as described above for anti-arylsulphatase A, with similar results in both plots for two multiple sulphatase deficiency lysates. In this assay, Maroteaux–Lamy syndrome lysates showed considerably lower activity/CRM ratios than controls, multiple sulphatase deficiency and metachromatic leukodystrophy (Fig. 1*c*). Taking all the results of Fig. 1 together, the following conclusions may be made. (1) Arylsulphatase A and arylsulphatase B from multiple sulphatase deficiency cells are similar to controls with respect to enzymatic activity per unit CRM; (2) arylsulphatases A and B are reduced in their CRM levels (in approximate proportion to the decrease in the activity observed in lysate enzyme assays) and, in contrast, (3) the arylsulphatase A in metachromatic leukodystrophy lysates and the arylsulphatase B in Maroteaux–Lamy syndrome lysates are markedly reduced in the CRM-specific enzymatic activity, although CRM to each enzyme is found at normal levels in the cells.

To confirm the observation that the CRM/activity ratio of arylsulphatases A and B in multiple sulphatase deficiency cells was comparable to that observed with normal enzyme, a sensitive competitive precipitin assay was carried out (see Fig. 2 legend for assay method). In Fig. 2, the curves described as 'expected' (×) in each graph represent the anticipated values of residual supernatant activity if the multiple sulphatase deficiency activities have a normal ratio of activity to CRM. Values significantly above expected would indicate the presence of higher amounts of CRM than indicated by the level of enzymatic activity. For both arylsulphatases A and B, values at all antibody concentrations were very close to expected. Identical agreement to expected was also obtained when the level of multiple sulphatase deficiency activity was one-half the normal activity in the assay. These results confirm the findings of the SRID assay in that the enzyme which is present in multiple sulphatase deficiency cells seems to be normal in its ratio of activity to CRM and thus, by implication from this assay, is reduced in the level of arylsulphatases A- and B-specific CRM in the cell.

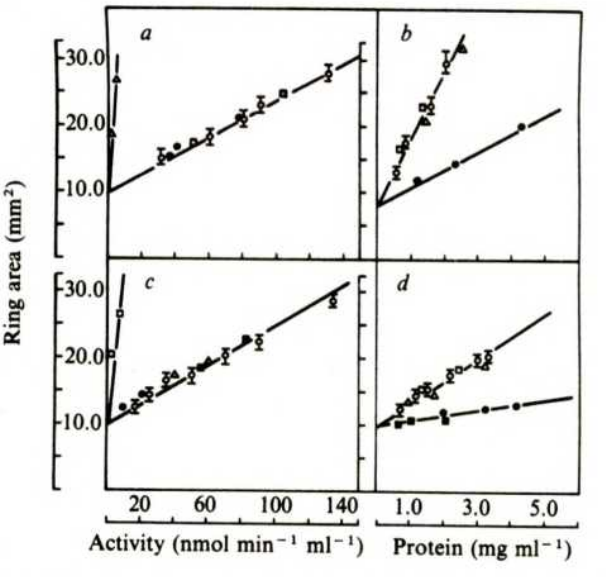

Fig. 1 Single radial immunodiffusion (SRID) assays of fibroblast lysates from controls and patients with multiple sulphatase deficiency, metachromatic leukodystrophy and Maroteaux–Lamy syndrome. Antibodies to purified human liver arylsulphatase A and arylsulphatase B were raised in rabbits by multi-site injection with Freund's complete adjuvant. Arylsulphatase A and B activities were assayed as previously described[9]. Arylsulphatase B was purified as previously reported[10], and arylsulphatase A was purified as follows. Liver was obtained at autopsy, homogenised in 10 mM Tris-HCl, *p*H 7.4 (2:1 v/w), frozen and thawed three times, sonicated briefly, and filtered through gauze; the homogenate was mixed at 4 °C with DE-cellulose equilibrated with the above buffer (1 g DE-cellulose per 2 g wet weight tissue). The adsorbed fraction, free of arylsulphatase B, was eluted batchwise with 1.0 M NaCl, the *p*H was adjusted to 6.0 and the fraction was mixed at 4 °C and 2 g concanavalin A bound by CNBr (ref. 11) to 200 ml Sepharose. The adsorbant was then poured into a column, washed with 20 mM Tris-acetate, *p*H 6.0 and 0.5 M NaCl, and enzyme was eluted with 1.0 M α-CH_3-glucoside, *p*H 7.4, at 22 °C. Activity fractions were concentrated by negative pressure ultrafiltration, dialysed against 20 mM Tris-acetate, *p*H 6.0, and applied to a column of Cibacron Blue–GioGel 0.5 M (100 cm × 2 cm)[12]. Peak fractions were pooled and fractionated on a DE-cellulose column, equilibrated in 10 mM Tris-HCl, *p*H 7.6, and eluted by a 0–500 mM NaCl linear gradient. Final purification was accomplished by fractionation on a column of BioGel P-150 (90 cm × 1.0 cm) at *p*H 7.4 (50 mM Tris-HCl). Purity of the enzyme was demonstrated by polyacrylamide electrophoresis[13] and a symmetrical peak of constant specific activity on gel filtration. Antibodies to arylsulphatase A and arylsulphatase B and their respective IgG fractions prepared by precipitation of the antiserum with 40% saturated ammonium sulphate, appeared monospecific by immunoelectrophoresis against the original liver material. These assays were carried out in Petri plates of 1.5% agarose (12 ml) containing 225 μg ml^{-1} anti-arylsulphatase A IgG or 125 μg ml^{-1} anti-arylsulphatase B IgG and 0.02% NaN_2; 7-μl samples were applied to each well and allowed to diffuse for 48 h at 37 °C. Plates were washed in phosphate-buffered saline for 72 h and, to increase the sensitivity of the assay, a second antibody, goat-anti-rabbit IgG, was applied to each well and allowed to diffuse in a similar manner. Antibody–antigen precipitin rings were measured with a Bausch and Lomb calibrated eyepiece. *a*, *b*, SRID using anti-arylsulphatase A (anti-ASA); *c*, *d*, SRID using anti-arylsulphatase B (anti-ASB). Scale for protein represents actual values for SRID with anti-arylsulphatase A and standardisation to 1.0 mg ml^{-1} for anti-arylsulphatase B (actual values = ×3). ○, Controls (±range, $n = 4$); ■, multiple sulphatase deficiency, cell line 1; ●, multiple sulphatase deficiency, cell line 2; △, metachromatic leukodystrophy; □, Maroteaux–Lamy syndrome. (The results from two mutant lines are pooled for metachromatic leukodystrophy and Maroteaux–Lamy syndrome.)

To examine the possibility that the intracellular activities of arylsulphatases A and B in multiple sulphatase deficiency are reduced because of excessive secretion into the media, control and multiple sulphatase deficiency fibroblasts (cell lines 2 and 3) were examined for levels of arylsulphatase A and B activities in serum-free media in conditions previously described[5]. No differences in arylsulphatase A or B activities were observed between control and multiple sulphatase deficiency cells (~10 nmol per min per mg cell protein). In addition, no differences were observed in the migration of arylsulphatase A and B activities from control and multiple sulphatase deficiency lysates on polyacrylamide gel electrophoresis at *p*H 4.1.

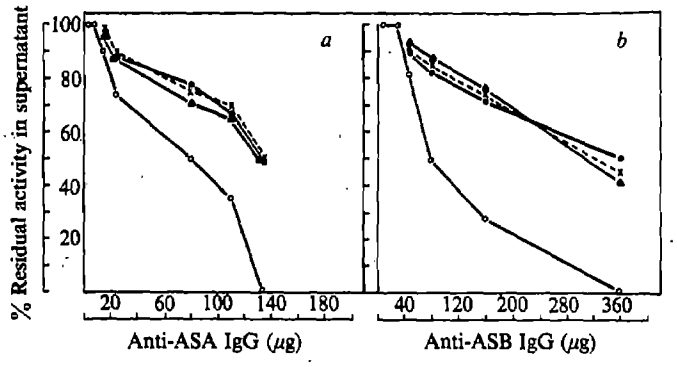

Fig. 2 Competitive precipitin assays of multiple sulphatase deficiency compared with control fibroblast lysates. A precipitin curve for normal enzyme was first established. Increasing amounts of antibody were added to a constant amount of cell lysate (that is, a constant level of activity), incubated first at 37 °C for 120 min then at 4 °C for 16 h. A previously formed complex (100 μg) of human serum albumin (HSA)–anti-HSA was added to each tube as a carrier protein, the mixture centrifuged at 10,000*g* for 20 min and the supernatants assayed for unprecipitated enzymatic activity. Equal levels of enzymatic activity from multiple sulphatase deficiency lysates were then added to tubes containing the previously defined ratio of antibody to normal cell lysate. *a*, Assay of arylsulphatase A using anti-arylsulphatase A; *b*, assay of arylsulphatase B using anti-arylsulphatase B. ○, Control; ●, multiple sulphatase deficiency, line 2; ▲, multiple sulphatase deficiency, line 3; ×, expected values (see text for discussion).

Hypotheses to explain the defect in MSD include (1) a mutation in a subunit or 'factor' common to the sulphohydrolases; (2) the presence of an inhibitor of the affected sulphohydrolases derived from a defect in another metabolic pathway; (3) a defect in a cellular process which coordinately regulates (pre- or post-translationally) the expression of sulphohydrolases. The demonstration that catalytically normal arylsulphatases A and B are present in reduced concentrations in multiple sulphatase deficiency is most consistent with the third hypothesis; these findings are also supported by recent immunological studies by Fluharty *et al.*[3], who observed reduced levels of CRM to arylsulphatase A in multiple sulphatase deficiency. It cannot be determined, however, whether arylsulphatases A and B are decreased in their synthesis or increased in their rate of degradation; the latter may occur, for instance, through a mutation in a putative stabiliser molecule common to the enzymes, a defect which may result in a decay of the sulphatases at both the antigenic and activity levels. These findings in multiple sulphatase deficiency are in contrast to the apparent mutation in the structural genes for arylsulphatase A in metachromatic leukodystrophy and arylsulphatase B in Maroteaux–Lamy syndrome[6]. The recent localisation of arylsulphatase A to chromosome 22 and arylsulphatase B to chromosome 5, as well as the independent expression of each enzyme, provides evidence against a common structural feature between the two enzymes[7]. It is difficult to reconcile our findings with either of the first two explanations. Although mucolipidosis II (I-cell disease) is characterised by the intracellular deficiency of several lysosomal enzymes in cultured skin fibroblasts, the majority of these enzymes may be accounted for by their elevated levels extracellularly[8]. Thus, these studies suggest the existence of a unique monogenic disorder in humans which is the result of a defect in a process which coordinates the expression of several enzymes.

We thank Ms S. S. Loo and Mr P. Johnson for technical assistance. Multiple sulphatase deficiency fibroblast lines were obtained from the Mutant Cell Repository, Camden, New Jersey and as a gift from Dr A. Fluharty. This work was supported by the National Foundation-March of Dimes.

Inefficient lactate dehydrogenases of deep-sea fishes

George N. Somero & Joseph F. Siebenaller*

Scripps Institution of Oceanography, University of California, San Diego, La Jolla, California 92093

The respiratory rates of deep-sea animals are extremely low. Deep-sea fishes may consume oxygen at rates only 5–10% those characteristic of shallow-water species[1–4]. These low metabolic rates are probably an adaptation to the presumed scarcity of food in deeper water[4]. The biochemical basis of this metabolic adaptation is a low level of enzyme activity in the skeletal muscle (but not the heart or brain), mainly because of the low enzyme concentrations in that tissue[5]. We report here, however, that a second source of reduced enzyme activity contributes to the low metabolic rate. For muscle-type (M_4) lactate dehydrogenases (LDH, EC 1.1.1.27, NAD^+:lactate oxidoreductase), the enzymes of deep-sea fishes have significantly higher activation free energy (ΔG^*) and enthalpy (ΔH^*) characteristics than the homologous enzymes of cold-adapted, shallow-water fishes. Because of these higher energy barriers to catalysis, pyruvate is reduced to lactate at approximately 60% of the rate observed with LDHs of shallow-water fishes. Thus, in terms of rate of function per enzyme molecule, deep-sea fishes would be at a disadvantage in shallow waters because of their relatively poor capacity for muscle glycolysis. Such enzymatic factors may help determine the upper distributions of deep-sea species, much as the relatively large pressure insensitivities of LDHs of these deep-sea fishes[6,7] may enable them to tolerate high and variable pressures. We suggest that the low catalytic efficiencies of high-pressure-adapted LDHs are concomitant with their low sensitivities to pressure.

* Present address: Department of Ecology and Evolution, State University of New York, Stony Brook, New York 11794.

Studies of homologous enzymes from animals adapted to different temperatures have shown that ΔH^* and ΔG^* are lowest for reactions of the most cold-adapted species[8–12]. These differences influence reaction rates and are viewed as adaptive, as the lower energy barriers in cold-adapted animals facilitate metabolic rate compensation to temperature. Because the temperatures of the deep sea average only 2–5 °C (ref. 13), one might predict, on the basis of temperature adaptation studies, that deep-sea animals would possess highly efficient enzymes. For M_4-lactate dehydrogenases this expectation is not realised (Fig. 1, Table 1). The Arrhenius activation energies (E_a) of the deep-sea species are homogeneous (analysis of variance (ANOVA), $F_{[3,19]} = 0.99$, $0.5 < P < 0.25$), and the E_a of the shallow-living, cold-adapted species are homogeneous ($F_{[1,19]} = 2.24$, $0.25 < P < 0.10$). However, the E_a values of the deep and shallow species groups differ ($F_{[1,19]} = 9.09$, $P < 0.01$). The M_4-LDHs of deep-sea teleosts belonging to four families are consistently found to have higher activation energy characteristics and lower rates of activity per enzyme molecule (Table 1; see legend for computation procedures) than the M_4-LDHs of shallow-living, cold-adapted species. When compared at 5 °C and 1 atm pressure, M_4-LDHs of deep-sea fishes reduce pyruvate to lactate at only about 60% of the rate of LDHs of cold-adapted, shallow-living fishes (Table 1). Thus deep-sea fishes seem to have a low capacity for anaerobic glycolysis, in comparison with shallow species, in conditions of low hydrostatic pressure and low temperature. However, at deep-sea pressures, the reduced pressure sensitivities of M_4-LDHs of deep-sea fishes may compensate for the low efficiencies of these enzymes[6,7]; at these pressures M_4-LDHs of shallow-living fishes show significant velocity inhibition and perturbation of K_m values[6,7].

The importance of hydrostatic pressure as a selective factor in enzyme evolution is shown particularly clearly by the M_4-LDHs of the two *Sebastolobus* congeners, *S. alascanus* (shallow) and *S. altivelis* (deep). These two species are very similar morphologically and ecologically[6,14], but they experience different pressure regimes at their depths of maximal abundance (Table 1). The difference in habitat pressure (of the order of 50–100 atm, corresponding to differences of 500–1,000 m in depths of distribution) seems to be large enough to involve selection for altered activation parameters, as well as for different pressure sensitivities in K_m values for pyruvate and NADH[6,7]. Despite these significant differences in kinetic properties, M_4-LDHs of the two species could not be distinguished by any of the electrophoretic procedures we reported previously[6]. Evidently, such electrophoretic identity may belie important functional differences between homologous enzymes.

There could be several possible explanations for reduced catalytic efficiencies of enzymes of deep-sea animals. First, if reduced metabolic rates in such a food-poor environment are selectively advantageous, then selection might favour enzymes having relatively low rates of activity[15]. However, we do not support this interpretation, as reduced metabolic activity could be achieved more economically by maintaining lower concentrations of more efficient enzymes. Comparisons of muscle enzyme activities (including LDH) in deep- and shallow-living fishes have shown that enzymatic protein concentrations decrease rapidly as a function of the species' minimal depths of occurrence[5]. The approximately 60% reduction of LDH activity due to inefficiency of this enzyme in deep-sea fishes could well be achieved by enzyme dilution in the cells, as an approximately 25- to 50-fold reduction in LDH activity has already been

Table 1 Activation energy parameters and relative absolute velocities of M_4-lactate dehydrogenase reactions of differently temperature- and pressure-adapted fishes and a mammal

Species* (Depth range/body temperatures)	E_a† (cal mol^{-1})	ΔH^* (cal mol^{-1})	ΔS‡ (cal mol^{-1} K^{-1})	ΔG^*‡ (cal mol^{-1})	Relative velocity‡
Pagothenia borchgrevinki (surface/−2 °C)	11,020 (197)	10,467	−12.7	14,000	1.00
Sebastolobus alascanus (180–440 m/4–12 °C)	11,068 (196)	10,515	−12.6	14,009	0.98
Sebastolobus altivelis (550–1,300 m/4–12 °C)	12,538 (216)	11,985	−8.1	14,249	0.64
Coryphaenoides acrolepis (1,460–1,840 m/2–10 °C)	12,366 (220)	11,813	−8.7	14,222	0.67
Halosauropsis macrochir (~2,300 m/2–5 °C)	12,396 (259)	11,843	−8.6	14,227	0.66
Antimora rostrata (1,300–2,500 m/2–5 °C)	13,110 (223)	12,557	−6.4	14,343	0.54
Thunnus thynnus (bluefin tuna) (surface <300 m/15–30 °C)	11,937 (153)	11,384	−10.0	14,152	0.76
Rabbit (37 °C)	13,100	12,550	−6.4	14,342	0.54

* The depth ranges given for the species are the depths of maximal abundances (see refs 4, 6 and 7 for additional data). For the analysis of variance tests, *P. borchgrevinki* and *S. alascanus* were the shallow-living species, and *S. altivelis, H. macrochir. A. rostrata* and *C. acrolepis* were the deep-living species.

† The Arrhenius activation energy (E_a) values were computed from the slopes, determined by linear regression, of plots such as those shown in Fig. 1. Standard errors for the E_a values are given in parentheses beneath the E_a values. The activation enthalpy (ΔH^*) values are for 5 °C ($\Delta H^* = E_a - RT$).

‡ Estimates of ΔS^* and ΔG^* were computed using the following rationale. For all sets of homologous enzymes that have been studied to determine activation parameters, a highly regular covariation between ΔH^* and ΔS^* has been found[8–12]. For LDHs a plot of ΔH^* against ΔS^* gives a slope of approximately 330 K (refs 9, 11). This slope is called the 'compensation temperature' (ref. 20) to emphasise that simultaneous increases in ΔH^* and ΔS^* have compensating–offsetting effects on $\Delta G (\Delta G^* = \Delta H^* - T\Delta S^*)$. We assume that all of the M_4-LDHs used in this study fit the compensation relationship noted for other vertebrate M_4-LDHs. On this assumption we have estimated ΔS^* values, using experimentally determined differences in ΔH^*, and the experimentally determined ΔS^* from ref. 10 for flounder M_4-LDH (the ΔH^* reported for the latter enzyme is 10,500 cal mol^{-1}). For each 330 cal mol^{-1} increment in ΔH^*, the compensation relationship predicts a 1 entropy unit (cal mol^{-1} K^{-1}) increase in ΔS^*. Thus, using the flounder M_4-LDH reaction as a baseline, we have computed the other ΔS^* values and, using these, the ΔG^* values. The relative velocity values are the reaction rates computed from the differences in ΔG^* among the M_4-LDHs, using the reaction rate of the *Pagothenia* M_4-LDH reaction (the reaction having the lowest ΔH^* and ΔG^* values) as the reference (value = 1.0). The calculated relative rates agree extremely well with experimentally determined rates for the M_4-LDH reactions of *Sebastolobus alascanus* and *S. altivelis*. The specific activities of these two enzymes, in μmol NADH oxidised to NAD$^+$ per mol LDH per min, are 4.66×10^{10} and 2.82×10^{10}, respectively at 5 °C and 1 atm pressure. Protein concentrations were determined by the technique of Sedmak and Grossberg[22], using bovine serum albumin as a standard. Our decision to estimate ΔG^* values using the compensation relationship rather than through direct experimental measurement of velocities and protein concentrations is based on the fact that small amounts of enzymatically inactive protein can greatly distort specific activity values, whereas a high degree of precision is possible in the measurement of ΔH^* values. The regression coefficients for all Arrhenius plots were greater than 0.996. Our value for the ΔH^* of the *Antimora rostrata* M_4-LDH reaction is in excellent agreement with the value reported by Baldwin *et al.*[15]; they obtained values for E_a and ΔH^* of 13,200 and 12,648 cal mol^{-1} (at 5 °C), respectively. Their experimentally determined substrate turnover number for the *A. rostrata* enzyme (2.48×10^{10} μmol NADH oxidised to NAD$^+$ per mol LDH per min) is also in excellent agreement with the relative rate calculated from the activation parameters. The bluefin tuna data are from ref. 23. The rabbit data (obtained using a phosphate buffer system) are from ref. 9.

achieved through maintenance of low enzyme concentrations[5]. The alternative explanation we propose to account for the high activation parameters of enzymes from high-pressure-adapted organisms is based on an analogy between high temperature and high pressure effects on enzymes. For enzymes of high body temperature species like mammals, a concomitant of low catalytic efficiency (Table 1) is a high degree of structural stability; for example, a high resistance to thermal denaturation[8,11,12]. This relationship has been found for LDHs, and has been interpreted in terms of additional weak bonds, for example, hydrogen bonds, stabilising the mammalian enzyme–cofactor–substrate ternary complex relative to the complex formed with a fish LDH[11]. Elevated hydrostatic pressures may also favour selection for more structurally stable enzymes which, like the enzymes of high body temperature species, also have reduced catalytic efficiencies. In fact, the M_4-LDHs of the four deep-sea fishes have efficiencies similar to that of a mammalian M_4-LDH (Table 1).

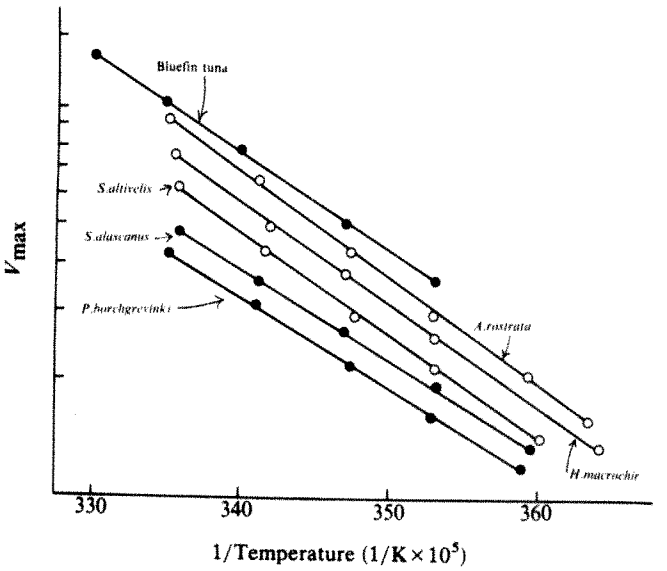

Fig. 1 Arrhenius plots (log V_{max} against reciprocal of absolute temperature (K)) for M_4-lactate dehydrogenase reactions of several deep-sea and shallow-living teleost fishes. The V_{max} values were determined using M_4-isozymes of LDH purified by oxamate affinity chromatography. Purification details are given in ref. 7. LDH activity was assayed by following the decrease in absorbance at 340 nm due to oxidation of NADH in a thermostatted spectrophotometer. Cuvette temperatures were held within ±0.2 °C of the stated temperatures. The assay medium contained 80 mM imidazole/HCl buffer, adjusted to *p*H 6.98 at 20 °C. At all of the other experimental temperatures, the *p*H of this imidazole buffer system follows the intracellular *p*H of ectothermic vertebrates (see ref. 8). The NADH concentration was 150 μM. At each temperature 6–9 pyruvate concentrations were used to determine theoretical V_{max}. Data were analysed using the weighted linear regression technique of Wilkinson[19]. Note that the plots are positioned on the axes to show differences in slope, so the V_{max} values do not reflect the actual differences in substrate turnover number (see Table 1) of the LDHs of the shallow-living (●) and deep-living (○) fishes.

The differences in kinetic properties between M_4-LDHs of shallow- and deep-living species suggest that enzymatic adaptations may be important in establishing bathymetric distribution patterns (although biological interactions must also have an important role). Pressure-sensitive K_m values of LDHs of shallow-living fishes may make these enzymes unsuitable for function at high and/or variable pressures, and thus might help restrict the depth distributions of these species[6,7,21]. On the other hand, even though the M_4-LDHs of deep-living fishes are very insensitive to pressure and would seem on this basis to be able to function at both shallow and great depths, the catalytic inefficiencies of these enzymes may place them at a significant disadvantage at low pressures. To possess the same glycolytic capacity as a shallow-water fish, a deep-sea fish would have to maintain a high -concentration of LDH molecules in its cells, a demand which is at odds with the low protein concentrations of the muscle fluids of these species[5,7,16,17].

We thank Drs Richard Haedrich, John Stegeman and Jonathan Wittenberg for providing *Halosauropsis* specimens. These studies were supported by NSF grant PCM-7804321 and BRSG grant RR-07011 awarded by the Division of Research Resources of the NIH.

Post-transcriptional control in the early mouse embryo

Peter Braude, Hugh Pelham, Gin Flach & Rita Lobatto

Departments of Anatomy and Biochemistry, University of Cambridge, Downing Street, Cambridge, UK

The earliest stages of mouse embryogenesis, from fertilisation to the two-cell stage, are characterised by an extremely low level of RNA synthesis. Indeed, during this period, RNA polymerase II activity[1] and incorporation of labelled precursors into heterogeneous RNA[2] are not detectable, and there is no increase in the poly(A) content of the embryo, but rather a slight decrease[3]. The rate of protein synthesis remains low and relatively constant throughout the one- and two-cell stages[4]. However, qualitative analysis of the protein synthetic profile on SDS gels has revealed changes which appear around the late one-cell to early two-cell stage[4–6]. This early change in the pattern of polypeptide synthesis represents the first major qualitative molecular change found so far in development. We present evidence which suggests that the increased synthesis at the early two-cell stage of a small number of polypeptides of molecular weight 35,000 is not dependent on transcription, but rather represents control at a post-transcriptional level using mRNAs synthesised before fertilisation.

Figure 1*a* shows the pattern obtained when newly fertilised embryos were labelled for 3 h with ^{35}S-methionine and the radioactive polypeptides separated on a two-dimensional gel of the O'Farrell type[7]. Although there are a few notable differences between this and the pattern obtained from unfertilised eggs (Fig. 2*a*) the patterns are remarkably similar. The corresponding pattern from early two-cell embryos is shown in

Fig. 1*b*. It is clear that most of the polypeptides that are made immediately after fertilisation continue to be synthesised at the two-cell stage. In addition, among the changes which can be observed at least three polypeptides (arrowed) with molecular weights around 35,000 are made in greatly increased amounts at the later time.

If this increase was due to the *de novo* synthesis of mRNA, it should be possible to block the changes by adding a specific inhibitor of transcription. A suitable inhibitor is α-amanitin, which at levels of 10–100 $\mu g\,ml^{-1}$ specifically blocks mRNA synthesis, inhibits RNA polymerase II[1,8–10] and has been shown to be effective at these doses in early mouse embryos[11,12]. The presence of 11 $\mu g\,ml^{-1}$ α-amanitin in the culture medium did not prevent the first cell division, and Fig. 1*c* shows that it also did not block the appearance of the characteristic early two-cell polypeptides. This result was found in four separate experiments and also when 100 $\mu g\,ml^{-1}$ α-amanitin was used (data not shown). However, before it can be concluded that control of the synthesis of the three polypeptides is at a post-transcriptional level, it is necessary to demonstrate that the inhibitor actually enters the cells.

As the incorporation of radioactive precursors into mRNA is undetectable over the period being studied, an indirect approach had to be adopted. It has been widely reported that α-amanitin can arrest or markedly retard cleavage in preimplantation mouse embryos[11,13–15]. Since α-amanitin is an irreversible inhibitor[16], a brief early pulse of the drug at the one-cell stage should produce effects at a later stage of development when transcription is required. As one-cell embryos from CFLP mice do not readily develop *in vitro* beyond the two-cell stage, embryos from B10 × CBA F_1 hybrids (courtesy of Dr M. H. Kaufman) were used. Table 1 shows the results from such an experiment in which newly fertilised eggs were pulsed with 11 $\mu g\,ml^{-1}$ α-amanitin for 6 h before they were transferred to fresh medium free of α-amanitin and allowed to develop further *in vitro*. None of the α-amanitin-treated embryos progressed beyond the two-cell stage, whereas 82% of the control embryos which reached the two-cell stage developed to the three- or four-cell stage within 56 h of fertilisation.

From this we conclude that α-amanitin does enter one-cell embryos, and that transcription by RNA polymerase II is not required for the first cell division. We also conclude from Fig. 1 that most of the mRNAs present at fertilisation are still active some 24 h later, at the early two-cell stage, and that the appearance of the new polypeptides at this stage is not due to synthesis of new mRNAs by RNA polymerase II. The changes in polypeptide synthetic profile probably therefore represent either post-transcriptional control or α-amanitin resistant transcription, as for example from a viral or mitochondrial genome.

To distinguish transcriptional from post-transcriptional control we investigated whether mRNAs coding for the 35,000-molecular weight polypeptides were present (but not translated) in unfertilised eggs. Total RNA was extracted from about 200

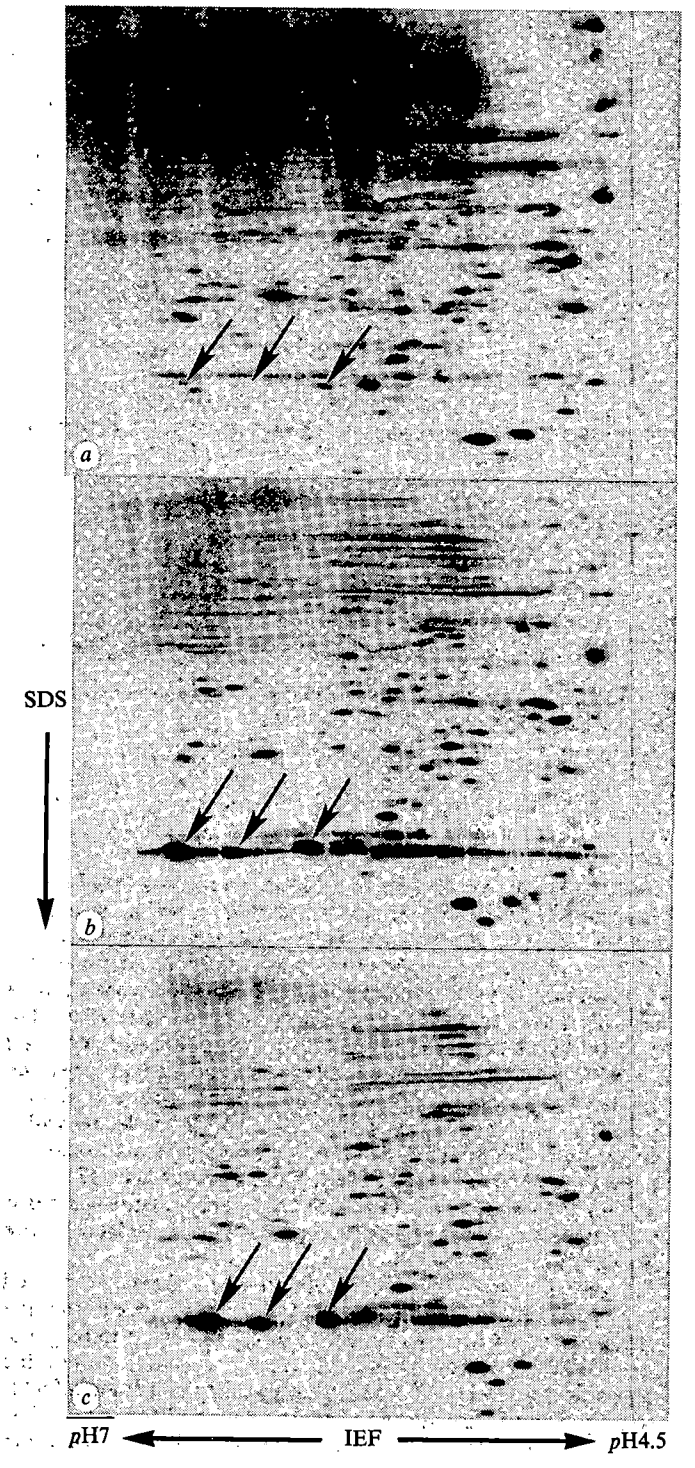

Fig. 1 Two-dimensional fluorographs of ^{35}S-methionine-labelled polypeptides from fertilised eggs (*a*), two-cell embryos having been cultured for 24 h *in vitro* from the one-cell stage (*b*), and two-cell embryos having been cultured for 24 h *in vitro* from the one-cell stage in the presence of 11 $\mu g\,ml^{-1}$ α-amanitin (*c*). Cumulus masses were recovered at 14 h after HCG from the oviducts of superovulated female CFLP mice which had been mated with CFLP males. The cumulus cells were removed by brief treatment in hyaluronidase (1 $mg\,ml^{-1}$), and were then washed through several changes of phosphate-buffered medium (PBM) containing 10% fetal calf serum[20]. The pooled embryos were divided randomly into three groups; dead or disorganised embryos being excluded. One group was incubated for 3 h in 100 μl of medium 16 + 4 $mg\,ml^{-1}$ bovine serum albumin[21] with 10 μl of ^{35}S-methionine (~5 $mCi\,ml^{-1}$). At the end of this period 30 unfertilised eggs were transferred to 20 μl lysis buffer and stored at −70 °C. The presence of two pronuclei and a second polar body was taken as evidence of fertilisation. The remaining two groups were incubated for 24 h in 100 μl drops of medium 16 + BSA in the presence or absence of 11 $\mu g\,ml^{-1}$ α-amanitin. At the end of the culture period the embryos were scored for stage of development and 10 μl of ^{35}S-methionine was added to each drop. After a further 3 h the two-cell embryos in each group were collected in 20 μl of lysis buffer. All incubations were performed at 37 °C in an atmosphere of 5% CO_2 in air. Two-dimensional polyacrylamide electrophoresis in denaturing conditions was carried out over a *p*H range of 4.5 to 7 for the first dimension and an SDS gradient of 7–15% acrylamide for the second as described previously[13,22]. The gels were impregnated with 2,5-diphenyloxazole[23] and exposed to preflashed[24] Fuji Rx X-ray film for between 2 and 6 weeks. Analysis of the film was performed as described previously[13]. The arrows indicate polypeptides weakly labelled in the fertilised egg but strongly labelled at the two-cell stage both in the presence or absence of α-amanitin.

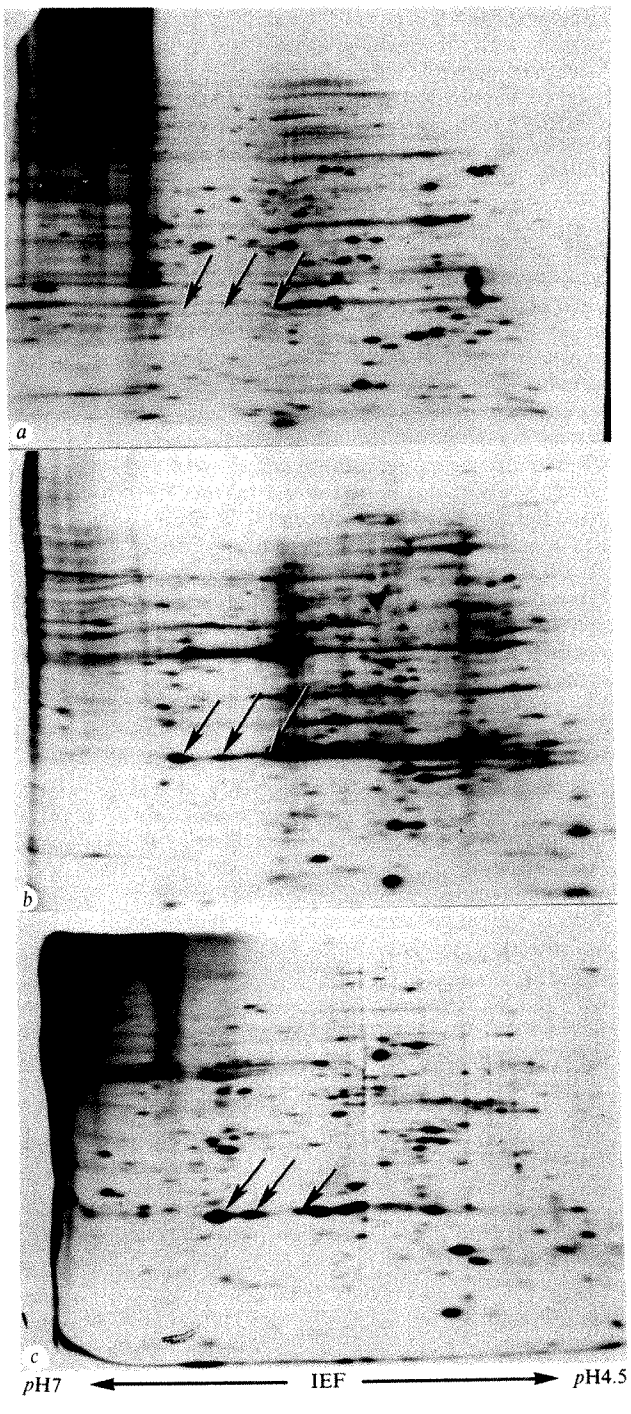

Fig. 2 Two-dimensional fluorographs of ^{35}S-methionine-labelled polypeptides from 60 intact unfertilised eggs (*a*), mRNA from 200 unfertilised eggs translated *in vitro* (*b*), and from 50 intact early two-cell embryos (*c*). Cumulus masses were recovered at 15 h after HCG from the oviducts of superovulated female CFLP mice. The cumulus cells were removed (as for Fig. 1), and 60 unfertilised eggs were labelled for 3 h in medium containing ^{35}S-methionine (as for Fig. 1). mRNA from 200 eggs was extracted and translated in a specially modified message-dependent reticulocyte lysate system as described previously[17]. Two-cell embryos were flushed from the oviducts of superovulated mice 40 h after HCG and labelled as for the unfertilised eggs. Two-dimensional electrophoresis and processing was as for Fig. 1. The arrows show polypeptides which are not strongly labelled until the two-cell stage but are translated *in vitro* from egg mRNA.

Table 1 Development of B10×CBA 1-cell embryos* in the presence of 11 μg ml^{-1} α-amanitin for 6 h

Stage	−α-amanitin		+α-amanitin	
	48 h post HCG	68 h post HCG	48 h post HCG	68 h post HCG
1-cell	17	10	18	14
2-cell	23	5	25	29
3-cell	0	3	0	0
4-cell	0	20	0	0
Dead/disorganised	2	4	2	2
Total	42	42	45	45

Embryos were washed in medium free of α-amanitin at 24 h post HCG and examined at 48 and 68 h post HCG.
* 18 h after HCG administration.

unfertilised eggs and translated in the mRNA-dependent reticulocyte lysate system as described previously[17]. Figure 2 shows a comparison between the products obtained by *in vitro* translation and the polypeptides labelled in either intact unfertilised eggs or early two-cell embryos. The two-cell marker proteins (arrowed) were prominent amongst the cell-free products, even though they were virtually undetectable in the unfertilised egg pattern. This result was consistently found in eight experiments. It could perhaps be argued that the cell-free system might selectively translate the mRNAs for these polypeptides. However, preliminary experiments indicate that these polypeptides are no more prominent among the translation products of RNA from two-cell embryos (data not shown).

Thus, there are a few polypeptides which are prominent products of the early two-cell mouse embryos but which are only very minor products of unfertilised or newly-fertilised eggs. The appearance of these polypeptides is not blocked by the transcriptional inhibitor α-amanitin, and mRNAs coding for them are present in unfertilised eggs. Although we cannot absolutely exclude the possibility of a rapid transcriptional event occurring at fertilisation before the eggs can be transferred into the α-amanitin it seems reasonable to conclude that the increased synthesis of these polypeptides is under post-transcriptional control[18]. Several mechanisms for this type of control could operate[19]. The changes in the two-dimensional gel pattern cannot be explained merely by alteration in the charge of the polypeptides, as their appearance is also detectable on one-dimensional SDS gels. However, we cannot exclude the possibility of very rapid degradation of the polypeptides in the egg but not at the two-cell stage. Physical sequestration of the corresponding mRNAs could also explain the results, but the basis for such masking is presently unclear. Only a few polypeptides are involved, and their close proximity on two-dimensional gels suggests that they may be structurally related and under co-ordinate control. It seems that the developing embryo requires large amounts of these proteins at a time when a sudden burst of transcription is inconvenient or impossible, and therefore relies on a post-transcriptional control mechanism. In contrast, development beyond the two-cell stage seems to require some transcription of the embryonic genome (Table 1)[13].

We thank Martin Johnson, Gil Schultz, Tim Hunt and Hester Pratt for discussions. This work was supported by grants from the Ford Foundation and the MRC to Dr M. H. Johnson.

Myosin isoenzyme redistribution in chronic heart overload

Anne-Marie Lompre, Ketty Schwartz, Anne d'Albis*, Gabrielle Lacombe, Nguyen Van Thiem & Bernard Swynghedauw

U127 INSERM, Hôpital Lariboisière, 41 Boulevard de la Chapelle, 75010 Paris, France

Since the first observation by Spann *et al.*[1], it has become clear that in cardiac hypertrophy induced by a mechanical overloading, the velocity of shortening of the cardiac muscle (V_{max}) is reduced (see ref. 2 for review). Most authors agree that this mechanical alteration is accompanied by a decrease in the Ca^{2+}-dependent ATPase activity of myosin (see ref. 3 for review). The molecular basis of such changes was unknown because the structural modifications of the myosin molecule were ill-defined[4–6]. Nevertheless, it has recently been shown that, like skeletal muscle myosin[7], cardiac myosin is composed of several polymorphic forms, comparable to isoenzymes[8,9]. In the skeletal muscle, new functional requirements can induce changes in both contractile activity and type of myosin isoenzyme synthesised[10–13]. We now report that an increase in cardiac work produced by mechanical overloading in rats induces the preferential synthesis of a cardiac myosin isoenzyme characterised by specific immunological and electrophoretic properties and exhibiting a lower ATPase activity. This adaptive change could account for the reduced shortening speed of this hypertrophied cardiac muscle.

Cardiac hypertrophy was induced in male Wistar rats (200 g, Animalabo) either by a volume[14] or pressure overload[15], or by combining both procedures[14], that is, abdominal aorta constriction and induction of aortic incompetence 2 weeks later (see Table 1 legend). Animals exhibiting 60 to 100% cardiac hypertrophy by any of the above procedures were selected for this study, but it should be pointed out that the most reproducible results were obtained with the two-step procedure. Enzymatic, immunological and electrophoretic tests were performed on myosins from the same hypertrophied hearts and from hearts of sham-operated animals.

Steady-state Ca^{2+}- or Mg^{2+}-dependent ATPase activities of myosins from hypertrophied hearts were both significantly depressed, whereas the K^+-activated ATPase remained unchanged (Table 1). This is in full agreement with earlier observations in rats[16,17] and in other animal species[4,18–20]. Since it has often been suggested that this diminished Ca^{2+}-dependent activity might be due to artifactual denaturation, the functional integrity of individual myosin preparations was assessed by measuring their early phosphate burst size, that is the number of ATP moles cleaved per myosin molecule. As shown in Table 1, the myosins extracted from both hypertrophied and normal hearts cleaved 0.8 mol of ATP per active site. This value, in close agreement with previously published results for normal skeletal and cardiac muscles[23–25], rules out the possible presence of denatured, aggregated or oxidised molecules[23,25]. Such absence is consistent with the functional integrity of the site known as SH1 in the hypertrophied rabbit myocardium[20]. In addition, electrophoresis on SDS-polyacrylamide gels visualised the heavy subunits as single bands (not shown) indicating that the degraded components observed by others in dogs[6] were not present in our preparations. The decrease in ATPase specific activity was therefore not due to molecular denaturation, but more likely indicated the presence of a new myosin species with different enzymatic activities.

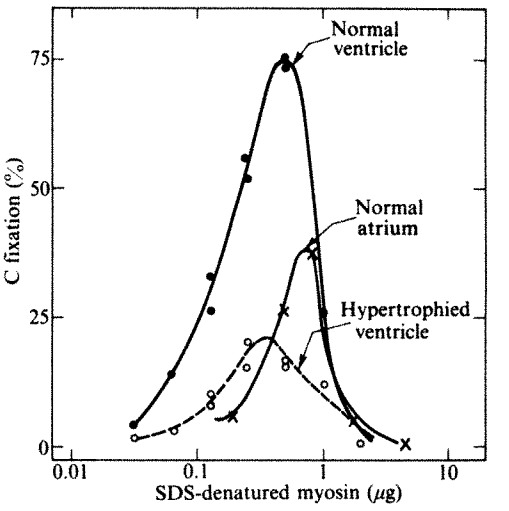

Fig. 1 Microcomplement fixations with antiserum 47-3-70 to normal rat ventricular SDS-heavy meromyosin. Antiserum dilution 1:5,250. SDS-denatured myosins were obtained from the ventricles and atria of sham-operated animals and the ventricles of a hypertrophied rat heart (100% hypertrophy preparation no. 5 in Table 1). Antibodies were raised in guinea pigs against purified rat ventricular heavy meromyosin[28], denatured by heating for 5 min at 90 °C in the presence of SDS (5 mg per mg protein), 2% 2-mercaptoethanol, 50 mM NaCl and 100 mM Tris-HCl, *p*H 7.6. Excess SDS was removed immediately before immunisation by gel filtration on a 2 × 15 cm Sephadex G-10 column[27]. Microcomplement fixations were produced according to Levine[26], in a final volume of 0.7 ml. Before the assays, myosins were denatured and excess SDS was removed as described above. The mean difference between two controls was equal to 4.8%, s.e.m. = 1.7, $n = 7$. These antibodies are specific to a denatured configuration of heavy-meromyosin and myosin induced by treatment with either guanidine or SDS[27] and, as shown here, can easily discriminate between atrial and ventricular myosin isoenzymes.

This possibility was first tested by an immunochemical approach, using micro-complement fixation (MCF), a technique known for its ability to detect small structural changes[26]. Antibodies specific to a denatured structure of rat ventricular myosin were obtained by injecting guinea pigs with heavy meromyosin denatured by SDS treatment[27]. SDS-denatured myosin from each hypertrophied heart was made to react with antisera from two different animals. There was a vertical shift in the maximum amount of complement fixed (15–35%), compared to the controls (50–70%) (Fig. 1). The immunological distances between normal and hypertrophied heart myosins were calculated by using several dilutions of antisera for the reactions[29]. Distances were between 10 and 30, the maximum value corresponding to the myosin with the lowest enzymatic

Table 1 Enzymatic analysis of myosins from normal and sham-operated rat hearts (S) and hypertrophied hearts (H)

Type of overloading, interval between surgery and killing (% of heart hypertrophy)	Burst size (mol ATP per myosin site)		Specific activity in steady state (nmol P_i mg^{-1} min^{-1})					
			Ca^{2+}-activated		Mg^{2+}-activated		K^+-activated	
	S	H	S	H	S	H	S	H
(1) Aortic incompetence, 130 days (60%)	0.85	0.80	1,210	760	—	18	610	540
(2) Aortic incompetence, 141 days (93%)	0.85	0.85	1,180	860	37	27	660	690
(3) Aortic stenosis, 35 days (100%)	0.75	0.70	1,190	880	43	31	620	720
(4) Aortic stenosis, 10 days, +incompetence 92 days (90%)	0.85	0.80	1,020	730	27	18	620	760
(5) Aortic stenosis, 10 days, + incompetence 63 days (97%)	—	—	980	540	29	12	710	750

50% abdominal aorta constriction was obtained using the method of Cutilletta *et al.*[15]. Aortic incompetence was produced by forcing a stiff polyethylene catheter (no. 3 to 4 Biotrol) through the left carotid and then the aortic cusps. At various times after surgery, rats were killed by a blow on the head and hearts were rapidly excised. Ventricles were detached from the atria and bases of the great vessels, weighed (Vw) and frozen in liquid nitrogen within 2 min. For each animal, theoretical ventricular weight (Thw) was calculated according to the following regression curve, established in 152 controls: Thw (g) = $[(2.02 \times \text{body wt}) + 197] \times 10^{-3}$. The per cent hypertrophy was equal to $(Vw - Thw) \times 100/Thw$. Myosin was prepared essentially according to Offer *et al.*[21], except that ammonium sulphate fractionation was performed in the presence of 100 mM sodium pyrophosphate, 4 mM ATP and 2 mM dithiothreitol *p*H 7.0. The A_{280}/A_{260} ratio was between 1.4 and 1.6. Early phosphate burst size was determined manually by a slightly modified version of the method of Taylor and Weeds[23], in stoichiometric conditions[24], in which 10 μM myosin site (5 μM myosin) and 10 μM radioactive ATP were mixed at 22 °C, in a medium consisting of 0.5 M KCl, 50 mM Tris-HCl, 5 mM $MgCl_2$ and 0.1 mM dithiothreitol, *p*H 7.4. Steady state activities were measured at 25 °C in the presence of 2.5 mM ATP, 50 mM Tris-HCl, *p*H 7.5 and either 5 mM $CaCl_2$, 5 mM $MgCl_2$ or 1 M KCl and 5 mM EDTA. Inorganic phosphate was determined colorimetrically with malachite green[22].

activity. The present results confirm and extend our recent observation of an antigenic difference between native myosins from normal and hypertrophied rat hearts[17]. It is thus unlikely that such immunological changes reflect conformational changes only. Indeed numerous observations have shown that vertical shifts of the micro-complement fixation curves indicate amino acid substitutions[29].

Finally, the presence of different myosin isoenzymes in the normal and hypertrophic hearts was screened by electrophoresis of the native proteins in a non-dissociating medium. We used this technique according either to Hoh *et al.*[9], or to a modified version of a previously described method[30,31]. In agreement with the findings of Hoh *et al.*[9], we observed in a highly reproducible manner three isoenzymes V_1, V_2 and V_3 (Fig. 2) in normal adult rat ventricles. V_1 had the highest mobility and was predominant in both right and left ventricles. The electrophoretic pattern was different in the ventricles from hyperthrophied hearts (Fig. 2); making the reasonable assumption that the three isoenzymes were the same as in the normal hearts, a redistribution of V_1, V_2 and V_3 was found, with a predominance of V_3 in the largest and an intermediary pattern in the less affected hearts. Furthermore, the isoenzymic shift was more pronounced in the left ventricle (not shown) which is more affected in our experimental model. According to Hoh *et al.*[9] and to our unpublished results, the specific ATPase activity of V_3 is lower than that of V_1; the increase in V_3 may therefore account for the drop in overall enzymatic activity (Table 1). These findings are consistent with the isoenzymic switches already reported between V_1 and V_3 (ref. 9). As in our model of hypertrophy, hypophysectomy induces an increase in V_3 and a fall in myosin ATPase activity,

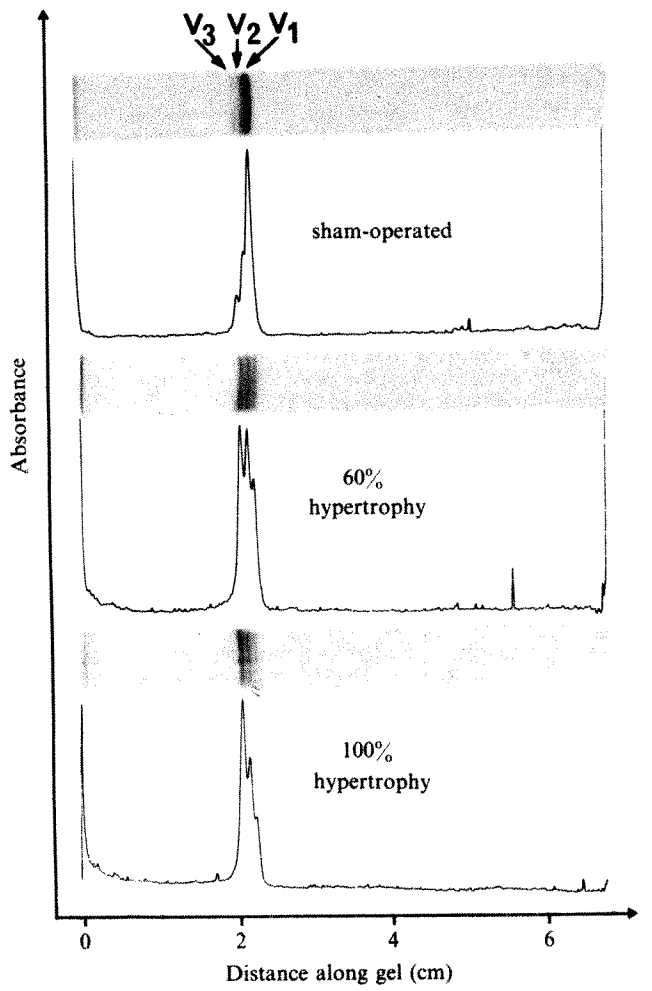

Fig. 2 Typical electrophoretic patterns and densitometric profiles for native myosins from ventricles of one normal (sham-operated) and two hypertrophied hearts (60 and 100% hypertrophy respectively). Myosin samples (1 to 3 μg) were run for 16 h on cylindrical gels (60 × 5 mm), 3.88% in acrylamide and 0.12% in *N-N'*-methylene bis-acrylamide at 14 V cm^{-1} and 2 °C, in 20 mM sodium pyrophosphate (*p*H 8.8) in the presence of 10% glycerol[9]. V_1, V_2 and V_3 correspond to the three components described by Hoh *et al.*[9]. Identical patterns were observed when crude tissue extracts, prepared either with Guba-Straub's buffer or according to Hoh *et al.* where run instead of purified myosins. When run on a second pyrophosphate gel, the main isoenzyme, V_1 in the normal heart and V_3 in the hypertrophied one, migrated as a single band. The electrophoretic pattern was independant of the acrylamide concentration (2.8 to 4%). The same results were obtained in a slightly different medium consisting of 40 mM sodium pyrophosphate (*p*H 8.5), 1 mM EDTA and 0.01% 2-mercaptoethanol as described by d'Albis *et al.*[31].

whereas subsequent thyroxine treatment produces both an increase of V_1 and a rise in the enzymatic activity.

It is now accepted that there is a close correlation in different types of skeletal muscles[32] and in hearts of different animal species[33] between contractile element shortening capacity and myosin ATPase. Since the velocity of shortening of the cardiac muscle is reduced in gross cardiac hypertrophy induced by a mechanical overload (reviewed in ref. 2), the predominance we demonstrate in this muscle of a myosin isoenzyme of lower activity is not surprising. On the contrary thyroid hormone increases cardiac performance and more especially V_{max} (reviewed in ref. 34) and induces in hypophysectomised rats[9] as well as in euthyroid rabbits[35], the synthesis of an isoenzyme of higher enzymatic activity. All these findings suggest that contractile activity of the diseased myocardium is controlled as in normal skeletal and cardiac muscles[32,33], by the rate of hydrolysis of ATP by its myosin isoenzyme. In addition, adaptation in cardiac performance seems to be mediated by a change in myosin species, a process which can be related to the adaptive responses of the skeletal muscles to new functional requirements[10–13]. The normal peak active isometric tension observed in cardiac muscles after a pressure overload[36] suggests that such hypertrophied muscles, in spite of their contractile defect, work with normal efficiency. Similarly, slow skeletal muscles work more efficiently when contracting at slow speeds, compared to fast muscles, and this characteristic also seems to be connected with decreased ATPase activity[37]. The molecular basis of adaptation in cardiac performance we describe could therefore account for the compensatory step observed in chronic heart overload. It might be also hypothesised that cardiac insufficiency occurs when the adaptive change has reached its limit, that is, when the isoenzymic shift is a maximum.

Three-dimensional structure of hyper-modified nucleoside Q located in the wobbling position of tRNA

Shigeyuki Yokoyama*, Tatsuo Miyazawa*, Yoichi Iitaka†, Ziro Yamaizumi‡, Hiroshi Kasai‡ & Susumu Nishimura‡

* Department of Biophysics and Biochemistry, Faculty of Science, University of Tokyo

The hyper-modified nucleoside Q (queuosine) is exclusively located in the wobbling position of anticodons of $tRNA^{Tyr}$, $tRNA^{His}$, $tRNA^{Asn}$ and $tRNA^{Asp}$ that recognise codons NA^{U}_{C} (ref. 1). Queuosine and its hexose-containing derivatives[2,3] are widely distributed in microorganisms, animals and plants[4,5]. We confirm here the chemical structure of queuosine as 7-(3, 4-*trans*-4, 5-*cis*-dihydroxy-1-cyclopenten-3-ylaminomethyl)-7-deazaguanosine[2,6] (Fig. 1). The unique structural features of Q are the unusual cyclopentenediol side chain and the 7-deazaguanine ring. Queuosine is one of the most complicated modified nucleosides found thus far[7].

For elucidating the biological significance of this complicated modification, it is important to determine the conformation of the Q unit in the tertiary structure of tRNAs: is the conformation of the anticodon loop very different from that of usual tRNAs, such as yeast $tRNA^{Phe}$ (refs 8–10), because of the existence of the bulky side group? Does the side chain approach the anticodon–codon interaction site and thus influence the codon recognition properties? Is the side chain buried in the anticodon loop, or exposed enough to be recognised by another molecule? To answer these questions, we first determined the three-dimensional structure of queuosine 5′-monophosphate (pQ) by X-ray crystallography. We then incorporated this conformation of Q into the anticodon of tRNA, on the basis of the

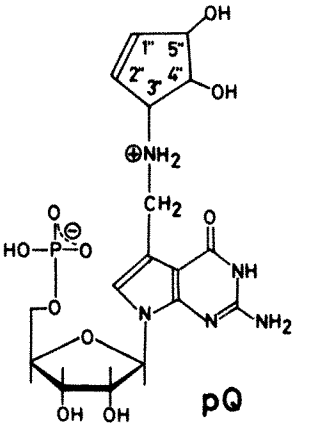

Fig. 1 Structural formula of pQ. Crystal data: 7-(3, 4-*trans*-4, 5 - *cis* - dihydroxy - 1 - cyclopenten - 3- ylaminomethyl) - 7 - deazaguanosine 5′-monophosphate (queuosine 5′-monophosphate, pQ), $C_{17}H_{14}D_{10}N_5O_{10}P \cdot 7/2D_2O$, $FW = 569$, orthorhombic, space group $P2_12_12_1$, $Z = 8$, $Dx = 1.528\ gcm^{-3}$, $a = 26.895(5)$, $b = 7.707(2)$, $c = 23.883\ (10)$ Å, $V = 4{,}951$ Å^3

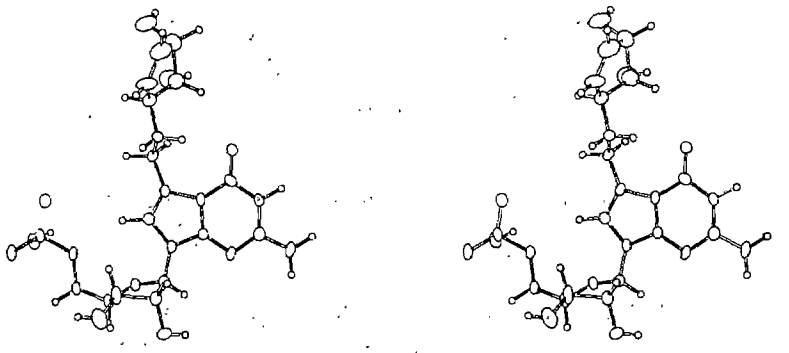

Fig. 2 Stereo view of pQ (molecule I) in crystalline form.

coordinates of yeast $tRNA^{Phe}$ (ref. 11), as done previously for some other modified nucleosides[12–14]. The results indicate that the bulky 7-substituent group of Q takes the planar *trans* conformation and is fully extended outwards, so that it does not interfere with codon–anticodon interaction. Thus it seems possible that the cyclopentenediol side chain of Q may interact with other molecules in some process other than protein biosynthesis.

Queuosine 5′-monophosphate was isolated from a nuclease P_1 digest of *Escherichia coli* tRNA by Dowex 1 column chromatography[15]. pQ in the free acid form was crystallised from concentrated D_2O solution (pD, 4.5), so that the phosphate group was monoanionic and the aminomethyl group at position 7 of the 7-deazaguanine ring was positively charged. A small fragment of $0.3\times0.08\times1.5$ mm was cut from a large crystal of $0.3\times0.08\times3$ mm and sealed in a thin-walled glass capillary to prevent loss of water of crystallisation. The specimen was mounted on a Philips four-circle diffractometer and the unit cell dimensions and intensity data were measured with monochromated CuKα radiations using a graphite plate. The crystal data are given in Fig. 1 legend. The intensities were measured within a 2θ range of 6–120° by the θ–2θ scan method. A total of 5,589 reflections were measured as above the $I>2\sigma(I)$ level, including 965 symmetry equivalent reflections ($\bar{h}kl$ versus hkl). Deterioration of the crystal was monitored by measuring the intensities of three standard reflections. The sums of the three intensity values measured at the beginning and at the end of the measurement showed only a slight decrease (1.4%) throughout the period of measurement.

The crystal structure was solved by the direct method based on the procedure using MULTAN[16]. An E map calculated for the most probable set gave a plausible arrangement of peaks for phosphate groups. The whole structure was established by successive use of difference Fourier and least-squares methods. At the final stage of the refinement, water oxygen atoms were located on the difference electron density map. Four water molecules were found to occupy several sites. Their positions were assigned so that each of the four water oxygen atoms occupy with a half occupancy factor at the two separate positions not far more than 2 Å. A block-diagonal least-squared refinement for 693 parameters of 77 atoms yielded an R factor of 0.117 for 4,624 observed reflections. Hydrogen atoms were not included in the refinement but they were located by model building.

The present study confirms the chemical structure of queuosine reported earlier[2,6]. The geometries of the phosphate and imino groups indicated that the phosphate group bears one negative charge and the imino group in the side chain is protonated. Thus the molecule takes the dipolar form. The absolute configuration was determined assuming that the ribose group takes the D-configuration. It was then confirmed that the absolute configuration at C(3″) of the cyclopentene ring is the same as that determined by synthetic and CD and ORD studies[17]. There are two crystallographically independent molecules (I and II), which have quite similar molecular structures; the r.m.s. differences between the two molecules are 0.032 Å and 1.6° for bond lengths and bond angles, respectively, and the dihedral angles are nearly equal, being within 7° of each other. The bond lengths and bond angles of the pyrimidine moiety of the 7-deazaguanine ring are almost equal to those of the unmodified guanine ring[18]. It is likely, therefore, that the hydrogen-bonding or base-pairing properties of the Q base (queuine) are little influenced by replacement of the nitrogen atom by a carbon atom at position 7. The ribose ring takes the C(3′)-endo form, with the exocyclic C(4′)—C(5′)—O(5′) bond in the g^+-t form ($\psi=52°$ and 52° and $\phi=-171°$ and −174°, for molecules I and II, respectively) and the glycosyl bond in the anti form ($\chi=27°$ and 30°, respectively). The side chain at position 7 of the 7-deazaguanine ring is fully extended; C(7)—CH_2—NH_2^+—C(3″)—C(2″) takes the planar *trans* conformation. An intramolecular hydrogen bond is formed between the protonated imino group and O(6) of the 7-deazaguanine ring. The dihedral angle of C(8)—C(7)—CH_2—NH_2^+ is expected to be about 90°, as is commonly observed in related structures having a methylenic chain linked to the planar ring system. Actually however, this dihedral angle of pQ is twisted to as much as about 120°, possibly by formation of a rather strong intramolecular hydrogen bond NH_2^+ ... O(6). The bulky 7-substituent group is extended (Fig. 2), but not towards the hydrogen bonding moiety of the Q base

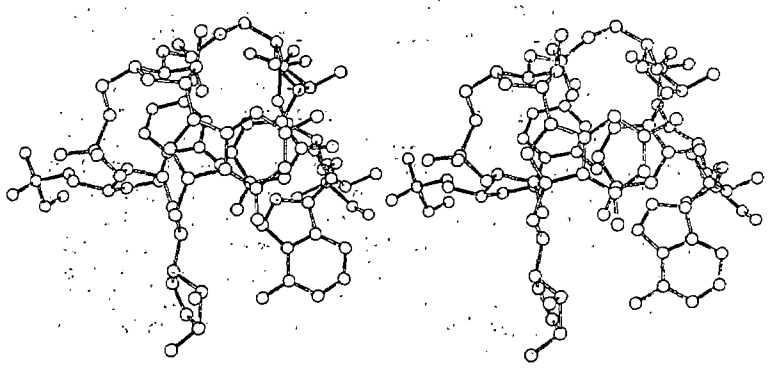

Fig. 3 Stereo view of U-Q-U-A, as constructed from the atomic coordinates of pQ (the present study) and yeast $tRNA^{Phe}$ (ref. 11).

and the third letter of the codon (C or U). This also indicates, in accord with biochemical observations, that the codon recognition properties of Q are not significantly different from those of G (ref. 1 and S. Noguchi and S.N., unpublished). The cyclopentene ring is puckered; C(3″)—C(2″)=C(1″)—C(5″) is coplanar but C(4″) is displaced by 0.5 Å from this plane on the same side as the NH_2^+ group, possibly due to the existence of a diol {O(4″)H and O(5″)H} in the *cis* configuration. This puckered form is stabilised by the equatorial orientation of the large substituent (NH_2^+—CH_2—···).

The atomic coordinates of yeast $tRNA^{Phe}$ (ref. 11) were used for the model-building study on the spatial arrangement of the modified nucleoside Q in the anticodon loop of tRNA. The first letter of the anticodon, Gm(34), was replaced by Q with the conformation found in the present study on the crystal of pQ. The second letter of the anticodon, adenine(35), was replaced by uracil, but the third letter, adenine(36), was retained. This sequence QUA corresponds to that in the anticodon of the $tRNA^{Tyr}$ of *E. coli*. Figure 3 shows a stereoscopic view of the three-dimensional structure involving U(33)—Q(34)—U(35)—A(36). It may be seen that Q is now incorporated into the first position of the anticodon without any steric repulsion from other parts of the anticodon loop. The cyclopentenediol group of Q is exposed out of the anticodon, in contrast to the short group of 2-thiouridine derivatives, which is more or less buried in the anticodon loop[13,14].

In addition to the intra-unit hydrogen bond with O(6), the NH_2^+ group of Q may also be involved in a hydrogen bonding interaction with ribose O(2′) of the preceding U(33); the distance between the imino nitrogen and ribose oxygen is as short as 3 Å and N—H···O is nearly linear. The side group of Q(34) is thus fixed by these two hydrogen bonds, and the *cis*-diol group is orientated out to the open space, away from the base-pairing moiety of the anticodon.

The biochemical function of Q in protein biosynthesis is not yet understood. Q has a wobbling property not significantly different from that of G. Extensive studies on the properties of $tRNA^{Tyr}$ containing G in place of Q, isolated from Q-deficient mutants of *E. coli* have not revealed any differences between Q and G with respect to binding of $tRNA^{Tyr}$ to ribosomes or aminoacylation (S. Noguchi and S. N., unpublished). Two species of rabbit reticulocyte $tRNA^{His}$ containing either Q or G were used with equal efficiency in haemoglobin biosynthesis[19]. These observations are consistent with the conformation of Q found in the present study by X-ray diffraction analysis. This hypermodified nucleoside Q is widely found in tRNAs of various organisms and thus is expected to be essential for some biological process other than protein biosynthesis. Q in *Drosophila* tRNA is suggested to have a role in cell differentiation or expression of a particular enzymatic activity[5,20]. In tumour cells, under-modified tRNA containing guanosine in place of Q appears specifically[21].

In conclusion, the conformational characteristics of the modified nucleoside Q appear to bring the cyclopentenediol group out of the anticodon loop, where it does not interfere with recognition of the codon of mRNA. This bulky side chain with its unique structure, charge and reactive group constitutes a suitable site for specific interaction with protein or other components. Thus the exposed cyclopentene ring (and orientation of the *cis*-diol group) of Q is possibly important for some biochemical function of tRNA other than protein biosynthesis.

Antiparallel and parallel β-strands differ in amino acid residue preferences

Shneior Lifson & Christian Sander

Chemical Physics Department, Weizmann Institute of Science, Rehovot, Israel
and
Institut für Theoretische Physik, Heidelberg, FRG

A β-strand is a particular type of extended sequence of amino acid residues, an element of secondary structure of proteins. β-sheets are an assembly of strands, often bringing together parts of the protein which are separated along the backbone. As such, β-sheets are an element of tertiary structure. Parallel (β_P) and antiparallel (β_A) arrangements of strands in a sheet differ in the hydrogen bond pattern between strands, as shown schematically in Fig. 1, and in the type of chain connectivity they allow: short reverse turn connections for β_A and longer crossover connections for β_P (refs 1–3). Most present secondary structure prediction methods (for reviews refs 4–6) use a four-state distinction of secondary structure: α-helix, β-strand or extended, reverse turn, and 'random coil' (everything else). With a data base of 30–40 different protein structures, the conformational preferences for all amino acid residues in these four states seem to have converged[7]. However, the steadily increasing data base of structurally known proteins makes a refinement of the four-state description feasible. Although more refined classifications of conformational states based on finer subdivisions of (φ, ψ)-space have been made[8,9], we prefer making distinctions based on structural environment. Using a novel definition of β-sheet structure in terms of the tertiary structure juxtaposition of strands, we have analysed residue contacts in known β-sheets and report here secondary structure preferences for the 20 amino acids, separately for antiparallel and parallel arrangements of strands. The distinction between the two arrangements results in strikingly different and sharpened sets of preference parameters, including some of the largest values reported so far for any substructure. These results point the way towards a basic improvement of secondary structure predictions by further distinction of secondary structure elements according to tertiary structure environment. Beyond secondary structure prediction, the different preferences for β_A and β_P may aid in predicting the tertiary interaction between strands.

Our independent compilation of β_A- and β_P-residues in 30 proteins (a list of the proteins is given in ref. 10) defines β-sheets by their strand–strand interactions, rather than by single residue conformation, such as backbone (φ, ψ) angles. The protein coordinates are from ref. 11 (and updates as of August 1978). We identify two neighbouring antiparallel (or parallel) stretches of polypeptide chain (at least three residues each) as a pair of β_A (or β_P) strands (1) if pairs (i, j) of contacting residues have their side groups on the same side of the sheet (Fig. 1), and (2) if the C=O and N—H groups of the backbone are properly orientated[10]. Single strands are not counted. For regular stretches of

The order of amino acids reflects their average structural similarity[17]. Amino acids which are observed to be more mutually exchangeable in evolution are nearer each other in this list.

* Numbers taken from ref. 11.

† The preference for $\beta_A(\beta_P)$ is a normalised frequency: the frequency in $\beta_A(\beta_P)$ divided by the global frequency. Note that the definitions of β-residues vary among different authors[7,13,15]. Furthermore, our preferences are for making β-sheet contacts, whereas those of the other authors are for occurrence in extended or β-strands.

β-strands (generally away from the edges of sheets) our identification of β-residues agrees with that of the crystallographers. As we define β-residues by their contact with neighbouring strands, we count residue contacts rather than residues in deriving the single residue frequencies. Thus, residues in strands at the edge of a sheet are counted once, residues in interior strands are counted twice, and residues making β_A contact on one side and β_P on the other are counted once for each type of contact.

The residue contact counts and residue contact frequencies are given in Table 1. β_A structures outweigh β_P by about three to one in the data base. The amino acid compositions of β_A and β_P are remarkably distinct. About one-third of all residue contacts in β_P are made by Val and Ile, the two non-polar side chains branched at C_β. Val (21%), Ile (12%), Leu (10%) and Ala (8%), with purely aliphatic side chains, together account for more than 50% of all contacts in β_P. In β_A six amino acids are needed to reach the 50% mark, including the polar side chains Thr and Ser, and the order of abundance (listed in decreasing order) is different: Val, Leu, Thr, Ser, Ala, Ile.

The 'conformational preference' parameters presented in Table 1 are defined as the ratios between the frequency of pair-contacts made by a residue in β-strands and the global frequency of occurrence of that residue anywhere. Values larger than 1.0 indicate preference of the particular residue for $\beta_A(\beta_P)$, values less than 1.0 indicate the opposite. Conformational preference parameters (derived from residue frequencies rather than from contact frequencies) have been used by many authors (for reviews see refs 4–6, 12) in the prediction of secondary structure (called 'potential', 'propensity', 'information measure'). The parameters given by Chou and Fasman[13], by Garnier *et al.*[14], and by Levitt[12] are included in Table 1 for comparison. There is overall agreement between the 'all β' (β_A and β_P together) preferences in the different studies. The differences, for example, for Pro, Glu or Trp, arise because the studies use not only different sets of proteins as their data base, but also different ways of identifying β-residues[7,13,15] and, in our case, different weights for interior and edge strands.

Comparison of conformational preferences between β_A (antiparallel) and β_P (parallel) shows: (1) the β_P structure is more selective: there are more extreme large and small values in β_P (standard deviation 0.66 for β_P but only 0.40 for β_A; high and low: 2.63 and 0.28 for β_P but only 1.75 and 0.42 for β_A), and, in β_P fewer residues are preferred (only 6, compared with 12 in β_A) and for these few the preference is stronger (except Tyr). In fact, the 20 amino acids can be divided into three groups (Table

Table 2 Conformational classification of β-sheet residues

		Conformational preference
Favourable in both β_A and β_P	Val Ile Met Leu Phe Tyr	>1.0 in β_A and β_P
Favourable in β_A but unfavourable in β_P	Gln Thr Arg His Cys Trp	>1.0 in β_A and <1.0 in β_P
Unfavourable in both β_A and β_P	Gly Pro Asp Glu Ala Asn Ser Lys	≤1.0 in β_A and β_P
Best sheet 'makers' in β_A	Trp > Tyr > Val > Ile	>1.5
Best sheet 'makers' in β_P	Val > Ile > Met	>1.5
Worst sheet 'breakers' in β_A	Pro < Asp < Gly < Glu < Asn	≤1/1.5
Worst sheet 'breakers' in β_P	Gln < Pro < His < Asp < Glu < Thr < Lys	≤1/1.5

2)—favourable in both β_P and β_A, favourable in β_A but not in β_P, and unfavourable in both β_A and β_P. (2) β_P 'abhors' polar and charged groups and favours hydrophobic side chains more strongly than β_A: only the purely hydrophobic residues Val, Ile, Leu, Met, Phe are significantly preferred (>1.2) in β_P, whereas in β_A also Thr, Cys, Tyr and Trp, all containing polar atoms, show values above 1.2. (3) Val and Ile are particularly favoured in β_P, with the second largest secondary structure enhancement values reported so far—2.6. Only the value for Pro at the second position in reverse turns[16] is larger—3.4. In β_A the preferences for Tyr and Trp (1.7) are exceptionally large. Note that both have a large non-polar ring in combination with a polar group. (4) The differences between β_A and β_P are particularly large for Gln, Thr, His and Trp (favourable in β_A and unfavourable in β_P); Gln is less favoured in β_P by about a factor of 4.

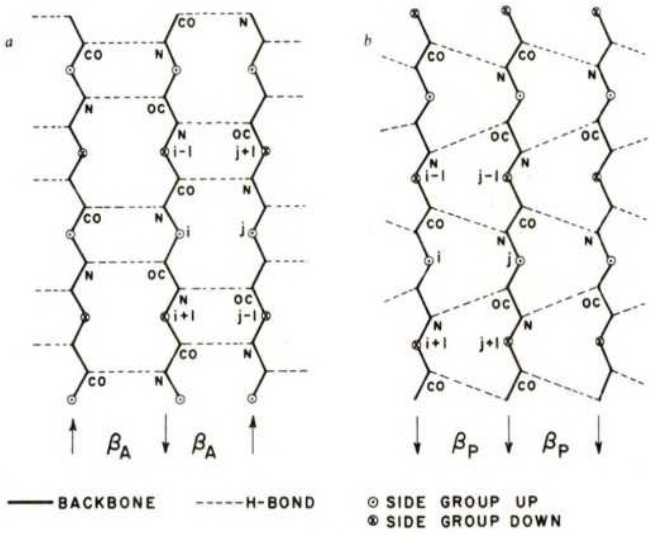

Fig. 1 A schematic drawing of antiparallel (*a*) and parallel (*b*) β-strands. The arrows indicate the N-terminal to C-terminal direction of the polypeptide backbone. Although the (ϕ, ψ) backbone angles are similar for β_A and β_P, the arrangement of the strands and the hydrogen-bonding patterns are fundamentally different. This difference is also reflected in different amino acid preferences.

The results presented here are potentially useful in two ways. On the one hand, they help to pose more specific questions, by focusing attention on those residues which have a special structural role. In this, residues which are both abundant and preferred are the most interesting. For example, one may ask: can Val and Ile serve as nucleation points for β_P-strands by restricting the backbone conformation with their side chains? Do they pack particularly well in the environment of the crossover connection between β_P-strands? Do they interact preferably with each other in forming clusters on the surface of β-sheets? The aim in investigating this type of question is to understand the physical basis of the statistical preferences.

On the other hand, the conformational preferences can be incorporated into structure prediction schemes, allowing distinct predictions for antiparallel and parallel β-stands. However, when this is done the limitations inherent in all statistical approaches to protein structure must be kept in mind: proteins are biologically evolved molecules with a particular structure tailored to a particular function. Only average properties of protein structures can be understood by statistical methods, but not the highly individual character of each protein.

Thus, the main conclusions regarding protein architecture are: (1) antiparallel and parallel β-strands are as distinct in their amino acid preferences as are α-helices and β-strands; (2) parallel β-strands impose much more severe constraints on their amino acid content than antiparallel β-strands or α-helices; (3) Val and Ile have an outstanding role in parallel strands. In a related paper[10], we analyse interstrand pair recognition of amino acid residues and its role in the tertiary structure assembly of strands into sheets.

As more protein structure data become available, further distinctions of secondary structure elements according to the type of tertiary contacts should be made. For example, one can distinguish different hydrogen-bonding positions in β-sheets, solvent-exposed and interior faces of sheets or helices, segments in tertiary contact with sheets compared with those in contact with helices. Such distinctions are likely to lead to more clearcut statistical preferences, and also serve as a starting point for predicting tertiary structure.

We thank John Moult, Barry Robson, Charlotte Schellmann and Joel Sussman for critical suggestions and Richard Feldman for supplying protein coordinates.

matters arising

Evidence for a higher natural uranium content in world rivers

THE letter by Mangini *et al.*[1] on aspects of the geochemical cycle of uranium requires comment. They attempt to show that phosphatic fertilisers do not contribute significantly to the uranium budget of rivers or groundwater, but the arguments and evidence they produce to support this claim are deficient.

They claim, from the observed phenomenon that rivers show a significant ^{234}U excess but that phosphate fertilisers do not, a contradiction to the assumption of a pollution effect. Yet the ^{234}U excess merely reflects the preferential leaching of this daughter product rather than its parent ^{238}U. Since this fractionation was noted in 1953[2] it has been developed as a uranium exploration tool[3] and a dynamic equilibrium model[4] has been developed showing its variation about source rocks which themselves have an average AU ~ 1 (AU, ratio of ^{234}U to ^{238}U).

A similar claim is made that the close relationship found by my colleagues between uranium content and bicarbonate (HCO_3^-) content[5] for rivers and groundwaters indicates a natural origin for the uranium. Again, this relationship merely shows the common mode of migration of uranium in solution as a bicarbonate complex and gives no evidence for the source of the uranium.

The lack of a clearcut relationship between the uranium and phosphate contents of the water is further taken as evidence for a negligible contribution of uranium from phosphatic fertilisers. Again this is a function of the relative solubilities of the uranium and phosphate components and itself provides no evidence for the source of the uranium. In the Devonian sediments of northern Scotland there are naturally occurring bedded concentrations of uranium in phosphatic rocks[6,7] and related uranium anomalies are present in the surface water, but these exhibit no corresponding anomalies in phosphate content. There is thus selective leaching of uranium from these bedded phosphatic sediments.

Additionally, both in the Caithness and Orkney areas a limited number of spuriously high values were detected (>10 to 100 $\mu g\ l^{-1}$ U) and these were related to transient enrichments from fertilised areas. Samples of phosphate fertilisers used in the area contain up to 100 μg U per g. This was taken as supportive evidence for the regional scale contamination noted by Spalding and Sackett[8], but rejected by Mangini *et al.*[1].

Rock phosphate (apatite/collophane) is able to fix uranium in both oxidising and reducing conditions. Uranium can be present both in the U^{4+} form, replacing Ca^{2+} in the apatite structure, and as U^{6+} where it is adsorbed on the surface. It is the adsorbed uranium which is readily removed by surface waters. Experimentally Spalding and Sackett[8] showed the ease with which uranium may be leached by water from superphosphate fertiliser. They also demonstrated that after application of fertiliser and 0.5 inches of rainfall equivalent, the uranium level in the run-off was 28 times greater than in a similar blank experiment.

Mangini *et al.*[1] present groundwater evidence from a highly fertilised area which does not show any enhancement of uranium in the subsurface waters and take this to indicate that "more than 95% (2σ) of uranium supplied with the fertilisers is retained in the uppermost soil layers". They also note that "less than 0.01% of the phosphate goes into groundwater" [I presume ND in their Table 1 means 'not detectable' and not 'not determined' as stated] and state "assuming a similar transport mechanism for uranium the contamination would make less than 0.004 $\mu g\ l^{-1}$". As indicated in the preceding paragraphs this assumption must be rejected as uranium is leached separately from the phosphate.

The explanation for the low uranium values in the groundwater, although the added fertiliser contains 50 p.p.m. U, may simply be that the uranium is adsorbed and complexed from the groundwater in the soil profile but could still be being leached by the surface run-off. No figures for uranium in the surface run-off are presented and, as the area has been fertilised for several decades, the original background may not be determinable. A transient increase following application of fertiliser should be sought.

MANGINI REPLIES—Our conclusion that in the Handschusheimer Feld area the influence of uranium from phosphate fertilisers is small was derived both from the low uranium contents of groundwater and river water, more importantly, from their high AU (~1.6).

We appreciate the opportunity to clarify a point to those not familiar with ^{234}U and activity ratios (AU). ^{234}U is a member of the ^{238}U decay series, with a half life of 244,000 yr. Disequilibrium between ^{234}U and ^{238}U ($AU \neq 1$) is a common phenomenon in nature. Rocks and clays from which uranium is being extracted have $AU \leq 1$, rivers and groundwaters $AU > 1$ (average 1.20) and recent uranium deposits (younger than 10^6 yr) $AU \geq 1$. In uranium-enriched phosphate fertilisers we find, as expected, AU ~ 1.

Preferential selective leaching of ^{234}U from rocks and clays is attributed to the α-recoil on the ^{234}Th nucleus, following the ^{238}U α-decay. Recoil energies of approximately 0.1 MeV 'shoot' ^{234}Th (the short-lived grandmother of ^{234}U) from a 550-Å thick surface layer of the mineral grains into solution[1]. Whenever traces of uranium are leached, the solution will have $AU \geq 1$.

The situation is different in the upper soil layers, where uranium is being supplied by fertilisation at AU ~ 1.

In fact a competitive fertiliser should nearly completely dissolve in a period of months. The consequence is that nearly all uranium (^{234}U and ^{238}U) undergoes dissolution (as confirmed by Spalding and Sackett's experiments) and, we believe, will be adsorbed and complexed in the uppermost soil layers—^{234}U in the same chemical form as ^{238}U. If, either by groundwater or surface run-off from this soil, any leaching of uranium occurs, dissolved uranium should have the same AU (~1) as the soil, as there is no chemical difference between complexed ^{234}U and ^{238}U. Even after, say 1,000 yr, less than 3‰ of ^{234}U will be the more easily leachable 'recoil ^{234}U'.

Tritium measurements on precipitation and stream water in the Neckar system indicate that, for heavy precipitation, surface run-off contributes less than 5% to the river discharge. We presume that most of this run-off contribution originates in the inclined areas of the river spring system where horticulture should be negligible[2].

THE CHAIN STRAIGHTENERS
Fruitful Innovation – The Discovery of Linear and Stereoregular Polymers

FRANK M. McMILLAN

One of the most exciting stories in the history of Science – in the tradition of The Double Helix.

A narrative account of the remarkable burst of scientific discovery and technological innovation that gave science mastery over the 3-dimensional structure of high polymers and the world its most useful group of plastics and synthetic rubbers.

This book examines the personalities and the work of the key people involved and the controversies they aroused. Amongst these it pays particular attention to the seminal work of Karl Ziegler in Germany and Giulio Natta in Italy. This is a superb case study of the conditions under which fruitful innovation takes place; of the fortuity of many discoveries and their later rationalisation, of the continuity of science, the critical importance of alert observation, and the necessity of aggressive follow-up.

To be published in November by The Macmillan Press « £9.00 0 333 2529 7

The Sun: Our Future Energy Source

by **D.K. McDaniels**, *University of Oregon*

An elementary, non-mathematical introduction to the practical use of solar energy which discusses the background of the present energy crisis, the concept of energy, and the ability to meet the crisis with non-renewable energy sources. It reviews both the history of solar energy — assessing economic viability for space heating as compared with present energy alternatives — and the nature of the universe and the formation of the sun. Primary solar energy applications — space heating and cooling and solar electric power generation are examined and there is an annotated bibliography in each chapter and numerous illustrations.

Electromagnetic Fields

by **R.K. Wangsness**, *University of Arizona*

A straightforward, systematic introductory text in intermediate electromagnetism, emphasizing properties and sources of field vectors and clearly demonstrating shifts in concepts and points of view involved in the change from action at a distance to fields. It contains a macroscopic point of view throughout, with microscopic coverage in selected chapters. The author indicates motivations for each step in derivations and new concepts; and includes discussions on how to avoid common errors.

Electric, Optic, and Acoustic Interactions in Dielectrics

by **D.F. Nelson**, *Bell Laboratories*

A textbook and research monograph that treats a broad segment of the macroscopic physics of dielectrics by a first principles, unified, deductive method. It begins from a discrete particle point of view; constructs a continuum Lagrangian of a dielectric crystal of arbitrary symmetry, structural complexity, and nonlinearity in interaction with the electromagnetic field (accounting for all long wavelength modes of motion of the crystal — both optic and acoustic); and deduces remaining material from this Lagrangian. Numerous topics discovered or expanded over the past fifteen years are included.

October 1979 — 556 pages
0471 05199 3 — $40.00/£18.50

Optical Crystallography 5th Ed.

by **E.E. Wahlstrom**, *University of Colorado*

A modern, comprehensive review of theory and practice, with special reference to the passage of light through non-opaque substances examined under the polarizing microscope. It contains the minimum of mathematical treatments (included primarily to supplement diagrams portraying two- and three-dimensional relationships). This edition is extensively re-written and updated, with many new illustrations and an appendix on the theory of light reflection by opaque substances.

Pesticides: Preparation and Mode of Action

by **R.J. Cremlyn**, *Principal Lecturer in Organic Chemistry, The Hatfield Polytechnic, Hertfordshire*

This book discusses the general principles of underlying chemical pesticides, with a brief history of their development. It lists the main types of insecticides, herbicides, and fungicides, with a discussion of their chemical preparation, uses, and biochemical mode of action. Acaricides, nematicides, fumigants, molluscicides, and rodenticides are also covered, and some novel methods of pest control are discussed, such as use of juvenile hormone mimics, sex attractants, chemosterilants, and microbial insecticides. The book ends with a discussion of pesticides in the environment and of future development in pest control chemicals.

Stress Physiology in Crop Plants

edited by **H. Mussell** and **R.C. Staples**, *both of Boyce Thompson Institute, Cornell University*

An international source book, providing a balanced synthesis of basic and applied information on all aspects of plant response to environmental stress. Twenty-five scientists presently involved in stress research review both field observations on crop performance and laboratory observations. Coverage includes temperature, ion stress, drought, and physical stress, as well as a general examination of both disease and air pollution effects on crop yields.

October 1979 — 526 pages
0471 03809 1 — $43.25/£19.85

Modeling of Rivers

edited by **H.W. Shen**, *Colorado State University*

Based on notes delivered at the Institute on River Mechanics, these twenty papers cover the construction of mathematical models used for quantitative estimates in river behaviour analysis. Basic approaches and assumptions are emphasized and future research needs are discussed.

October 1979 — 996 pages
0471 05474 7 — $53.25/£24.50

Seepage and Groundwater Flow: Numerical Analysis by Analog and Digital Methods

by **K.R. Rushton**, *Reader in Civil Engineering, University of Birmingham,*
and **S.C. Redshaw**, *Emeritus Professor in Civil Engineering, University of Birmingham*

This book is concerned with the underground flow of water in porous media. This is normally classified in three groups — seepage, regional ground water flow, and radial flow to abstraction wells. It uses numerical methods to study practical problems because the use of analog and digital computer methods can produce solutions to problems which would be intractable by formal analytical and graphical means. *(Series in Geotechnical Engineering)*

Born's intimate reminiscences

P.S. Farago

My Life: Recollections of a Nobel Laureate. By Max Born. Pp.308. (Taylor and Francis: London; Scribners: New York, 1978.) £8.50; $17.50.

THE basic facts about Max Born's career can readily be found; there is an entry under his name in every respectable encyclopaedia. One aspect or another of his pioneering work is well known to any competent physicist; many received their first introduction to atomic and molecular phenomena from his *Atomic Physics.* Born himself wrote several retrospective essays, some of which are collected in the volume *My Life and My Views;* and an excellent study of his life and works appeared in 1971 in the Biographical Memoirs of the Fellows of The Royal Society. Yet there has been relatively little information about the forces which shaped his character and outlook, the motives which turned him from an average school-boy into a physicist of the greatest distinction, or his relations with the contemporary academic community and society at large. These and many similar questions are answered in this volume.

Max Born had just turned 50 and was at the height of his career when Hitler rose to power, and a few months later he was deprived of his position. He writes: "All I had built up in Göttingen, during twelve years' hard work, was shattered. It seemed to me like the end of the world". And in a way it was. He left Germany, and during his 20 years of exile he found no true spiritual home. After three years of limited security in a Cambridge lectureship he was appointed to the Tait Chair of Natural Philosophy at the University of Edinburgh in 1936. He stayed there until his retirement at the age of 70. The major part of the recollections, under the title "Good Old Days", was written here during the War. It takes the story up to 1925, including the birth of Quantum Mechanics. The second part, entitled "Tempestuous Years", is a more sketchy account of the rest of his active life, written in retirement in Germany when he was about 79. The Preface by his son tells us that these memoirs were written primarily for his family. Indeed the reader feels as if he were admitted to this intimate circle to witness Born re-living his eventful life. The narrative is loosely spun of several strands and presented in a discursive style.

Firstly, the story of his family. On his mother's side, rich and influential industrialists enjoying a life of luxury, highly educated amateurs and patrons of the arts (mainly music and literature), friends of and hosts to eminent artists of the time. "My father's ancestry", he writes, "was humbler in regard to all things of property and consequence in the world, but I believe that the essence of my nature is due to the Born clan". As the narrative unfolds there emerges a view of the social and political scene in Prussia about the turn of the century, and in Germany as a whole during the following decades.

Max Born in the 1920s

Against this back-drop one can see the working of the factors which shaped his remarkable character. A fixed reference frame was defined for him by the traditions of his Jewish ancestors, emancipated generations earlier. "They believed they differed from their neighbours only in respect of religion, for which they had hardly any use, and they were Germans by culture and custom". This deep-seated sense of identity, an "inextinguishable homesickness for the German language and landscape", played an important part in deciding him to return to Germany after his retirement.

Born's concept of right and wrong began to be formed at a tender age and crystallised early, under his father's guidance. He recalls touching examples of his father's methods of teaching "practical ethics". The moral code thus assimilated did not conflict in any way with the enjoyment of beauty in nature and in art, and with taking a fair share of all the pleasures of a full life.

Intertwined with the family saga there appears a vivid picture of the contemporary educational system, and of academic life with its social and professional facets, depicted first from the point of view of a student, and then as seen by a scientist of rapidly growing stature. Fascinating portrait sketches bring to life many unique individuals, his teachers, fellow students, eminent colleagues of several generations, and highly gifted pupils. Some are portrayed with affection and respect, some observed with critical eyes and some drawn in the style of mocking cartoons.

As the narrative progresses he overcomes his apparent reluctance to 'talk shop'. Bit by bit there emerges a complete, though non-technical, survey of his own work and his own assesment of its significance. Reading these passages one can catch a glimpse of the way his creative intellect worked and of the emotional response to recognition given or denied to him at various stages of his career. Some of his attainments he thought were overrated, others were not appreciated adequately. Above all, the lack of recognition for his contribution to the foundation of the principles of Quantum Mechanics left a very deep and long-lasting scar, healed only by the Nobel prize 28 years later, during his retirement.

Max Born and his contributions to our knowledge of the physical world became enduring features of the history of science. This volume of his reminiscences reveals a whole world unknown to the present generation, and through it one can piece together the complex personality of the narrator. His reflections on a philosophical seminar he attended as a student in Göttingen could stand as his testament: "I can quite well grasp Kant's idea that there are principles or categories of thinking which are the conditions of actual knowledge and which you can discover by investigating the structure of this knowledge. That is what we theoretical physicists are really doing — with the sole difference that we do not claim that our latest analysis is a final and irremoveable law, but just another step to a remote truth. To look for ultimate evidence by introspection, contemplation and verbal analysis, is irreconcilable with science, and seems to me in practical life the source of all ideological struggle. For anyone who believes he has obtained such an internal evidence easily becomes a fanatic, a mystical believer unapproachable by reason and argument". □

P.S. Farago is Professor of Physics at the University of Edinburgh, UK.

Parasite physiology

Biochemistry and Physiology of Endoparasites. By Theodor von Brand. Pp. 447. (Elsevier/North Holland/Biomedical: Amsterdam; New York and Amsterdam, 1979.) $87.75; Dfl.180.

THEODOR VON BRAND died in 1978 and parasitology lost the man who had pioneered the study of the physiology and biochemistry of parasites and whose name had become synonymous with the subject for almost forty years. von Brand was probably the best person to be able to overview the whole of this area of study and fortunately he managed to complete the text of this book before his death. This remarkable synthesis of a massive amount of information will remain as a tribute to the man himself and will join his previous works, *Chemical Physiology of Endoparasitic Animals* and *Biochemistry of Parasites,* two of the most influential books ever written on parasitology.

Biochemistry and Physiology of Endoparasites is an updated version of *Parasitenphysiologie* published in German in 1972. There are ten chapters each with between 170 and 550 references mainly from the 1960s and 1970s. The chapters include the obvious ones on nutrition, respiration composition, synthetic processes, degradation processes, and sensory, nervous, muscular and locomotory physiology, and less obvious ones on parasitic habitats, hormones, pathophysiology and the physiological basis of chemotherapy. There is therefore something of interest for everyone. Von Brand wrote beautifully and was also a master of synthesis: the essentials of whole papers are expertly digested and summarised in a few words so carefully chosen that anyone can understand them. This is a book for casual reading and for reference but it is as the former that it will be most useful. The committed parasite physiologist will have access to specialist reviews and literature retrieval facilities but even he should be able to use this book to put his work into some sort of general context.

A book of this kind cannot, of course, please everybody and it is stronger on helminthology than protozoology, physiology than biochemistry, and physiology proper than the rather newer fields of pathology, immunology and chemotherapy. This uneven coverage is inevitable and probably reflects real differences in our depth of knowledge of various aspects of parasitology.

It is customary today to criticise the price of books and in this case the publishers have done a considerable disservice to parasitology, which by its very nature is a subject of particular importance in the poorer parts of the world. The price will limit the purchase of this book to specialists who, for reasons given above, will learn least from it. This is a pity because this book summarises the state of the art; and as this subject is expanding so rapidly the preparation of a revised edition will be an impossible task. It is to be hoped that the publishers will find it possible to produce a cheap version for parasitologists in the tropics and students.

Had this been a cheap book the mistakes in it could have been forgiven but there are too many of them and they do mar the book and reduce its value as a work of reference. For example, there are inconsistencies in the spelling of names (Bernstein and Baernstein, Buelbring and Bülbring); the sources of figures and diagrams are given but do not appear among the references (Smyth (1969) on page 196 and Ryley (1967) pages 184-185); the names of parasites are not given in the captions to some of the figures (Figs. 41 and 49); and worst of all, and proof that these mistakes are not those of von Brand himself, his name appears under the Bs in the references to chapters 1 and 2 and the Vs elsewhere.

These shortcomings, however, are trivial compared with the importance of this book as a whole. No-one else will ever write a book of this kind and no parasitologist should fail to read it.

F.E.G. Cox is Professor of Zoology at King's College, University of London, UK.

Reichenbach's writings

Selected Writings, 1909-1953. Two volumes. By Hans Reichenbach. Principal translations by Elizabeth Hughes Schneewind. Edited by M. Reichenbach and R. S. Cohen. Pp. 500+435. (D. Reidel: Dordrecht, The Netherlands, Boston, and London, 1979.) Vol. 1: hardback Dfl. 145, $64.50; paperback Dfl.60, $27; Vol. 2: Dfl. 130, $59 and Dfl.60, $27.

HAD Hans Reichenbach (1891-1953) not died unexpectedly at the age of 62, a volume on him in the Library of Living Philosophers would have certainly gone beyond the stage of preliminary planning. According to the structure of volumes in that Library, an autobiography of Reichenbach would have been followed by a series of essays by other philosophers on the various aspects of his thought and a reply by him in addition to a list of his publications. This two-volume set contains such a list and starts with an autobiographical sketch followed by over thirty reminiscences by members of his family, friends, colleagues, and students which cover his childhood, university years, his first teaching post in Stuttgart's Technische Hochschule, his tenure at the University of Berlin, his stay from 1933 until 1938 at the University of Istanbul, and finally his years as a widely acclaimed professor of philosophy at the University of California in Los Angeles and a chief spokesman of logical positivism in the United States.

These reminiscences are full of illuminating gems about Reichenbach's life, work, thought, and personality which only the eyes of admirers could discern and retain for posterity. Anyone nurturing the notion that the Vienna Circle, of which Reichenbach was a prime mover as the founder of its organ, *Erkenntnis*, was given entirely to abstractions, can now learn from a most reliable source that Reichenbach considered himself a crusader. On hearing himself described as one whose sole interest was logic and epistemology, he reacted angrily: "But no! That is not true! The whole movement of scientific philosophy is a crusade . . . what I am doing aims as directly at social consequences as the programs of those who call themselves social reformers". The hitherto untranslated or no longer in-print publications of Reichenbach, which make up the bulk of these two volumes, have as their first group eight essays on social problems, written before and during World War I, with a strongly Socialist though not Marxist accent.

Equally instructive is Reichenbach's characterisation of the indispensability of philosophers: they (he means above all himself — witness his *The Rise of Scientific Philosophy* in which the modern part is largely limited to his own philosophy) are alone capable of articulating what the scientists, more often than not, brilliantly do but clumsily say. Reichenbach was a master of articulating not only the most abstract scientific notions and procedures (he had his own programme at the State Radio in Berlin), but also of handling down-to-earth matters. An engineer by training (he did not want to become an engineer "who can do nothing but calculate") he was competent in household repairs. He could deliver impromptu speeches on most obtruse topics, had touching sensitivity for others' needs, did pioneering work in interdisciplinary teaching, but, as stated in one of the reminiscences, was possessed "like most philosophers . . . of a strong sense of vanity".

The pride and centre of Reichenbach's philosophy was the probability theory of existence. He came to it partly through his early fascination with the kinetic theory of gases, partly under the impact of quantum theory, and partly because he took Einstein's relativity as a proof that questions about reality as such were meaningless. It was through Einstein's

theories of space and time that Reichenbach perceived the errors of Kantian metaphysics.

The items offered in Part II and Part III under the respective titles "Popular Scientific Articles" (21 items published between 1922 and 1932) and "General Scientific Articles" (11 items of which 10 were published between 1925 and 1933) give much insight into both Reichenbach's effort to develop a "scientific" philosophy, whose sole criterion of truth was physics, and into his keen interest in the latest developments of science.

Reichenbach is always his own voice even when he speaks of others, a desirable stance when taken by a great mind, but also rich in unintended instructiveness. The best example of this is provided in Reichenbach's writings on Einstein, his hero, whom he knew at close range, as he had attended with four others Einstein's first seminar in Berlin. There is no trace in these two volumes — judiciously selected, brilliantly translated, carefully edited and annotated — that Reichenbach had ever taken heed of the increasingly more emphatic endorsements by Einstein of a metaphysically realist epistemology and of his summary dismissals of positivism, including its "logical" brand.

The historian of science will not be surprised on finding that Reichenbach never makes as much as a modest effort to take a critical look at inherited clichés relating to scientific history (his reading of Kant's early scientific writings is very superficial indeed) and to live up to his professed premise to be respectful only of carefully established facts. Though largely uninterested in history, he did not, unlike some others in the Vienna Circle, forge facts (to recall a famous 'confession' of Feigl) to suit theories.

Two articles on ethics and free will, which as Part IV complete Volume I, are for all their brilliance in argumentation a perfect case of myopia concerning the circularity in which Reichenbach's classification of moral judgments as volitional decisions is caught. Is not Reichenbach's *own* decisional definition of cognitive meaning the very basis of that classification?

Volume II, which contains Part V ("Philosophy of Physics") and Part VI ("Probability and Induction"), is harder reading, but the gleanings are rich both for admirers and critics. The question of "now" as handled by Reichenbach in an essay of 1925 is a case in point. The existential, irreducible aspect of "now" never comes within his ken. The sole alternatives for him are choices between mathematical techniques, which he handles superbly, appropriate for deterministic and probability sequences, respectively. It was, of course, much later that Einstein reminded Carnap about "now" as something which slips through the nets of physics, but not so late that Reichenbach, a close friend of Carnap, could not have heard of it.

The most notable item in Volume II is a translation, under the title "The Aims and Methods of Physical Knowledge," of an essay originally published in 1929 in the section of the famed *Handbuch der Physik* dealing with the general foundations of physics. Reichenbach was obviously well known and highly regarded in the Germany of physicists, then the home of many major advances in theoretical physics. The very title of that essay cannot help remind one of a classic book of Duhem which was well known in German translation in the Vienna Circle. In the more than a hundred footnotes and bibliographical references of that essay, Duhem's name occurs not once, nor in the two volumes for that matter, a telltale sign of the narrowness which logical positivism can generate.

The last item in Volume II is a letter which Reichenbach wrote on March 28, 1949, to Bertrand Russell. Reichenbach hoped that a discussion of an hour or two would settle the dispute between them and then, as Reichenbach put it, "you would see that your abandonment of empiricism is unnecessary and that you need not resort to an extra-logical principle not based on experience". A vain hope, indeed. Russell had since long achieved a better grasp of the limitations of logic and method than the best which Reichenbach could ever muster.

Analytical flame spectroscopy

Fundamentals of Analytical Flame Spectroscopy. By C. Th. J. Alkemade and R. Herrmann. Pp. 442. (Adam Hilger: Bristol, UK, 1979.) £25.

THIS book makes an extremely good and successful attempt to treat the three branches of analytical flame spectroscopy — atomic emission, absorption and fluorescence — in a unified way. It provides the novice and afficionado alike with a sure guide to the understanding of the phenomena involved in atom production within chemical flames and their subsequent excitation for emission, absorption or fluorescence.

There are many books that treat analytical flame spectroscopy, but this one is probably unique in that it deals almost exclusively with the fundamental aspects of flame spectroscopy as they relate to practical analysis. Early on, the authors make the point that, although it is relatively easy to establish an analytical method based on atomic spectroscopy for the determination of a given trace element under defined circumstances, it is not so easy to extrapolate it to other conditions or to explain interferences and limitations. It is also difficult usually to establish successful adaptations without a knowledge of the fundamental processes that are involved. To this end the text incorporates the most relevant results of fundamental studies in atomic spectroscopy, the physics of collisions, chemical kinetics, combustion research, and so on. There are chapters on flame structure, pneumatic nebulisation, desolvation and volatilisation of analyte species, dissociation and ionisation, background emissionand absorption, shapes of analytical growth curves, and the classification of the interferences of concomitant substances. Throughout this treatment the three branches are dealt with synoptically or in juxtaposition so that their relative merits or limitations stand out clearly. There are also numerous references to the corresponding phenomena in electrothermal atomisation, thus enabling the reader to make his own assessment of the alternative (non-flame) atomisation technique.

The level of treatment assumes a basic knowledge of physics and chemistry that is possessed by most graduate students or experienced analysts who use atomic spectroscopy; it should not cause many problems to the average reader in this respect. It is also a matter of considerable satisfaction to find the authors using the terminology and nomenclature recommended by the Spectrochemistry Commission of the Analytical Division of the International Union of Pure and Applied Chemistry. These terms are defined in a glossary which reproduces the IUPAC report and, additionally, cross-references the earlier terms which abound in the literature. This section comprises 223 pages and is followed by a useful list of flame spectrograms showing the emission spectra of flames, hollow cathode lamps and atoms in flames. An index of flame spectra (lines and bands) is provided for the range 177.495-1252.2 nm to facilitate the identification of unknown peaks; and, finally, there is a comprehensive list of flame spectra arranged in alphabetical order of the elemental symbol. Over 900 references are cited and there is a comprehensive subject-author index.

There is no doubt that this is an extremely valuable book for background reading and general information for all who use analytical atomic spectroscopy in flames.

T.S. West

T.S. West is Director of the Macaulay Institute for Soil Research, Aberdeen, UK.

Comprehensive survey of the pulmonates

Pulmonates. Volumes 2A and 2B. Edited by V. Fretter and J. Peake. Pp. 540 and 150. (Academic: London, and New York, 1979.) £24.50, $50,.75 and £12, $25.20.

ANIMALS with high potential for colonising the land came into existence with the first appearance of the Gastropoda, of which the pulmonates form a subclass. The compact body was protected by an impervious shell with a restricted opening into which the broad foot was withdrawn; and the enclosed mantle cavity easily converted into a repiratory sac. Emancipation of the reproductive from the renal system made internal fertilisation possible and removed the last barrier to landward passage.

The subclass Pulmonata is classified into two orders. The modern Stylommatophora possess unique ingenuity in resisting the prime danger of dessication; and it is a rare terrain that is devoid of these animals capable of remaining dormant for the greater part of the year, even for years on end. In contrast the Basommatophora have returned to aquatic life — largely in freshwater, but in certain seas they are amongst the commonest intertidal limpets.

Dependence by the majority of snails and slugs on plant life has made them major competiors with man for food; and their association with other animals, notably in damp places, has made them admirable intermediate hosts for parasites. They are thus animals of high economic significance and for that reason also worthy of careful study.

These volumes represent the completion of a comprehensive survey begun in 1975 with the publication of a volume dealing with functional anatomy and physiology. In volume 2A treatment covers *systematics, evolution and ecology* presented in 10 chapters by highly competent authors.

With unique wealth of experience, B. Hubendick reviews systematics and comparative morphology in the Basommatopora revealing the range of structural variety from high spired snails to flattened limpets. This is followed by consideration from the equally authoritative pen of A. Solem of the data on which classification of the 20,500 odd species of land molluscs, almost entirely Stylommatophora, is based. In both chapters, unfortunately, references are largely restricted to those before 1972.

G.M. Davis, concerned with precise demarcation of species where transmission of human parasites is involved, reveals the importance of the new methods of chromatography, electrophoresis and immunology. This leads on to an account by C.M. Patterson and J.B. Burch of the results of work on the chromosomes of pulmonate molluscs. Chromosomes vary from 5 to over 70 pairs although variation is ussually conservative within the various taxa. B. Clarke and co-workers from Nottingham deal with genetic variation, showing how pumonates are particularly favourable material for demonstrating the action of natural selection on genetically determined visible characters.

Convergence is widespread throughout the Mollusca, the diversely originating slugs being notable examples. Liable to become major pests, control, as P.J. Hunter stresses, often depends on knowledge of their ecology. This leads on to the chapter by D.S. Brown on pulmonates as intermediate hosts for digenetic trematodes. No-one is better qualified than W.D. Russell-Hunter to discuss the ecology of freshwater pulmonates, and so we proceed by way of an account of the evolution of gastropods in ancient lakes by K.J. Boss to the final chapter on the distribution and ecology of the Stylommatophora by J. Peake, co-editor with Vera Fretter of these volumes.

Volume 2B entitled *Economic Malocology,* by A.R. Mead represents a continuation of its author's wonderful Giant African Snail (*Achatina fulica)* published in 1961. This supreme malacological saga tells of the spread by a surprising variety of agencies across Asia and then over the Pacific islands of this relatively immense high spired snail. Its supreme attempts to enter the United States, first by way of California and more recently by way of Florida, were only with difficulty repelled. This volume brings the story up to date and adds to the debt all malacologists owe to its author.

Enough one hopes has been written to reveal the range and high competence of these volumes and their importance to zoologists working on both pure and applied aspects of their subject.

C.M. Yonge

Sir Maurice Yonge is Honorary Fellow in Zoology at the University of Edinburgh, UK.

Peptide synthesis

The Peptides. Edited by Erhard Gross and J. Meienhofer. Pp.435. (Academic: New York and London, 1979.) $39.50.

THE publication of *The Peptides* by Schröder and Lübke in 1965 was a landmark in the literature of peptide synthesis. The intervening period has seen the continued rapid growth of the subject, both in the development of new methodologies (including solid-phase synthesis) and in biological importance, yet no major survey in the English language has appeared. This entirely new *The Peptides* edited by Gross and Meienhofer is thus particularly welcome. The overall scope of the multi-volume and multi-authored work has been widened as indicated by its subtitle, *Analysis, Synthesis, Biology*; this first volume deals with major methods of peptide bond formation.

The opening chapter (by Gross and Meienhofer) presents a broad survey of the properties of the peptide bond. The coverage is wide, embracing structure, cleavage and synthesis, and is necessarily superficial in some instances. A case in point is the section on conformational analysis in solution where the single example quoted (oxytocin) is atypical and gives a misleading impression of the field as a whole. It would now be generally agreed that in the absence of special constraints, short linear peptides have rather random conformations in free aqueous solution. Conformational analysis under these circumstances is less useful.

The following chapter (by J.H. Jones) surveys all the main methods for peptide bond formation. Much of the information is covered in greater detail in subsequent chapters. The author has perhaps wisely avoided overmuch comment on the relative merits and applicability of the various methods, though his personal experiences have been distilled most valuably into a section on the choice of individual activated esters. This is a useful introductory chapter, especially for the newcomer to peptide synthesis.

The following four chapters provide detailed coverage of the major methods of synthesis. An authoritative account by Bodanszky surveys a wide range of activated ester derivatives concluding with a most useful series of fully referenced tables. The azide and mixed carbonic anhydride methods are surveyed by Meienhofer. Inclusion of significant experimental detail in these chapters gives an excellent 'feel' for the various techniques. The carbodiimide method is reviewed by Rich and Singh. The volume is completed by a comprehensive account of the racemisation problem by D.S. Kemp.

It is inevitable that *The Peptides* will be essential reading for all engaged in or contemplating peptide synthesis. It will supplement (but not replace) the monumental reference work edited by Wünsch in Volume 15 of *Houben-Weyl's Methoden der Organischen Chemie* (1974). Further volumes of Gross and Meienhofer's compilation are awaited with great interest.

R. C. Sheppard

R.C. Sheppard is Head of the Subdivision of Peptide Chemistry in the MRC Laboratory of Molecular Biology, Cambridge, UK.

obituary

Sin-itiro Tomonaga, 1906-1979

SIN-ITIRO TOMONAGA, who shared the Nobel Prize for Physics in 1965, died on 8 July 1979 at the age of 73. His memory will be cherished for many years to come because of his witty personality and his sparkling ideas which contributed to the development of quantum electrodynamics in the post-war period.

Tomonaga was born in 1906 in Tokyo as a son of an eminent philosopher, and moved to Kyoto in 1913 with his family. In 1923 he entered the Third High School, and in 1926 he was admitted in Kyoto Imperial University where he specialized in physics. Through these years he became acquainted with Hideki Yukawa, another Nobel laureate, and they studied together. They remained lifelong friends.

It was in 1931, two years after Tomonaga graduated from the university, that he met Yoshio Nishina. Nishina, fresh from Bohr's Institute in Copenhagen, visited Kyoto to give a series of lectures on quantum mechanics. He brought back not only the celebrated Klein-Nishina formula but also the stimulating Copenhagen spirit to Japan and inspired in the young audience a fascination for the new frontier. This gave Tomonaga an excellent opportunity to enjoy Nishina's generous personality, so that the following year he decided to accept an invitation from Nishina to work at the Institute of Physical and Chemical Research in Tokyo as his research associate.

Nishina directed Tomonaga's interest to quantum electrodynamics, and they started to work together on this subject. This was the beginning of Tomonaga's life work, for which he was later awarded the Nobel Prize. Those stimulating days in the free atmosphere of the institute shaped a fertile brain that came into blossom a decade later. Tomonaga often recollected that the joint colloquia at the institute were a constant inspiration to him.

In 1937, he went to Leipzig to join the theoretical group led by Professor Werner Heisenberg and stayed there for two years. During his sojourn there he published a paper on thermal and mechanical properties of nuclear matter. In 1939, after his return home from Europe he was awarded the degree of Doctor of Science from Tokyo Imperial University upon presentation of his dissertation based on the outcome of his stay in Leipzig. In 1940, he married Ryoko Sekiguchi, a daughter of the then director of the Tokyo Astronomical Observatory. In 1941, he joined the

faculty of Tokyo Bunrika University which was later absorbed into the Tokyo University of Education in 1949.

At that time (1941) he concentrated his thoughts on a non-perturbative approximation method in meson theory which developed afterwards into the strong coupling theory, as well as on the generalization of Dirac's many-time formalism to field theory. In the same year World War II broke out, and everybody had to get through a very difficult time. However, Tomonaga's spirits were high in those days, and he was widening his repertory of specialities ranging from field theory to electronics. He completed a relativistically invariant formulation of the quantum theory of wave fields, the so-called super-multiple-time formulation, as the ultimate form of Dirac's many-time formalism. He had to wait for the war to end, however, before his theory could bear fruit: the renormalization programme. During the war he developed a theory of microwave systems as an application of the S-matrix formalism. He also clarified the oscillation mechanism of magnetrons on the basis of an intuitive model and secular perturbation. For these contributions he was awarded the Japan Academy Prize in 1948 together with his collaborator Masao Kotani.

When the war was over in 1945, Tokyo had been reduced to ashes, and everybody had to go through all kinds of hardships. Research on nuclear physics was banned in Japan, and the cyclotron built by Nishina was dumped in the Bay of Tokyo. Yet Tomonaga reached the loftiest pinnacle of his scientific activities in this post-war period. His deep-rooted idea on the renormalization programme was ripe, and he immediately started to work towards completion of his theory with his young associates. They gathered to hold seminars in the midst of ruins. At that time Japanese physicists had almost no access to scientific journals from abroad, but Tomonaga learnt of the discovery of the Lamb shift and its interpretation by Bethe through the popular science column of an American weekly magazine. This hint was sufficient to convince him of the correctness of his idea and soon he established his version of quantum electrodynamics. Another fruit was the formation of the Tomonaga school through his collaboration with young physicists in this period.

In 1949, Tomonaga was invited to the Institute for Advanced Study in Princeton and stayed there for a year. There, he broke new ground in the many-body problem.

In 1951, Nishina died, and Tomonaga had to assume many of his administrative responsibilities. After reaching the highest scientific achievement, Tomonaga then paid special attention, in Nishina's place, to the improvement of the working conditions of young scientists. He dedicated his best efforts to the cause of starting research laboratories and facilities such as the Norikura Cosmic Ray Observatory and the rebuilding of a cyclotron at the Institute of Physical and Chemical Research. He also took the leadership in establishing the Institute for Nuclear Study and later the National Laboratory for High Energy Physics.

In 1956, he was elected President of the Tokyo University of Education and remained in this position until 1962. Then he served as President of the Science Council of Japan from 1963 to 1969. Since 1964 he was President of the Nishina Memorial Foundation established to encourage young atomic scientists. This was the position that he held until his death. In 1965, Tomonaga shared the Nobel Prize for Physics with Julian Schwinger and Richard P. Feynman. His scientific achievement was honoured also with the Order of Culture, Japan, in 1952 and the Lomonosov Medal, USSR, in 1964. He

was a member of a number of academies and learned societies both domestic and foreign.

Almost a year ago I visited him in a hospital and we talked about a book he was preparing, but then I had not the slightest idea that I was never to see him again.

Kazuhiko Nishijima

Gilbert Stead

PROFESSOR STEAD, who died on 5 July 1979, aged 91, was one of a small group of physicists who helped to establish radiology as an independent medical discipline.

Medical interest in X-rays was sparked off by a lecture given by Silvanus Thompson to the Clinical Society of London in March, 1896, and during the next 25 years, largely through the enthusiasm of younger doctors with no special training, the use of X-rays for diagnostic purposes spread rapidly. These pioneers often built and maintained their own apparatus!

It was not until the Cambridge Diploma in Medical Radiology and Electrology (D.M.R.E.) was instituted in 1919 that such training became available. A course in radiological physics was begun by J.A. Crowther at the Cavendish Laboratory in 1920, with Rutherford's active support; S. Russ and L.H. Clark provided similar courses in London. In 1924, Stead took over the Cambridge teaching as University Lecturer in Physics as Applied to Medical Radiology and he continued it until 1938. From 1927 until 1942, when this Diploma was discontinued, he was also Secretary to the Diploma Committee.

Stead's connection with Guy's Hospitasl began in 1923 when he was appointed Reader in Physics in the Medical School, a part-time post. The facilities available there only allowed for under-graduate teaching, but in 1938 he was elected by the University of London to a Chair of Physics and was given proper laboratory accommodation. Unfortunately, the outbreak of war in 1939 caused evacuation to Tunbridge Wells and it was not until 1945 that he could begin to build up his department as a centre for applying physics in medicine.

He set up courses for the newer radiological diplomas which had been instituted by the University of London and by the Royal Colleges of Physicians and of Surgeons; and he acted as examiner for them at various times until he retired in 1953, having contributed greatly to setting the standards of teaching and examination which made these diplomas universally accepted. He was President of the British Institute of Radiology (the original Röntgen Society, founded by a group of medical men in 1897) in 1947/48 and delivered the Silvanus Thompson Memorial Lecture there in 1959. He was Honorary Consulting Physicist to Guy's Hospital and a Governor of the Medical School.

During his 30 years at Guy's Stead established a great reputation as a teacher. Some 3,000 undergraduates (who had to "do" physics in their first year, not always willingly!) attended his courses. Gentle in manner, patient and understanding their difficulties, he succeeded not only in overcoming their foibles but also in winning their affection. A text-book, *Elementary Physics*, which he wrote with such students in mind, is now (1979) in its eleventh edition; it was first published in 1923!

Stead outlived most of his contemporaries, but many younger people, not only in this country, remember his retiring, courteous personality. He was once described as "shrewd in discussion, wise in counsel and temperate in judgment." Those who had the privilege of working closely with him knew him also as a loyal friend.

C.B. Allsopp

Carl L. Hubbs

PROFESSOR CARL LEAVITT HUBBS, one of the world's most distinguished ichthyologists, doyen of that tribe in America, a true naturalist and a great personality, died on 7 July 1979 at the age of 84.

Born in Williams, Arizona, shortly after his mother was rescued by a train crew who had found her lost in the desert while driving a wagon, Carl Hubbs ended his distinguished career as Professor Emeritus of the Scripps Institute of Oceanography (University of California) where he had worked since 1944.

The early arousal of his interest in natural history he attributed to his maternal grandmother, one of the first woman physicians; it was further expanded by his father, a self-taught mineralogist, and was fully developed at Stanford University under the rigorous tutelage of that master ichthyologist David Starr Jordan. Hubbs obtained his bachelor's (1916) and master's (1917) degrees at Stanford, and his doctorate (1927) at the University of Michigan. After three years as a curator in the Field Museum, Chicago, he returned, for 24 years, to the University of Michigan. There, apart from his lecturing duties he was curator of vertebrates in the University Museum, and was responsible for building up that museum's collection of fishes, now one of the finest in the world.

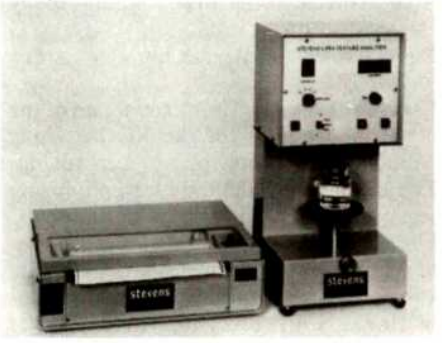
Hubb's command of ichthyology was awesome, his research interests extensive but penetrating; their results, published in over 600 papers, could never be criticised for being superficial or trivial. Perhaps the most characteristic feature of his taxonomic work was the way in which he took account of the animal's biology and viewed his subjects in their historical context. It is no wonder that Hubbs contributed so much to unravelling the historical biogeography of American freshwater fishes, nor that his interests should have turned to distributional problems in marine fishes as well. That, in turn, led him into oceanographical and meteorological research, while his freshwater studies took him into the fields of archaeology and human palaeoecology.

With his wife Laura, a mathematician and a dedicated companion, Carl Hubbs pioneered several studies into the genetics of fishes, in particular the application of hybridization studies to the systematics of several taxonomically "difficult" groups. Together they were responsible for discovering the now famous matroclinous and gynogenetic reproduction of the Amazon Molly, *Poecilia formosa*.

Problems of speciation and evolution, especially amongst the rich freshwater fish faunas of north and middle America, also attracted Hubbs. Interestingly, the phrase "new systematics" was first coined by him several years before it was used, apparently as a neologism, by Huxley as a title for that now classic collection of taxonomic essays he edited in 1940.

Conservation was a long standing concern of Hubbs'. He was instrumental in protecting forests, elk, fur seals, the Pacific gray whale and, after a forcefully conducted fight, the desert pupfish of Devil's Hole, Nevada.

That quite inadequate summary of Carl Hubb's research and influence on World ichthyology has overlooked his role in the development of many American research institutes and professional societies, his importance as a teacher, especially of post-graduate students, and his dedicated involvement in the more pragmatic aspects of his great love, ichthyology.



Many honours were conferred on him, including election to the National Academy of Sciences, the award of the Joseph Leidy Medal, the Shinkishi Hatai Medal of Japan, the sole honorary membership of the Japanese Ichthyological Society, and election to Foreign Membership of the Linnean Society of London.

Informally Carl Hubbs will long be remembered with warm affection by those who knew him, in particular by fellow ichthyologists for whom, irrespective of their status in the discipline, and despite his many commitments, he could always find time to share his knowledge and give his critical encouragement. Historically his contributions to ichthyology will ensure him a degree of immortality vouchsafed to few.

P.H. Greenwood

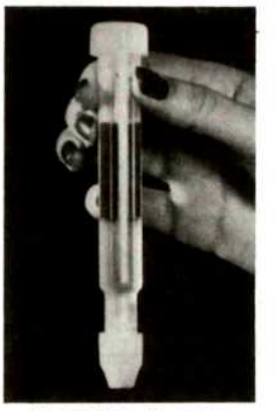
newly on the market

Texture analyser. Stevens. A very wide range of applications has been found for a new analyser made by Stevens Weighing Machines and originally designed for measuring the texture of foods. Called the Stevens LFRA texture analyser, the instrument is designed to perform a variety of tests where probes of different sizes and profiles are pressed onto or into products to determine factors such as gel strength, breaking point, hardness and consistency. Operation of the instrument, by push-button and thumbwheel selector, is quick and simple and the manufacturers claim high accuracy and reproducibility. To augment the digital readout, the instrument will power a chart recorder to provide hard copy of load, in grammes, as a function of penetration distance, in millimetres. The recorder automatically switches on at the beginning of each test cycle and operates during both the downward and upward travel of the probe. The probe load range is −1,000 g to +1,000 g in 1-g increments and probe speeds of 0.2, 0.5, 1.0 and 2.00 mm 5^{-1} can be selected.
Circle No. 276 on Reader Enquiry Card.

The Stevens LFRA texture analyser

Laboratory size fumigation chambers. GBEA Limited have now extended their existing range of fumigation chambers with the introduction of a laboratory size unit. Measuring 1.42 m × 1.14 m × 1.62 m, the unit has a volume of 1 m^3. Operation is simple, the trays of, for example, seeds or seedlings are loaded into the chamber which is then hermetically sealed before activation of the fumigation process. Following a pre-set period (normally 1–6 h) of dosing the produce with specially formulated methyl bromide gas, the fumigation process is completed.
Circle No. 277 on Reader Enquiry Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.



Inhalation chamber for toxicity testing. Wahmann. The 750-l inhalation chamber, specifically designed for toxicity testing through pulmonary exposure with various laboratory animal species is now available from Wahmann Manufacturing. The chamber is specifically designed to help research facilities comply with regulations of the Toxic Substance Control Act of 1977. All Wahmann Inhalation Chambers have removable caging and racking for any animal species. They are suitable for either acute or chronic studies in a broad spectrum of research testing. A free brochure with further information on Wahmann Inhalation Chambers can be obtained by circling the number shown below.
Circle No. 278 on Reader Enquiry Card.

Non-linear temperature programmer. Neslab. Non-linear temperature programs can now be performed over a range of −80°C to +150°C using Neslab constant temperature bath circulators with their new Model ETP-4RC non-linear electronic temperature programmer. This programmer will accept a signal from a computer, microprocessor or repeat cycle timer allowing practically any heat/cool configuration related to time.
Circle No. 279 on Reader Enquiry Card.

Water baths. Memmert. Anderman. The Memmert range of water baths covers sizes from 4 to 48 l capacity and the temperature range is from +25°C to +100°C. Water temperature is maintained by a liquid expansion thermostat which holds the desired temperature to within ± 0.5°C, and for high ambient temperatures a counter cooling coil is available for connection to the mains water supply. The latest waterbath, the WU 600 has the added advantage of a circulating pump incorporated into the bath housing. The pump gives a circulation of 30 l min^{-1} and is recommended if little temperature variation is required, especially with a fully loaded bath.

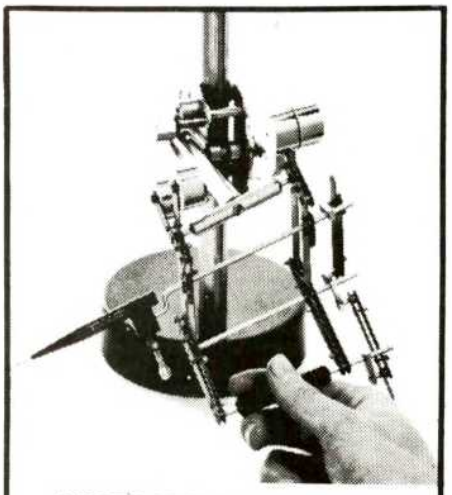
Microcomputer-controlled double beam spectrophotometers. Perkin-Elmer has introduced the Models 320 and 330, the double monochromator microcomputer-controlled UV-vis and UV-vis-NIR spectrophotometer. Both the models incorporate a grating–grating double monochromator. Instrument resolution is 0.07 (UV-vis) nm and stray light is less than 0.0001% at 220 nm, providing a photometric range of 4.0 Å.
Circle No. 281 on Reader Enquiry Card.

Separating tube. Life Science Laboratories have introduced the Separatube. This device is designed to simplify solvent extraction of samples. Made from inert plastic the Separatube is capped at one end and incorporates a needle-valve at the other, allowing controlled solvent run-off. This disposable item is particularly useful for pathogen or radio-isotope work.
Circle No. 282 on Reader Enquiry Card.



The Life Science Separatube

Multi-ingredient precision weighing system. British Aerospace Dynamics Group. Selectamix is a multi-ingredient industrial weighing control system developed by the Chiswick Division of British Aerospace Dynamics Group. Currently an eight-ingredient system is being evaluated. When a measuring sequence is initiated the Selectamix control will open the metering valve of the first ingredient until the increase in weight signalled by the load cell indicates that the correct proportion of ingredient 1 has been supplied. The first valve will then be shut and the second metering valve opened. The procedure is repeated until all eight ingredients have been measured, in sequence, into the production batch hopper in their correct proportions. Selectamix incorporates Random Access. Memory (RAM) and Erasable Programmable Read Only Memory (EPROM) facilities and is compatible with most existing computer installations.
Circle No. 283 on Reader Enquiry Card.

Orbital mixer. Wheaton Instruments has introduced an orbital mixer which will agitate the contents of large dishes, Petri dishes and slides. The speed of the multi-directional movement is steplessly adjustable over 9–45 c.p.m. The 280 × 280 mm supporting plate has a rubber surface for increased friction with the vessels. The mixer will accommodate a weight equivalent to 7 l of water.

Measurement of unbound moisture in powders and granules. Cosa Corporation. Rapid, on-site measurements of unbound moisture in powders and granules are made practical by the Michel VR2 meter with disk sensor. A small sample is simply scooped into the rugged disk sensor. Equilibrium is reached in a few seconds and the value is read from the meter's relative-humidity scale. Available from Cosa Corporation , the instrument and sensor make measurements in the range of 0.001–6% water and higher in some applications. The meter may be calibrated in equilibrium relative humidity to cover the typical range of 2 – 99% RH. Accuracy generally is 5% of scale deflection. The Model VR2 meter operates wherever it can be plugged into a 120 VAC outlet.
Circle No. 285 on Reader Enquiry Card.

Leak detector. Varian has introduced the latest model in its 936 series helium mass spectrometer leak detectors. Weighing only 25 kg, the 936-40 measures $21 \times 35 \times 50$ cm and is as portable and convenient as a small suitcase. A unique valve block design accurately positions roughing and foreline valves during the test cycle and prevents damage due to improper sequencing. The block is operated by a single handle on the system's cabinet. No liquid nitrogen is required.
Circle No. 286 on Reader Enquiry Card.

The Ross ER Series rotary relay

High-voltage rotary relay. Ross Engineering Corporation introduces the ER Series HV rotary relay, the newest addition to Ross' line of 5 kV to 300 kV PK Test high voltage relays. The ER-50 has a voltage rating of 50 kV PK Test with a continuous current capacity of less than 1 mA to 50 A or more. It is designed in a SPDT or DPDT configuration with standard actuator voltages of 115 V and 230 V a.c. (50 or 60 Hz) with other, a.c. or d.c., voltages and frequencies available. The ER Series relay can be used for HV transfer, capacitor discharge, polarity reversing, safety grounding, and tap and load selection. It is useful with a wide range of currents and has a high momentary current capability. It has fully visible contacts and is constructed using fire-retardant epoxy glass insulation.
Circle No. 287 on Reader Enquiry Card.

Glass knife holder. The introduction of the glass knife holder for the Reichert-Jung Autocut heavy duty microtome provides an inexpensive method for producing sections from plastic embedded materials. The 40-μm retraction on the return stroke of the Autocut's cutting cycle allows glass knives to be used for both dry and floated sections. Full ultra-microtome style orientation of the knife clearance angle, knife rotation in two directions and lateral movement of the holder are all built-in features. Its most important application is for the production of high quality methacrylate sections for light microscopy.
Circle No. 288 on Reader Enquiry Card.

Electroiontophoresis electrometer/transductor. W.P. Instruments. The Model 7160 electroiontophoresis/electrometer transductor from WPI features a light-weight, corrosion-resistant electronic probe allowing quiet recording in the 'current OFF' mode and any waveform, polarity or time sequence of injecting current (1 — 1,000 nA) in the 'current ON' mode. In the 'Stand-By' mode the probe tip will remain at or near zero volts until ready to use. The instrument has a voltage excursion range of ± 100 V over which the probe may swing.

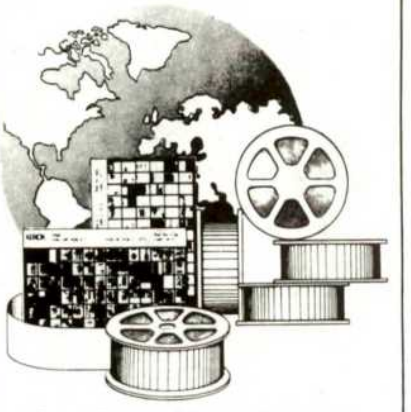
Dispenser. Alpha. A new 'mini' model in the established Millimatic Dispenser range has been introduced by Alpha Laboratories. The unit will dispense from 0.25 ml to 3 ml in 50-μl increments, repetitively, accurately and simply. Like all the other models in this range, the new Millimatic uses both major and vernier scales which lock positively into place making each volume adjustment a positive stop. The scales give a choice of over 60 different volume settings from one small unit. The reservoir is 500 ml and the unit is easily dismantled for maintenance and can be autoclaved. In addition, the 'mini' incorporates a new design of glass and ceramic valve which is now totally enclosed in a Teflon housing. A feature of particular interest is the bore of the fluid pathway which is wide enough to take fairly coarse particulate suspensions such as charcoal, kaolin and macroaggregations of albumin. This dispenser gives exceptional performance with an accuracy of better than 1% at 100 μl with even better results at the higher volume settings. It is also available as a diluter/dispenser with the same dispensing volumes and sample uptake volumes in the range 5–100 μl.
Circle No. 290 on Reader Enquiry Card.

Continuous CO_2 monitor. Beckman. The new LB-3 from Beckman, a continuously monitoring CO_2 analyser, is designed for applications in intensive care, neonatology, anaesthesia and neurosurgery. The LB-3's special, self-cleaning sampling system monitors the patient circuit for 4.5 min, then reverses gas flow through the sample lines for 30 s and cleans any accumulated moisture from the sample system. The analyser has audible and visual alarms for both high and low CO_2 levels, and a variable sample rate of 50 to 400 ml min^{-1}.
Circle No. 291 on Reader Enquiry Card.

TV Image analyser modules. Leitz announce the introduction of powerful new modules for its television-based image analysis system, TAS. A 100 gray level module scans an image or individual structures under software control for density histograms or reflectograms and returns integrated, normalised density values over a selected geometry. A module with a hardware arithmetical logic unit and binary image planes — each storing a complete threshold image — combines images at high speed. It can extract image detail, clean images, add and subtract images and set an image as a mask. This is done under the control of a comprehensive software operating system resident in a built-in microcomputer. All machine functions and image operations can be programmed in a BASIC-like language on a video terminal. The program can be stored for repetitive use.
Circle No. 292 on Reader Enquiry Card.

Magnetic hotplate stirrer. Cabburn Sterilizers. A new magnetic hotplate stirrer, which automatically reverses direction every 6s, and which has a top plate covered in white deconyl high density nylon to resist most spillages and abrasion, has been introduced by Cabburn Sterilizers. Called the Autorev-H, the unit measures 216 mm wide × 140 mm high × 210 mm deep. The 145-mm diameter hotplate is made of aluminium alloy in a natural finish, with the sheathed heating element moulded into the casting to ensure good heat transfer. The unit has a stirring capacity of up to 4 l, depending on viscosity. The Autorev-H incorporates controls including a single direction or automatic reversing illuminated switch, a speed control which is continuously variable over 100–1,450 r.p.m., an energy regulator control and a hotplate indicator light.
Circle No. 293 on Reader Enquiry Card.

MicroELISA readers. Dynatech have announced two entirely new 'through-the-plate' optical microELISA readers. A manual version capable of reading a complete ELISA plate in less than 5 min, and both print and analyse test results, and an automatic twin beam version which fully analyses and prints-out results of a complete MicroELISA plate in less than 1 min are also available.
Circle No. 294 on Reader Enquiry Card.



A Dynatech micro ELISA reader

Micromanipulator. Singer. The purpose of the Singer Microforge is to make easily from glass, micropipettes, needles both straight and curved, loops etc. The glass and heating element are viewed through a binocular eyepiece microscope with fine focusing. The glass and platinum heating element are held in fully adjustable and rotatable holders and the special feature of the instrument is that these holders are manipulated by two joysticks that move the work in the focal plane. This design advance makes possible, with little practice, the performance of intricate and complicated movements. The microscope and joysticks and other controls are conveniently mounted on a single rigid chassis within the instrument case. The heating element is thyristor controlled, and the element temperature is smoothly and finely adjusted by a large, conveniently placed knob.
Circle No. 295 on Reader Enquiry Card.

Crystal analyser. Siemens has developed a crystal analyser that will make a detailed structural crystal examination in about 1 min. The analyser achieves this by using a high-speed X-ray diffraction system coupled with a position-sensitive detector and associated electronics. The detector allows incident X-ray quanta to be located to within 50 μm on a high ohmic counter wire, even at relatively wide detector apertures. Consequently, the X-ray diffraction lines over a range of 5° can be recorded in a few seconds. Using the fastest goniometer speed (400° min^{-1}) a complete diffraction diagram may be recorded in a matter of minutes.

Cryogenic stage. Cambridge Instruments. A new cryogenic stage developed by Cambridge Scientific Instruments enables biological materials in the frozen hydrated state to be continuously examined and analysed in the scanning electron microscope at a temperature such that freeze drying and ice crystal growth cannot occur. The stage package comprises a specimen stage and airlock, a liquid nitrogen cooler transfer unit, a temperature monitoring unit, a specimen chamber anti-contamination plate and a transmission detector. It is easily attached to the current Stereoscans 150 and 604, and can also be readily fitted to the Stereoscans 180, S4 and S2A. Because of its ease of fitting and removal, the stage is not limited to only low temperature scanning electron microscopy. The transfer unit incorporates an LN2 chilled 'cold garage' into which the specimen is drawn, keeping it below −150°C.

Flow measurement and sampling systems. The Manning range of trade effluent flow measurement and sampling systems comprise a range of quick insert flumes covering a flow range of up to 0.85 x 10^6 gallons per day. The flumes are used in conjunction with portable flow-metering instruments which feature 24-hr and 7-d chart recorder functions, built-in integrators and sampler output for flow proportional sampling. Flowmeters are available with dipping probes or the latest ultrasonic devices. Installation and calibration of the flowmeter/flume systems may be achieved in a matter of minutes.
Circle No. 271 on Reader Enquiry Card.

Laminair flow cabinet. Laboratory Impex. One of the few laminair flow cabinets which conform to the new BS 5726 for Microbiological Safety Cabinet, is marketed by Laboratory Impex. With the Laminair HLB 2448 an even flow of air is drawn into a fixed working aperture, to first minimise the risk of particles escaping from the working area into the laboratory. The unfiltered room air is directed immediately to the first of three HEPA filters, without encroaching on the actual working area. Filtered air is ducted to the top of the unit where the flow is divided between that ducted to exhaust (to compensate for the continuous air inflow) and that to be directed onto the working area. An important feature of the Laminair system is that in both cases the clean air is HEPA filtered a second time. An additional benefit in the use of multiple HEPA filters is that the flow of air over the working area is truly laminair. Turbulence is virtually eliminated by the use of vertical interior surfaces.
Circle No. 272 on Reader Enquiry Card.

Arc lamps. The range of compact arc lamps from Canrad-Hanovia have been designed to provide optimum stability and performance in the widest range of applications varying from graphic arts equipment to solar simulation. Mercury-xenon lamps for enhanced UV output and stability, lamps for high overall intensity from a compact arc, and diffused arc lamps for medium intensity uniform illumination, are available in sizes from 35W to 30kW.
Circle No. 273 on Reader Enquiry Card.

Applications note on two-photon spectroscopy. Chromatix. A nine-page applications note describing the use of a flashlamp pumped tunable dye laser in two-photon spectroscopy is now available from Chromatix of Sunnyvale, California.

APPOINTMENTS VACANT

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
BONE & JOINT RESEARCH UNIT
LABORATORY SCIENTIFIC OFFICER

Required to assist in project involving production of monoclonal antibodies and research into the cause of rheumatic diseases. Knowledge of sterile techniques useful but not essential. The appointment is funded by The Arthritis and Rheumatism Council for an initial period of one year. Salary £3,888 plus £354 London Weighting.

For further details please telephone Miss McCall 01-247 8939 or apply in writing, enclosing full c.v., to Professor E.J. Holborow, Bone and Joint Research Unit, The London Hospital Medical College, Turner Street, London E1 2AD, quoting reference BJRU/11/79. 3647(A)

UNIVERSITY OF OXFORD
NUFFIELD DEPARTMENT OF PATHOLOGY AND BACTERIOLOGY
BACTERIOLOGIST

A bacteriologist is required to assist in the preparation of demonstrations and class material for the course in medical microbiology. Duties include assisting the lecturing staff and participation in research. Candidates should have a degree in microbiology or qualification as a technician, preferably with experience in medical microbiology.

Salary is expected to be in the £4,000 to £5,000 range depending on the qualifications and experience of the successful applicant.

Applications with curriculum vitae and names of two referees should be sent to Dr H.H. Johnston, Bacteriology Department, Level 7, John Radcliffe Hospital, Headington, Oxford. 3641(A)

ST. MARY'S HOSPITAL MEDICAL SCHOOL
DEPARTMENT OF VIROLOGY
Praed Street, London W2 1PG

A vacancy exists for a Junior Medical Laboratory Scientific Officer in the diagnostic section of this Department, which provides a District service. Candidates must have a minimum of 4 appropriate 'O' levels or preferably an ONC or science degree and must be prepared to follow the relevant courses of study leading to state registration as a Medical Laboratory Scientific Officer. Salary on a Whitley Council scale from £2,235 p.a. to £3,375 p.a. or from £2,535 to £3,501, depending on age and qualifications, plus London Weighting.

Further information from Mr C Kenny, Chief MLSO, tel 01-723 1252 ext 200. Applications should be sent to the School Secretary, St Mary's Hospital Medical School, Paddington, London W2 1PG. 3598(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(University of London)
DEPARTMENT OF NEUROLOGICAL STUDIES
RESEARCH ASSISTANT

Applications are invited from graduates for the post of Research Assistant to assist in a variety of laboratory projects connected with research in cerebrovascular disease (strokes). The post is available for two years.

Salary, according to age and experience, within the range £4,515 to £5,649 per annum (including £740 per annum London Allowance).

Applications, including curriculum vitae and the names and addresses of two referees should be submitted to Dr M J G Harrison, Institute of Neurological Studies, Sir Jules Thorn Institute, The Middlesex Hospital Medical School, London W1. 3600(A)

ASSISTANT REGISTRATION MANAGER

We are a major international company manufacturing ethical pharmaceuticals. The Company has been successful in recent years in identifying a series of valuable new drugs and has a continuing research programme involving further potential new drugs.
The Registration group is a small team of graduates whose principal function is the organisation of scientific data for presentation to the Committee on Safety of Medicines. The group works closely with the Scientific Information group.
The post of Assistant Manager in this department is now vacant. Candidates should be graduates in a biological science and should already have some experience of product registration or scientific information in the pharmaceutical industry. They should be familiar with the requirements of the Medicines Act. Facility in organisation of scientific data and the ability to write clearly and concisely on scientific topics are essential.
There is a possibility that a candidate with less experience could be appointed at a lower level.

Please apply to: Mrs J C M Andrews, Personnel Officer, Wyeth Laboratories, Huntercombe Lane South, Taplow, Maidenhead, Berkshire. SL6 OPH. Telephone Number: Slough 28311.

Wyeth Laboratories 3650(A)

UNIVERSITY OF LEICESTER
DEPARTMENT OF CHEMISTRY

Applications are invited for a
RESEARCH ASSOCIATE
to work with Professor M.C.R. Symons on various electron spin resonance projects of biological significance, for two years. Salary on scale £4,333 to £7,521.

Please contact Professor M.C.R. Symons, Head of Department of Chemistry, University of Leicester, Leicester LE1 7RH, as soon as possible. 3620(A)

UNIVERSITIES OF BRISTOL AND MANCHESTER
DARESBURY LABORATORY
POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for a postdoctoral research associate to coordinate an SRC collaborative computational project on molecular collisions. The project will involve the development of computer programmes for use at Daresbury and other centres. The post is based either at the Department of Chemistry, University of Manchester under Dr J.N.L. Connor or at the Department of Chemistry, University of Bristol, under Dr G.G. Balint Kurti or Dr J. Gerratt.

The location of the post will depend on the field of interest of the successful candidate. The project will be carried out in collaboration with Professor P.G. Burke's group at Daresbury Laboratory.

Salary within the range £4,333 to £5,199 pa. Superannuation.

Applications with curriculum vitae and the names of two referees to Dr J.N.L. Connor, Department of Chemistry, University of Manchester, Manchester M13 9PL by December 1st, 1979. 3583(A)

STRANGEWAYS RESEARCH LABORATORY
RESEARCH ASSISTANT

required to work as part of a small research team, on proteinases and proteinase inhibitors. Applicants should have a good Honours Degree, or H.N.C., preferably with several years experience of practical work in a biochemical laboratory. The post is for 3 years, with a starting salary in the range £3,768 to £4,232.

The successful applicant may have the opportunity to work for a higher degree.

Applications to Dr A.J. Barrett, Strangeways Research Laboratory, Worts Causeway, Cambridge CB1 4RN. 3616(A)

STANFORD UNIVERSITY
GEOCHEMIST —PETROLOGIST

The Department of Geology in the School of Earth Sciences invites applications for a faculty position beginning September 1980. Areas of interest include (but are not limited to) geochemical processes in the crust and mantle of the earth including isotope geochemistry, thermodynamics, kinetics, element distribution and phase equilibria studies. Teaching responsibilities might include graduate and undergraduate courses in geochemistry and igneous petrology. Level of appointment is open but we are particularly interested in creative young person, with a well established record in research.

Applications should include (1) a resume of education, professional experience, and published research; (2) a brief statement of plans for future research, and (3) the names of 4 referees. Send to: Prof. J.G. Liou, Department of Geology, Stanford University, Stanford, CA 94305, by December 1st, 1979. Stanford University is an equal-opportunity/affirmative-action employer. W329(A)

Scientific Careers on the fringe of the Lakes

We are responsible for the UK manufacture of Glaxo pharmaceuticals and their sale in this country.

Our Ulverston factory, involved in the production of bulk pharmaceutical products, incorporates one of Europe's largest fermentation works and is located in the southern part of the Lake District. The area is renowned for its natural unspoilt beauty and offers a wide range of recreational amenities.

Microbiologist

required in the Strain Selection Unit of Technical Services to join a multi-disciplinary team responsible for the selection and development of improved strains for production fermentations, including selection and screening techniques and inoculum development routes.

You should have a sound knowledge of microbial physiology, biochemistry and genetics, preferably with relevant postgraduate experience. An appreciation of statistical analysis advantageous. Close collaboration with multi-disciplinary scientific staff and liaison with University and research institutes will also be involved.

Fermentation Scientists

The Fermentation Pilot Plant Unit is responsible for development work on fermentation products on both pilot and main plant scale, optimisation of new strains, process modifications and new fermentation techniques.

One of the two appointments is an opportunity for a PhD or a good honours BSc in biological sciences, to lead one of the development teams. You should have three to five years' experience in fermentation technology, including team management. Good interpersonal skills and a proven record of implementing new ideas are also required.

The second appointment is in a development team and you should have a minimum of a good honours degree in biological sciences, and preferably some experience in fermentation.

For all appointments competitive salaries will be paid, together with the opportunity to participate in Glaxo Group profitability, and relocation expenses, where appropriate, to this very pleasant part of Cumbria.

Please write or telephone for an application form to: The Personnel Officer (RDN), Glaxo Operations UK Limited, North Lonsdale Road, Ulverston, Cumbria LA12 9DR. Tel: Ulverston 52261, ext. 92.

3645(A)

GLAXO OPERATIONS

THE UNIVERSITY OF ALBERTA
DEPARTMENT OF GEOLOGY
Edmonton, Alberta
Canada T6G 2E3

pplications are invited for a full-time ntinuing faculty position in the field of deposits/economic geology from uly 1980. Suitable applicants may have erience in any aspect of the mineralogy, rology or geochemistry of ores. The partment is exceptionally well equipped teaching and research in these areas of dy. The level of the appointment is n: the current base of the scale is ,696 plus fringe benefits.
pplications, with names of three rees, should be sent to the Chairman of Department, R. St J. Lambert, from m further details may be obtained. sing date 15 January, 1980. The iversity of Alberta is an equal-portunity employer. W491(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL
DEPARTMENT OF MEDICINE
POST-DOCTORAL IMMUNOLOGIST

required for work on the role of complement in induction of immunological responses. The project is supported by the Medical Research Council until October 1980 but there will be a continuing opportunity in the Unit for a suitable individual. For further details please contact Dr M.B. Pepys, Immunological Medicine Unit, Department of Medicine, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS or telephone 743 2030 extension 258.

Salary up to £5199 plus £740 London Allowance.

Application forms are available from and should be returned to the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 2/220.

3540(A)

LEEDS AREA HEALTH AUTHORITY (TEACHING)
EASTERN DISTRICT

ST JAMES'S UNIVERSITY HOSPITAL

Scientific Officer

Applications are invited from graduates with an Honours degree in one of the Biological Sciences for the post of Scientific Officer in the Regional Cytogenetic Unit established at this hospital, undertaking investigations required for patients within the Yorkshire Regional Health Authority.

Previous experience in cytogenetics is desirable, but not essential.

Application forms and job descriptions available from the Personnel Office — General Sector, Gledhow Wing, St James's University Hospital, Beckett Street, Leeds LS9 7TF. Tel: Leeds (0532) 33144, ext. 5103. 3608(A)

Pharmacologists

Bronchorespiratory Research

Roussel Laboratories Limited is one of the leading pharmaceutical companies in the UK. A vital part of the international Roussel-Uclaf organisation, it is engaged in the research development, manufacture and distribution of a range of important ethical pharmaceutical and allied products for use throughout the world.

One important area of current research is in new therapies for bronchial disease and we are looking for two suitably qualified pharmacologists to join an established team working in this field.

Recruitment will be at both PhD and first degree level. Candidates for the first post should have recently obtained or expect to obtain a PhD in a suitable branch of Pharmacology and be interested in the respiratory system and its diseases. Exceptionally, experienced graduates with a proven record of innovation will be considered. The second position will be of interest to graduates with a good first degree in Pharmacology, Physiology or a related science, preferably with some relevant experience.

The salary is competitive and benefits include free BUPA and life insurance, a contributory pension scheme and generous assistance with relocation expenses where appropriate.

Application should be made on our standard application form available from Rosemary Curtis, Assistant Personnel Manager, Roussel Laboratories Limited, Kingfisher Drive, Covingham, Swindon, Wilts SN3 5BZ. Tel: Swindon (0793) 24411.

ROUSSEL

3651(A)

THE QUEEN'S UNIVERSITY OF BELFAST

RESEARCH ASSISTANT

DEPARTMENT OF BIOCHEMISTRY

A research assistant (preferably with PhD) is required to investigate the immunoglobins and viral antibodies in sera from psychiatric patients. Experience in virology and/or enzyme immunoassay techniques would be an advantage.

The appointment will be made as soon as possible and will be until the 31st July, 1980 in the first instance with a possibility of renewal for two further years.

Salary scale: £4,335 to £5,778, initial placing depending on age, qualifications and experience.

Applications should be made to the Personnel Officer, Queen's University, Belfast BT7 1NN, Northern Ireland and should include the names and addresses of two referees. Closing date: 23 November, 1979. 3630(A)

ANGLO-EUROPEAN COLLEGE OF CHIROPRACTIC LTD

LECTURER

Applications are invited for the post of lecturer in Pathology, Microbiology and Haematology, as from 1st January, 1980.

The appointed person will be required to be responsible for the running of a small Clinical Haematology Laboratory in the College Clinic.

Applications together with curriculum vitae and the names of three referees to be sent to the Dean, Anglo-European College of Chiropractic, 1 Cavendish Road, Bournemouth, Dorset, BH1 1QX, as soon as possible. 3642(A)

UNIVERSITY OF PAPUA NEW GUINEA
(Port Moresby)

Applications are invited for the post of

CHIEF TECHNICIAN
in the
DEPARTMENT OF AGRICULTURE

Applicants should have a recognised qualification in Laboratory Technology, and experience relevant to laboratory work in an academic institution. Preference will be given to applicants with experience in agricultural or biological sciences.

The appointee will be responsible for the organization and administration of teaching and research laboratories of the department and for the provision of full technical services to teaching and research staff. In addition, the appointee will be required to design and implement an active training programme for National Technical staff. Duties will also include overall supervision of budgeting, purchasing of equipment, and control of stores and supplies.

Salary: K11,875 pa, (£1 sterling = K1.52). Family passages; baggage allowance; 3 year contract; 24% gratuity of which 5% is taxable; rent-free accommodation; overseas leave; education allowances; medical scheme. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to Assistant Secretary, Box 4820, University PO, Papua New Guinea by 14 December 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 3604(A)

BIOCHEMIST/ CELL BIOLOGIST

To conduct studies on various aspects of the synthesis, processing and secretion of proteins. Government/University laboratory. Academic appointment possible. Initial appointment 2 years.

Send resumé and research interests to Dr David V. Cohn, VA Medical Center, Kansas City, MO 64128. Equal opportunity employer. W499(A)

UNIVERSITY OF LIVERPOOL

POST-DOCTORAL BIOCHEMIST:

CONNECTIVE TISSUE RESEARCH

The Department of Veterinary Clinical Studies is to make an experimental study, over five years, of the changes in the biochemical structure of the uterine cervix at the time of birth in animals.

Applications are invited from candidates aged not more than 30 years, with a PhD, in an appropriate discipline and preferably with experience or interest in connective tissue biochemistry, to lead the investigation of the interaction of collagen with proteoglycans in cervical tissue.

The post is tenable as soon as possible, for three years, and may be extended for a further two years.

The initial salary will be within the range £4,333 to £6,355 per annum on a scale rising to £7,521 per annum.

Applications, together with the names of three referees, should be received not later than 29th November, 1979, by The Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/827/N. 3638(A)

INDIANA UNIVERSITY

DEPARTMENT OF CHEMISTRY

FACULTY POSITION

The Chemistry Department anticipates having a tenure-track position in Biochemistry. We are looking for a Biochemist with an interest in structure-function relationships with emphasis on the application of sophisticated contemporary tools to biological molecules or systems.

This position will require the ability to organize and present, effectively, courses at both the graduate and undergraduate levels. Moreover, potential candidates are expected to have a solid record of accomplishment in research and to show promise of developing vigorous, independent programs of scholarly investigation.

To apply, submit a brief biographical sketch, a publication list, names of three references, and a short resume of ideas for the development of teaching and research programs. Deadline for applications is December 1, 1979. Please apply to:

Dr Adam Allerhand, Chairperson, Department of Chemistry, Indiana University, Bloomington, Indiana 47405.

Indiana University is an Equal Opportunity/Affirmative Action Employer. W489(A)

POPULATION/ QUANTITATIVE GENETICIST

THE DEPARTMENT OF MEDICAL GENETICS

THE UNIVERSITY OF BRITISH COLUMBIA

Canada

Invites applications for a faculty appointment from individuals with demonstrated excellence in research in the field of population or quantitative genetics. Candidates should be capable of developing and teaching courses in population genetics.

The position is available July 1st, 1980. Members of this department act as consultants to the Health Surveillance Registry of British Columbia and, with the division of vital statistics of the province, have a record linkage project which together provide a unique data base for research.

Applicants should send an up-to-date curriculum vitae and names of three references, by January 1st, 1980, to Dr P A Baird, Dept of Medical Genetics, Faculty of Medicine, University of British Columbia, Vancouver, BC, V6T 1W5, Canada. The University of British Columbia offers equal opportunity for employment to qualified male and female candidates. W485(A)

MISSISSIPPI STATE UNIVERSITY

DEPARTMENT OF ENTOMOLOGY

ASSOCIATE FULL PROFESSOR

Applications are invited for a full time (1 mos.) appointment with rank of Associate or Full Professor in the Department of Entomology, Mississippi State University. The successful candidate will be responsible for research in pest management on field crop systems with particular emphasis on cotton and soybean insect problems, and for participation in ongoing interdisciplinary research to develop and apply insect-crop pest models and management systems. Teaching and guidance of graduate research will be expected in areas of insect ecology and/or population dynamics. PhD in entomology or relevant life science and experience in field crop research are required.

Experience in modelling and computer programming is desirable. Salary is negotiable and competitive. Application deadline: December 15, 1979. Job available January 1, 1980.

Send resume, list of publications and letters of reference to: Dr E.P. Pieters, Chairman, Search Comm., Entomology Department, Drawer EM, Mississippi State, MS 39762. Mississippi State University is an Affirmative Action Equal Opportunity Employer. W474(A)

THE UNIVERSITY OF PAPUA NEW GUINEA
(Port Moresby)

Applications are invited for the post of

LECTURER IN PHYSICAL GEOGRAPHY

to teach at introductory and advanced levels. Applicants should have a higher degree in a relevant discipline. Preference will be given to candidates with an interest in tropical land use and resource evaluation. The appointee will be required to contribute to courses in physical geography and man/land relationships. Ability to assist in courses in geographical techniques, and some experience in aerial photograph interpretation, are desirable. Tropical experience will be an advantage. There are opportunities for fieldwork funded by the University and by Government departments. The department has access to 4-wheel drive vehicles in the Port Moresby area and also along the Highlands Highway; a boat for nearshore work and laboratory facilities. Salary scale: Lecturer K11450 to 13300 pa (£1 sterling = K1.52). Family passages; baggage allowance; 3 year contract; 24% gratuity of which 5% is taxable; research support; rent-free accommodation; overseas leave; education allowances; medical scheme.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Secretary, Box 4820, University PO, Papua New Guinea by 30 November 1979. Applicants resident in the UK should also send one application to the Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 3601(A)

UNIVERSITY OF AUCKLAND
New Zealand

COMPUTER SCIENCE
SENIOR LECTURESHIP/ ASSOCIATE PROFESSORSHIP

Closing date 1 February 1980. Applicants for this position in the newly formed Department of Computer Science should be suitably qualified with a higher degree in Computer Science and have had considerable research experience. The person appointed will be expected to develop courses at both undergraduate and graduate levels and to participate actively in research.

GEOLOGY LECTURESHIP

Closing date 30 November 1979. Applicants should have a postgraduate degree in igneous petrology with a background in thermodynamics and the geochemistry of igneous rocks; some preference will be given to applicants with experience of the igneous associations of island arcs and continental margins of Pacific type.

Commencing salaries within the appropriate scale will be determined in accordance with qualifications and experience. Present salary scales are:

Lecturers: NZ$13,722 to $16,861 p.a. Senior Lecturers: NZ$17,285 to $19,780 p.a. Associate-Professors: NZ$24,879 p.a.

Conditions of appointment and method of application for all positions are available from the Assistant Registrar (Academic Appointments), University of Auckland, New Zealand or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications close on the dates stated. 3602(A)

PROFESSOR OF ZOOLOGY

The Department of Zoology at the University of Florida announces a position, starting September 1980, for a creative and productive scholar to be appointed as PROFESSOR OF ZOOLOGY. The responsibilities of this position will be to bring an active research program to the university, to teach a graduate course in his/her field, and to make a limited, but quality, contribution to undergraduate teaching. It is expected that the research interests of the successful candidate will fall within *comparative, ecological,* or *evolutionary* zoology. There is a preference for an appointment in the fields of the genetic aspects of evolution or the physiological ecology of aquatic invertebrates, but above all the appointment must meet the primal consideration of quality.

The salary will be commensurate with the rank, experience, and reputation of the successful candidate.

Direct inquiries and submit curriculum vitae, a statement of research interests, and the names of three referees to:

Brian K. McNab
Chairman, Professor Search Committee
Department of Zoology
University of Florida
Gainesville, Florida 32611
USA
(904/392-1178)

The deadline for applications is 1 January 1980.

An Equal Opportunity/Affirmative Action Employer. W498(A)

MEDICAL RESEARCH COUNCIL
MRC PNEUMOCONIOSIS UNIT
Llandough Hospital, Penarth, South Glamorgan, CF6 1XW

CELL BIOLOGIST — RESEARCH OFFICER

A graduate or equivalent (M.I.Biol., HND, HNC etc.,) is required in the Cell Biology Section, which is currently engaged in several studies on the cellular effects of pathogenic dusts.

Essential requirements are a good knowledge of Biochemistry and at least two years post qualification experience, which should include the use of sterile techniques. Experience in tissue culture would be advantageous.

The appointed person will be responsible to a member of the scientific staff but will be expected to assist in running the section and to conduct a certain amount of independent research.

The appointment will be made on the scale £4,134 to £5,595 (£4,614 to £6,102 from 1 January, 1980), depending upon experience.

Application forms and further details obtainable from the Assistant Administrative Officer. Please quote ref. 79/10. 3619(A)

CSIRO AUSTRALIA

Postdoctoral Research Fellows
Division of Environmental Mechanics
Canberra

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of who are research and professional scientists — located in Divisions and Sections throughout Australia.

GENERAL: Research in the Division is centred on processes of heat and mass transfer in the natural environment. Transport of energy, water, salts and gases in the soil-plant-atmosphere system are explored. The Division has 26 staff members at present including ten research scientists, working in the areas of soil physics, solar radiation, fluid mechanics, micrometeorology, and physical aspects of plant physiology. The Division is well equipped and has facilities for computing, mobile laboratories for study of the field environment, and an experimental field site located 45 km from Canberra.

Field: PHYSICS OF FERTILIZER USE — POSITION NO. 416/039

Duties: The Division's Physical Ecology Programme is investigating the exchange of gaseous nitrogen compounds between soils, plants and the atmosphere. This research is being broadened to embrace various physical aspects of fertilizer use: the efficacies of fertilizer placement; the transport of nutrients in soils by leaching and dispersion; nutrient absorption by plants and soils; the effects of the soil microclimate on microbiological activity and chemical transformations in soils. The work aims at improving agronomic techniques for fertilizer use.

The appointee will investigate, through theory and experiment, physical processes involved in the transport, absorption and loss of fertilizers applied to the soil.

Field: SOIL PHYSICS AND FIELD HETEROGENEITY — POSITION No. 416/040

Duties: The Division's Soil Physics Programme is concentrating on studies of the interaction between water and soil. The appointee will work within this framework, in a study of the variability of field soils and its consequences in terms of the field application of the theory of infiltration and redistribution of water in soil.

The following conditions apply to both positions:

QUALIFICATIONS: A PhD degree in an appropriate experimental field, a capacity for independent research, and an ability to apply the approaches and methods of physics and mathematics.

SALARY: Research Scientist: $A15,916 to $A19,509 pa. In exceptional circumstances an appointment may be offered at a higher level of salary.

TENURE: A fixed term appointment of three years is envisaged.

Applications **IN DUPLICATE**, stating **FULL** personal and professional details, the names and addresses of at least two professional referees, and **QUOTING THE APPROPRIATE REFERENCE NUMBER(S)** should reach:-

The Personnel Officer
Australian Scientific Liaison Office
Canberra House
Maltravers Street
LONDON
WC2R 3EH

by **30th November 1979**

Applications in U.S.A. and Canada should be sent to:-

The Counsellor (Scientific)
Embassy of Australia
1601 Massachusetts Avenue N.W.
WASHINGTON D.C. 20036 3613(A)

YEAST GENETICIST
The Brewing Research Foundation

has embarked recently on the development of recombinant DNA techniques for the genetic improvement of commercially important strains of yeast. A yeast geneticist is now required to join this project.

Candidates should recently have obtained (or expect to obtain shortly) a PhD; experience (preferably with *Saccharomyces*) in the construction and genetic analysis of mutant and recombinant strains is essential. Previous work on the inheritance of cytoplasmic genetic determinants and an interest in the regulation of gene expression would be advantageous. Appointments will be at an appropriate point between £4,600 and £5,600.

Applications, including curriculum vitae, and names of two referees should be sent to: The Assistant Director, Brewing Research Foundation, Lyttel Hall, Nutfield, REDHILL, Surrey RH1 4HY. 3633(A)

ASSISTANT KEEPER NATURAL HISTORY

Edinburgh

. . . to be concerned with the curation of the extensive insect collections. Responsibilities will include detailed revisional work, identifying specimens and registering accessions, dealing with enquiries from specialists and the public, maintaining data retrieval systems and planning exhibitions.

Candidates should normally have a degree with 1st or 2nd class honours or an equivalent or higher qualification in zoology and a good knowledge of the British species of at least one major insect order (preferably Coleoptera, Diptera or Lepidoptera). Knowledge of languages, especially French and German, and experience in field preparation work advantageous.

Salary: (from 1.1.80) as AK I £6650 — £11175; or AK II £4200 — £5950. Level of appointment and starting salary according to age, qualifications and experience. Non-contributory pension scheme.

For further details and an application form (to be returned by 22 November 1979) write to Royal Scottish Museum, Chambers Street, Edinburgh, EH1 1JF. Please quote ref: G(51)382.

ROYAL SCOTTISH MUSEUM

3655(A)

UNIVERSITY OF BATH

Applications are invited from suitably qualified candidates for the post of

LECTURER IN PHYSICAL CHEMISTRY

in the School of Chemistry. Preference will be given to applicants with research experience in heterogeneous catalysis or solid state chemistry.

Salary range £4,333 to £8,992 per annum.

Application forms and further particulars are available from the Personnel Officer, University of Bath, Bath BA2 7AY, quoting reference number 79/234. Closing date 30th November 1979.

3622(A)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BIO-MEDICAL PHYSICS AND BIO-ENGINEERING

SENIOR LECTURER (Hon. Principal Grade)

Physicist required to provide Radiotherapy Physics services and carry out development/research work and teaching in that subject. EMI-plan and other new techniques coming.

Salary on Senior Lecturer scale £8,698 to £10,775 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 30 November, 1979. 3632(A)

Brent and Harrow Area Health Authority
Brent Health District
CENTRAL MIDDLESEX HOSPITAL,
Acton Lane, London NW10

Research Assistant

Department of Gastroenterology

A Research Assistant is required to work on a Research Programme concerned with clinical nutrition. The work is concerned with investigating the pathophysiology of diarrhoea that occurs during Enteral Nutrition.

The post is for two years at an initial salary of £3,888 plus £354 London Weighting Allowance.

It is hoped that the appointee will register for a higher degree.

Applications with curriculum vitae should be sent to Dr D.B.A. Silk, Department of Gastroenterology, Central Middlesex Hospital, London, NW10.

3637(A)

UNIVERSITY OF HONG KONG

LECTURESHIPS/ ASSISTANT LECTURESHIPS IN ANATOMY

Applications are invited for appointment from 1 January 1980 to two posts of Lecturer/Assistant Lecturer in Anatomy. Applicants should be either dental, medical or science graduates with teaching experience in the subject. The appointments carry responsibility for teaching pre-clinical medical or dental students. The appointees will be expected to engage in research work.

Annual salaries (superannuable) are: Lecturer HK$67,920 × 4,560 — 77,040 BAR 81,600 × 4,560 — 113,520; Assistant Lecturer HK$49,500 × 4,620 — 63,360. (£1 = HK$10.70 approx).

Starting salary will depend on qualifications and experience. A medically qualified appointee who has completed his pre-registration year will be appointed as a Lecturer at the minimum point of the scale.

At current rates, salaries tax will not exceed 15% of gross income. Housing at a rental of 7½% of salary, education allowances, long leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or the Recruitment Section, Secretary's Office, University of Hong Kong, Hong Kong. The closing date for applications is 30 November, 1979.

3629(A)

RESEARCH ASSISTANT

Postgraduate Research Biochemist/Physiologist/Pharmacologist required to join a research team investigating various aspects of cardiac biochemistry and pharmacology. Experience in spectrophotometry, tissue metabolite analysis or isolated tissue perfusion would be advantageous. The research unit is located in the new Rayne Institute and appointments will be made through St Thomas's Hospital Medical School.

Applications together with a curriculum vitae should be sent to Dr D J Hearse, The Rayne Institute, St Thomas' Hospital, London SE1. 3550(A)

UNIVERSITY OF REGINA

DEPARTMENT OF BIOLOGY AND CHEMISTRY

POSTDOCTORAL POSITIONS

A two year postdoctoral position (salary approx. $14,500) is available in a molecular biology-biochemistry laboratory (headed by Dr H. Bertrand) studying the genetic control of the biogenesis of mitochondrial respiratory complexes in *Neurospora crassa*. The laboratory is well equipped for research on the assembly and function of submitochondrial complexes, restriction mapping of DNA, protein and nucleic and chemistry and for genetic manipulations.

A second postdoctoral position ($1,000 Cdn/month; ending June 30, 1979 with the possibility of an additional year pending budgetary approval) is available for research on the regulation of pyrimidine and arginine metabolism in *Salmonella typhimurium* (headed by Dr R.A. Kelln). Research activities will include mutant isolation, genetic mapping, nucleotide pool quantitation enzyme assays and protein and nucleic acid chemistry.

Interested individuals should be available as soon as possible and should have completed a PhD degree in biochemistry, genetics or physiology.

Applications, in the form of a curriculum vitae with names and addresses of three references should be sent to:

Department of Biology (or Chemistry), University of Regina, Regina, Saskatchewan, Canada S4S 0A2.

W487(A)

INVERTEBRATE ZOOLOGIST

A beginning

ASSISTANT PROFESSOR or INSTRUCTOR

position

is available July 1, 1980. Candidates must have Ph.D., potential for excellence in teaching and ability to develop an independently funded, high-quality research program. Teaching responsibilities include an introductory invertebrate zoology course with laboratory and field trips, an upper level course in the applicant's speciality, and participation in the Aquatic Biology Program. Research should be field oriented and focused at the organismal, population or community level — preferably with marine organisms. We prefer someone who will interact productively with faculty in such areas as physiology, ecology, ethology and evolutionary biology.

Applicants should submit a resume including research and teaching experience, future research plans, and a list of publications; and have three letters of reference sent by January 15, 1980 to: Dr J K Waage, Division of Biology and Medicine, Brown University, Providence, RI 02912.

An Equal Opportunity/Affirmative Action Employer. W500(A)

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANT

to work on experimental neuropathies employing freeze-fracture techniques. The post will be held jointly between the Department of Neurological Science at the Royal Free Hospital, Hampstead, and the Department of Anatomy, St. Mary's Hospital Medical School.

Applicants, who should have previous experience in electron microscopy, are requested to send a curriculum vitae and the names of two referees by 16 November, 1979 to Professor P.K. Thomas, Royal Free Hospital, Pond Street, London NW3 2QC, from whom further particulars may be obtained. 3646(A)

UNIVERSITY OF NATAL

DEPARTMENT OF CHEMISTRY

Durban

Applications are invited from suitably qualified persons, regardless of sex, religion, race, colour or national origin for appointment to the post of

SENIOR LECTURER/ LECTURER

in Physical, Analytical or Inorganic Chemistry.

Salary in the range:

Senior Lecturer	R11 400 — R15 600 per annum
Lecturer	R 8 100 — R13 200 per annum

The commencing salary notch will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus is payable subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, group insurance, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, 4001, Republic of South Africa, with whom applications on the prescribed form, must be lodged not later than 15th January 1980, quoting reference Adv. D83/79. W483(A)

Consultant in Applied Statistics

Amsterdam

c. £10,000 UK equivalent

This is a new appointment within the sizeable health care subsidiary of a major multinational, and will be based at the company's research headquarters near Amsterdam. Because of the increasing complexity of new product innovation and governmental requirements, there is an important need for an experienced Statistician to join a small and highly skilled team of internal statistical consultants.

The largest proportion of consultancy requests is concerned with human health problems. The emphasis will be on experimental design, study monitoring and data analysis—with the aid of an IBM 370 computer—and there will also be opportunity and the requirement to keep abreast of current applied statistical methodology. The span of the work will be broad, and a Consultant could expect to be involved in projects ranging from toxicology studies and clinical trial design on the one hand, to chemical development problems on the other.

Because of the technical demands of this appointment, the man or woman we seek must have mathematical/statistical qualifications to at least MSc level, combined with a minimum of 3 years' applied consultancy experience and an intelligent, realistic approach to practical problems. The ability to speak Dutch is not called for as English is widely spoken in the Company. However, good opportunity and facilities to learn the language will be provided.

The starting remuneration level will depend upon experience but, as an indicator, it should provide a standard of living broadly equivalent to some £10,000 in the UK. Generous removal expenses will be paid, including provision of a substantial tax-free allowance to help settling into a new home.

Please write in confidence for an application form, or phone if you would like to discuss the appointment further before applying.

THAMES POLYTECHNIC
SCHOOL OF MATERIALS SCIENCE AND PHYSICS
RESEARCH ASSISTANT

A Research Assistant is required in the Division of Physics to investigate the properties of amorphous semiconductors. The successful applicant will have a good honours degree in physics or electronic engineering and will register for a higher degree. Salary scale £3,321 to £3,705 inclusive.

Further particulars and form of application may be obtained from the Staffing Officer, Thames Polytechnic, Wellington Street, London SE18 6PF, to whom completed applications should be returned by 13 November, 1979. 3609(A)

CHARING CROSS HOSPITAL MEDICAL SCHOOL
(University of London)
DEPARTMENT OF BIOCHEMISTRY

Applications are invited from graduates in Science or Medicine for a research post funded by the Cancer Research Campaign to join a small group working on the possible use of lipid vesicles (liposomes) in cancer treatment. Experience in the field of tissue culture would be an advantage. Excellent opportunities exist for collaborative work with clinical departments.

The applicant should preferably be under 30 years; salary on scale £4,333 to £7,521 plus £740 London Weighting Allowance. Further details from Professor Brenda E. Ryman, Department of Biochemistry, Charing Cross Hospital Medical School, Fulham Palace Road, London W6 8RF.

Applications on forms obtainable from the School Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St. Dunstan's Road, London, W6 8RP. (Ref: 078) 3634(A)

UNIVERSITÄT FREIBURG
LEHRSTUHL FÜR ZELLBIOLOGIE
POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for this post to work on rRNA-binding proteins of the nuclear matrix. Experience in fractionation techniques of RNA and/or protein would be advantageous. The post will be for two years with possibility of renewal. The salary will be according to BAT II a (about 42,000 to 45,000 DM p.a.)

Applicants should write, enclosing full curriculum vitae, to: Dr F. Wunderlich, Lehrstuhl für Zellbiologie, Institut für Biologie II, Universität Freiburg, Schänzlestr. 1, 7800 Freiburg, Germany-W. Tel.: 761-2032680 W486(A)

UNIVERSITY OF PENNSYLVANIA
THE MOORE SCHOOL OF ELECTRICAL ENGINEERING
POSTDOCTORAL POSITION

The Moore School of Electrical Engineering, University of Pennsylvania invites applicants for a postdoctoral fellowship in chemical sensing at elevated temperatures. The research will involve the investigation of semiconductor devices in high temperature operation. A background in one of the following areas is required: electrical engineering, physics or chemistry. An interest in electronics and a working knowledge of computers is desirable.

Send resume and two letters of reference to Prof. J.N. Zemel, The Moore School of Electrical Engineering, D2, Department of Electrical Engineering and Science, University of Pennsylvania, Philadelphia, 19104. An equal opportunity, affirmative action employer. W481(A)

BLOOD PRODUCTS LABORATORY VACANCIES

Applications are invited for two positions in the Research and Development Department to work on new methods of plasma protein fractionation.

Protein chemistry, chromatography, electrophoresis and ultrafiltration are important features of the work together with the assessment of new plant and equipment in relation to the development of new procedures within a production environment.

Scientific Officer (REF. BPL/2)

The successful applicant is expected to possess Phd level qualifications in Biochemistry or a related life science and preferably experience applicable to the stated research problems.

Remuneration will be commensurate with qualifications and experience on a salary scale of £4,261 to £6,627 (under review) plus London Weighting. NHS superannuation scheme applies.

Technician (REF. BPL/18)

Applicants should possess a BSc, or its equivalent, in Life Sciences (preferably Biochemistry) and have experience in chromatographic and electrophoretic techniques. Salary is expected to be in the range of £3,768 to £5,391, plus outer London weighting. NHS superannuation scheme applies.

Application forms, available from Mr G.M. Bailey, Blood Products Laboratory, Dagger Lane, Elstree, Herts, WD6 3BX, should be submitted within 28 days quoting the appropriate reference number.

3636(A)

SCIENTIST BLOOD PRODUCTS

We require a scientist with a PhD in chemistry, biochemistry or the biological sciences, with some post doctoral experience, to work in the Department of Blood Products. Knowledge and interest in haemostasis is highly desirable. The person appointed will be responsible for quality control tests on certain blood products and will also have opportunities for individual and collaborative research, both locally and internationally.

The appointment is for 5 years in the first instance. Salary is on MRC scales, depending on age and experience.

Please write or telephone for further details and an application form quoting reference BL/035 to the Personnel Officer, The National Institute for Biological Standards and Control, Holly Hill, Hampstead, London NW3 6RB. Tel: 01-435 2232 ext. 200.

UNIVERSITY OF ASTON IN BIRMINGHAM

DEPARTMENT OF PHARMACY

INHALATION AEROSOL RESEARCH

A programme designed to optimise inhalation aerosols as a systemic drug delivery system will evaluate the effects of: 1) Formulation factors; 2) Physiological variables, and 3) Methods of aerosol generation upon the bioavailability of a marker drug administered in inhalation aerosols to experimental animals.

Applications are invited from persons with suitable post-graduate qualifications for the post of Research Fellow or Officer. Starting salary will be in the range £4333 to £4910 per annum. The programme will continue for a 3 year period but the appointment will be renewable on an annual basis.

Informal enquiries may be directed to Dr Peter R Byron, Tel 021 359 3611 Ext 277.

Application forms and further particulars may be obtained from the Staff Officer (quoting Ref No 381/6) University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET. (Tel: 021 359 3611 Ext 201) and application should be returned not later than 23rd November 1979. 3625(A)

University of Bradford

SCHOOL OF STUDIES IN SCIENCE & SOCIETY

Applications are invited for the post of

RESEARCH ASSISTANT

to work on a project concerned with the metabolism of 2.4D in plants.

Applicants should possess a good honours degree and have experience in the isolation and identification of plant hormones, and intermediate products. The appointment will be for one year.

Salary within range: £3,775 to £5,488 p.a. Further particulars/application forms obtainable from the Registrar, Ref: SS/RA/N University of Bradford, West Yorkshire, BD7 1DP. Informal enquiries to Professor Tom Stonier, School of Science & Society. 3640(A)

MEDICAL RESEARCH COUNCIL

DUNN CLINICAL NUTRITION CENTRE

Cambridge

NUTRITIONIST

Applications are invited for a Nutritionist with an interest in Medical Epidemiology to participate in a two year programme funded by the EEC Biology Medical Research Division concerned with food intake data in EEC countries. In addition to the collection and examination of existing data the applicant would be expected to work with a medical epidemiologist in the planning of future work to collect further data and to test various hypotheses on the role of dietary factors in the aetiology of common diseases.

Knowledge of French and/or German would be an advantage and a readiness to travel is essential. Experience in dietary assessment techniques and in the handling of large quantities of data will be required.

Salary according to experience.

Further details from and application to Dr W P T James, Assistant Director, Dunn Clinical Nutrition Centre, Addenbrookes Hospital, Trumpington Street, Cambridge CB2 1QE. 3643(A)

The Department of Pathology at the University of Pittsburgh School of Medicine wishes to recruit a member for its Division of Experimental Pathology. The position will entail research and teaching to medical students and to graduate students. There are ample clinical opportunities for research programs needing them. The major areas of interest in the Division are immunology and tumor biology.

The level of academic appointment will be commensurate with the candidate's qualifications.

Reply with Curriculum vitae to: Thomas J. Gill, MD, University of Pittsburgh School of Medicine, Department of Pathology, Room 716, Scaife Hall, Pittsburgh, PA 15261.

An equal opportunity/affirmative action employer. W495(A)

THE UNIVERSITY OF TEXAS AT AUSTIN

ASTRONOMY DEPARTMENT

invites applications for

TWO ASSISTANT PROFESSOR POSITIONS

These positions are regular, tenure-track assistant professorships with duties that include both teaching and research. Available research facilities include: the optical telescopes (2.7, 2.1, 0.9, and 0.8 m) of McDonald Observatory, the 2 mile 82 cm interferometer of the University of Texas Radio Astronomy Observatory, the 4.9-m antenna of the Millimeter Wave Observatory, as well as the CDC Cyber 170/750 campus computers.

Applications should include: a description of educational background, teaching, and research experience; a list of all publications; preprints of papers submitted but not yet published; and a statement of current research interests and future plans. Applicants should request at least three scientists who know the applicant personally to send letters of recommendation directly to: P. Vanden Bout, Chairman, Astronomy Department, RLM 15.220, University of Texas at Austin, Austin, TX 78712. Applications and letters of recommendation should be received by 1980 January 15.

The University of Texas at Austin is an Equal Opportunity Employer with an Affirmative Action Program. We encourage and welcome applications from all qualified persons regardless of sex, race, creed, national origin, or non-disqualifying handicap. W480(A)

A VACANCY EXISTS in the Department of Biochemical Pharmacology, Institute of Cancer Research (Sutton) for a post-doctoral fellow to join a small group of biochemical pharmacologists investigating the metabolism and modes of action of new and established anticancer agents. At present the major interest is in the field of antimetabolites. Candidates with broad interests in biochemistry and pharmacology are invited to apply. Salary will be in the range £4,910 to £7,521 pa (under review) plus London Allowance of £740 p.a.

Handwritten letters accompanied by a detailed curriculum vitae (in duplicate) and with the names of two referees should be addressed to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref 300/G/19. 3606(A)

UNIVERSITY OF HONG KONG

LECTURESHIP IN MICROBIOLOGY

Applications are invited for a post of Lecturer in the Department of Microbiology. Applicants who are not medically qualified will also be considered.

Annual salaries (superannuable) are: Clinical Lecturer HK$68,580 — 72,060 — 83,340 — 87,240 — 91,320 BAR 109,920 — 114,840 — 119,760 — 124,680 — 129,600.

Non-clinical Lecturer HK$67,920 × 4,560 — 77,040 BAR 81,600 × 4,560 — 113,520 (£1 = HK$10.70 approx.) Starting salary will depend on qualifications and experience.

At current rates, salaries tax will not exceed 15% of gross income. Housing at a rental of 7½% of salary, education allowances, long leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or the Recruitment Section, Secretary's Office, University of Hong Kong, Hong Kong. The closing date for applications is 30 November, 1979. 3603(A)

ROTHAMSTED EXPERIMENTAL STATION

Harpenden, Herts AL5 2JQ

Temporary SCIENTIFIC OFFICER

for one year from 1.12.79 to assist a team working on the genetic control of storage protein synthesis in barley and other cereals. The post is funded by the EEC.

Qualifications: BSc degree or equivalent qualification in a Biological subject with previous experience in Biochemistry. Salary £3,289 or £3,470 (£3,591 or £3,809 pa from 1.1.80), according to qualifications and experience.

Apply in writing to the Secretary giving names and addresses of two referees, and quoting Ref. 414 by 8th November, 1979. 3624(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF VETERINARY PATHOLOGY

Applications are invited for the post of Lecturer in the Department of Veterinary Pathology.

Preference will be given to veterinary graduates with interests and training in Clinical Chemistry, but applications are also invited from biochemists or recent veterinary graduates contemplating a career in this field.

The salary scale is £4,333 to £8,992 per annum.

Applications, together with the names of three referees, should be received not later than 15 December 1979 by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote ref: RV/825. 3571(A)

UNIVERSITY OF DUNDEE

Applications are invited for a newly established

CHAIR OF ZOOLOGY

in the Department of Biological Sciences. There is at present one other chair in the Department, the Boyd-Baxter Chair in Biology which is currently held by Professor W D P Stewart, FRS.

Further particulars are available from The Secretary, The University, Dundee DD1 4HN, with whom applications (ten copies or, if posted overseas one copy) should be lodged by November 22nd, 1979. Please quote reference EST/86/79J. 3576(A)

UNIVERSITY OF OXFORD

Genetics Laboratory

DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSISTANT GRADE 1A Ref: G/R/8

Applications are invited for the position of Post Doctoral Assistant (Grade 1A) funded by a grant from the Medical Research Council awarded to Dr I W Craig. The research concerns the characterisation of monoamine oxidase expressed in various human tissues and by cells in culture, and the application of somatic cell genetic analysis to the identification of genes responsible for the expression of this enzyme. Experience in the techniques of radioimmuno assay and of translation *in vitro* is desirable. The appointment, starting as soon as possible after 1st March, 1980, is likely to be for two years.

Salary on the scale £4333 — £6066.

Application, as soon as possible, including the names and addresses of 2 referees to: The Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU. 3649(A)

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF METALLURGY & MATERIALS SCIENCE

Pembroke St. Cambridge CB2 3QZ

POSTDOCTORAL RESEARCH ASSISTANT

The successful applicant will have expertise in transmission electron microscopy and a PhD in Metallurgy & Materials Science or in Physics. The project is to study (using electron microscopy; techniques to include hot-stage, X-ray analysis, high resolution and high voltage) the nucleation, microstructures and growth kinetics of intermetallic compounds in the reaction layers which grow during the fabrication and/or heat-treatment of composite A15 superconductors. There will be close collaboration, in an interactive programme, with an existing group investigating and optimising superconducting properties and with an industrial scale fabrication facility at Harwell. Prior research experience involving superconductors is not required.

Salary is on S.R.C. scales and the appointment is for three years commencing from 1st October, 1979 or as soon as possible thereafter.

Applications, together with curriculum vitae, should be sent to Dr J.E. Evetts or Dr E.R. Wallach at the above address. 3551(A)

UNIVERSITY OF EDINBURGH

RESEARCH ASSOCIATE IN CARDIOLOGY

A Research Associate in Cardiology is required to join an investigation team undertaking experimental studies into basic aspects of coronary heart disease. A good honours degree in Physiology or Pharmacology would be an advantage. Opportunity for study for a higher degree.

Initial salary within the range £4,333 to £5,488 p.a.

Applications to Professor M.F. Oliver, Department of Cardiology, Royal Infirmary, Edinburgh, by 30th November 1979. Please quote Reference 5062. 3639(A)

UNIVERSITY OF OREGON HEALTH SCIENCES CENTER

DEPARTMENT OF NEUROLOGY

POSTDOCTORAL RESEARCH POSITION

Position available immediately in physical or biological chemistry for research on cell surface chemistry and cell separations based on the membrane properties in two phase aqueous polymer systems.

Salary: $15,000 to start with increments in subsequent years.

Apply with résumé to Dr G.V.F. Seaman, Department of Neurology, University of Oregon Health Sciences Center, Portland, Oregon 97201. W488(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London)

TECHNICIAN 3 (Biochemistry)

equired to run a tissue culture facility. Qualification — O.N.D. or equivalent. Experience in tissue culture not required as raining will be given. The appointment is or two years and is sponsored by the Lord Dowding Trust Fund. Emoluments in the ange £3122 — £3553 plus £325 London Weighting Allowance. Application forms nd further particulars from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London, SW17 ORE. Closing ate 22 November 1979. 3653(A)

POST DOCTORAL POSITION

One Biochemist

One Neuroendocrinologist (with either a neurophysiological or biochemical background)

For studies on the developmental endocrinology of the pig foetus. Both positions tenable for an initial period of 12 months, starting 1980.

Applications including a curriculum vitae, full details of qualifications and the names of two referees should be sent by November 15, 1979 to Forschungsbereich Endokrinologie und Neuroendokrinologie, Institut für Tierzucht und Tierverhalten FAL, Mariensee, 3057 Neustadt 1, Federal Republic of Germany. W490(A)

HARVARD UNIVERSITY

BIOLOGICAL OCEANOGRAPHER

Harvard University seeks to appoint a tenured professor in the field of Biological Oceanography. Preference will be given to oceanographers with (1) a strong field and laboraory program dealing with the pelagic realm and encompassing work on the interaction between organisms and their environment or on groups of organisms, possibly including emphasis on a specific group; and (2) ability to offer high quality instruction in biological oceanography at both graduate and undergraduate levels.

Applicants should send a curriculum vitae and statement of research interests to: Farish A. Jenkins, Jr., Chairman, Department of Biology, The Biological Laboratories, Harvard University, 16 Divinity Avenue, Cambridge, Massachusetts 02138.

Harvard is an Equal Opportunity/ Affirmative Action Employer. W493(A)

CHURCHILL HOSPITAL RESEARCH INSTITUTE (University of Oxford)

Applications are invited for a BIOLOGIST

to join a research team investigating the effects of therapeutic doses of x-rays and fast neutrons on normal tissues. The successful candidate will be expected to participate in studies aimed at examining both physiological and histological changes in tissues after irradiation. The post, which is grant aided, is suitable for someone with a higher degree or equivalent research experience.

Further information and applications, with the names of two referees by 16 November, to Dr J.W. Hopewell, Churchill Hospital Research Institute, Headington, Oxford. 3549(A)

UNIVERSITY OF LEICESTER

DEPARTMENT OF PHYSICS

RESEARCH ASSOCIATE IN THEORETICAL PHYSICS

Applications are invited for a Science Research Council funded Research Associate to undertake a theoretical investigation of electron energy loss mechanisms in solids under the supervision of Professor J. L. Beeby. The Research Associate must have at least three years' postgraduate research experience in some aspect of theoretical physics, preferably solid state physics. The appointment will be for three years with a starting salary not less than £4,333.

Applications should be sent to Professor J.L. Beeby, Department of Physics, The University, Leicester LE1 7RH. 3610(A)

UNIVERSITY COLLEGE DUBLIN

Applications are invited by the Governing Body of the College for the following full-time statutory appointment:

PROFESSORSHIP OF GEOLOGY

Prior to application, further information (including application procedure) should be obtained from the Secretary and Bursar, University College, Belfield, Dublin 4. Telephone enquiries: 693244, ext. 431.

The closing date for receipt of completed applications is Thursday, 6th December, 1979. 3623(A)

EAST MALLING RESEARCH STATION

SUPERVISOR OF STATISTICAL COMPUTING SERVICES

Supervisor of data preparation and programming for the analysis of results of horticultural experiments on the Agricultural Research Council's dual ICL system 4 based network, with local RJE backed by a PDP8A mini-computer at internationally renowned Research Station conducting a wide range of basic and applied research.

Applicants must have degree in computing science with mathematics or statistics as a subsidiary or HNC in Computing science or equivalent and at least 5 years post qualifying experience for appointment at the higher grade.

Salary in scale £3,289 to £5,085 (£3,591 to £5,486 from 1.1.80) or £4,727 to £6,211 (£5,097 to £6,737 from 1.1.80) depending upon qualifications and experience. Non-contributory pension scheme.

Further details and application form from The Secretary, East Malling Research Station, Maidstone, Kent. 3599(A)

THE UNIVERSITY OF BRITISH COLUMBIA CLINICAL ENGINEERING PROGRAM

Applications are invited for the position of Director of Engineering Program. The director's responsibility will be the operation and development of a master-level program approved to start in September 1980. The director must hold an advanced engineering degree (PH.D. preferred), have several years clinical experience and be eligible for registration as a professional engineer in British Columbia. The appointment will be at the Associate Professor Level and applications should be sent, by January 1980 to: Professor Axel Meisen, Chairman Clinical Engineering Search Committee, Faculty of Applied Science, University of British Columbia, Vancouver, BC V6T 1W5. Canada. (Late applications may be considered). W503(A)

SCUOLA NORMALE SUPERIORE Pisa, Italy

POST-DOCTORAL POSITION

in Theoretical Physics is offered for a period of 10 months from 1 October 1980, for research in one of the fields: *astrophysics, plasma physics, particle physics, and field theory.*

Applicants may be of any nationality but must not be over thirty five on January 15, 1980.

The total salary attached to this position is 7 milion Italian lire. Successful candidates may apply for a partial reimbursement of travel expenses.

Applications should be sent by January 15, 1980 to the *Director of the Scuola Normale Superiore, Piazza dei Cavalieri, 56100 Pisa, Italy,* and should enclose a curriculum vitae, a detailed programme of study, and letters from three referees. W482(A)

UNIVERSITY OF DUNDEE

DEPARTMENT OF PHARMACOLOGY & THERAPEUTICS

Applications are invited for a new

CHAIR OF PHARMACOLOGY

to be filled within the Department of Pharmacology and Therapeutics from 1 October 1980. This will be a second Chair within the Department. The other Chair is that of Therapeutics held by Professor J. Crooks who, at present, serves as Head of the Department.

The salary will be at an appropriate point within the professorial range for UK universities.

Further particulars are available from The Secretary, The University, Dundee DD1 4HN, with whom applications (twelve copies) should be lodged by 29/11/79. Please quote reference EST/78/79J. 3626(A)

UNIVERSITY OF CAPE TOWN

DEAN OF THE FACULTY OF SCIENCE

The post of permanent full-time Dean of the Faculty of Science at the University of Cape Town will become vacant by the end of 1980 on the retirement of the present incumbent, Professor J S de Wet.

It is hoped that the new Dean will assume duty early in 1981, but the timing is flexible. We are seeking a scientist of distinction and standing who will be able to provide the necessary academic leadership. Interested persons should in the first instance contact Professor C von Holt, Chairman, Search Committee, Department of Biochemistry, University of Cape Town, Private Bag, Rondebosch 7700, South Africa. Alternatively, we would welcome suggestions for suitable candidates from our colleagues in the academic community. W501(A)

APPOINTMENTS VACANT

UNIVERSITY OF NOTTINGHAM
DEPARTMENT OF ZOOLOGY
A RESEARCH ASSISTANT

A Research Assistant with an honours degree in Zoology, Marine Biology or Biology is required to work with Dr D M Holdich (from 1 January, 1980) in the above Department for 3 years on a NERC-sponsored project on the systematics and ecology of British marine tanaid crustaceans. The work will involve systematic analysis of collections of material coupled with ecological observations on shallow water species off the west coast of Scotland. An aptitude for micro-anatomical work would be an advantage. Applicants should hold a current driving licence.

Salary commencing at £3775 per annum.

Registration for a higher degree may possibly be allowed.

Further details can be obtained from Dr D M Holdich. Applicants should send a curriculum vitae and names of two referees as soon as possible to the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. 3654(A)

UNIVERSITY OF READING
PLANT SCIENCE LABORATORIES
POSTDOCTORAL RESEARCH FELLOW

required in Department of Botany to continue an investigation, funded by Cancer Research Campaign, into the metabolism of nucleic acids during meiosis and gametogenesis in eukaryotic organisms. Preference will be given to applicants with a strong cell-physiological background, especially those with experience in electron microscopy.

The post is initially for a fixed period until 30 September 1980. It is hoped that there will be an extension until 30 September 1981 but this cannot be guaranteed.

Salary in range £4,333 to £5,199 p.a. plus USS superannuation. Apply, quoting Ref.MN78A, with curriculum vitae and names of two referees to Assistant Bursar (Pesonnel), University of Reading, Whiteknights, Reading RG6 2AH. 3621(A)

UNIVERSITY OF PITTSBURGH
DISTINGUISHED PROFESSORSHIP

A Chair of Molecular Biology is to be established within the Department of Biological Sciences. Conditions of employment, i.e. salary, lab space, funds for equipment and remodeling, teaching load, are exceptionally attractive.

Consideration will be given to truly outstanding investigators regardless of present rank working in diverse fields (i.e. neural and endocrine function, cell biology, gene regulation, etc.).

Curriculum vitae should be sent by individuals applying directly or by nominators to: Maurice Sussman, Professor and Chairman, Department of Biological Sciences, University of Pittsburgh, Pittsburgh, PA 15260.

The University of Pittsburgh, acting in the spirit and the letter of Affirmative Action regulations, actively encourages applications from women, minority members, and other individuals covered by the mandates of Title IX. W492(A)

FELLOWSHIPS STUDENTSHIPS

POSTDOCTORAL RESEARCH ASSOCIATESHIPS AT THE NAVAL MEDICAL RESEARCH INSTITUTE BETHESDA, MARYLAND

Sponsored by
The Naval Medical Research and Development Command
in association with
The National Research Council

Competitive applications are now being accepted for postdoctoral research associateships, starting 1 October 1980, in the areas of behavioral sciences, environmental stress, immunology, microbiology, parasitology, pathology, toxicology, and underwater biomedical research. Candidates must have received their doctoral degree (MD, PhD, DVM, or ScD) within the last five years. Salary will be $19,263 per annum.

Completed application forms are due not later than 15 January 1980. Information and application forms may be obtained by writing to the National Research Council Associateship Office (JH 608-N3), 2102 Constitution Avenue, NW, Washington, DC, 20418. An Equal Opportunity Employer. W497(E)

UNIVERSITY OF WESTERN AUSTRALIA
Perth
THE RAINE RESEARCH CENTRE FOR PERINATAL AND DEVELOPMENTAL BIOLOGY POST-DOCTORAL RESEARCH FELLOWSHIPS

The Centre is seeking doctoral graduates with experience in the following areas of research: Developmental cell biology, eg erythropoiesis or myogenesis; Molecular biology as applied to cell differentiation; Membrane biology and/or intracellular organelle synthesis; Electron microscopy applied to reproductive and/or developmental biology.

The Centre is situated in the Departments of Anatomy and Human Biology, Biochemistry and Physiology of the University of Western Australia. The Fellowships are intended for PhD graduates or those with equivalent qualifications, who by publication and in other ways have demonstrated significant research capability. The Fellowships will commence in 1980. Appointments will be made for two years in the first instance with the possibility of renewal for up to a further three years.

Commencing salary: $A16,291 per annum. The appointees will be entitled to an allowance of up to $A1,975 towards appointment expenses.

Further information about the Centre and its research activities and facilities may be obtained from Professor E.H. Morgan, Department of Physiology.

Applications in duplicate stating full personal particulars, qualifications and experience should reach the Acting Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009 by 15 December, 1979. Candidates should request three referees to write immediately to the Acting Staffing Officer. 3628(E)

Postdoctoral Fellowship

Applications are invited for a NRSA postdoctoral fellowship in association with a multidisciplinary Hematology Training Program at the Sloan-Kettering Institute for Cancer Research. The primary goals of the program are to train and conduct research in the following areas:

1. **Identification and characterization of erythropoietin responsive cells**
2. **Refinement of clinical bone marrow transplantation**
3. **Genetic disorders in red cell enzymes**
4. **Interaction of leukocytes with other hematopoietic elements and**
5. **Fundamental research of HLA**

The awards, for one year with the possibility of renewal, are open to United States citizens or permanent residents who have an MD, PhD or equivalent degree and who have had no more than 3 years postdoctoral experience. Please submit curriculum vitae and at least 3 letters of reference to:

Dr. Malcolm A.S. Moore
Director, Hematology Training Program
Sloan-Kettering Institute for Cancer Research
1250 First Avenue
New York, NY 10021

W496(E)

C.H. BEST FOUNDATION
POSTDOCTORAL FELLOWSHIP

Awarded in molecular endocrinology, molecular biology, differentiation, immunology, structure and function of membranes and lipid metabolism. Tenable for 2 years from 1 July 1980 with a stipend of $15,000 plus travelling and dependent's allowance.

Applicants with less than 2 years of postdoctoral experience should send curriculum vitae and three letters of reference before January 15, 1980 to: Chairman, Search Committee (Dr J. Dorrington), Banting and Best Department of Medical Research, University of Toronto, Toronto, Canada M5G 1L6. W484(E)

BRUNEL UNIVERSITY
DEPARTMENT OF BIOCHEMISTRY

Applications are invited from candidates who hold a good honours degree in Biochemistry for research studentships in the department. The studentship stipend and conditions will be those attached to SRC Studentships, and positions are available now.

The areas of study are in cancer research, free radical biochemistry and prostaglandin metabolism.

Applicants should sent full details of their academic career and experience to the Postgraduate Tutor, Dr J.T. Nodes, Biochemistry Dept., Brunel University, Uxbridge, Middx. 3627(F)

The Phyllis and Eileen Gibbs Travelling Fellowship 1980-81

BIOLOGY, ARCHAEOLOGY, SOCIOLOGY AND SOCIAL ANTHROPOLOGY

This Travelling Fellowship has been endowed with the object of assisting women graduates who have considerable experience of research and who intend to undertake fieldwork projects outside the British Isles (and normally not within their own countries of residence) in biology, archaeology, social anthropology or sociology — in that order of preference.

The Travelling Fellowship is open to women who are or have been members of any College or Approved Foundation or Approved Society in, or University Officers in, the University of Cambridge but preference will be given to present or former members of Newnham College.

Further details may be obtained from the College Secretary, Newnham College. *Applications should reach her by 1st January 1980. Please quote N/1/79.*

3631(E)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF SPACE RESEARCH

RESEARCH FELLOWSHIP

Ionic Reactions of Interstellar, Ionospheric and Environmental Interest

Applications are invited for a United States Air Force sponsored Post-doctoral Research Fellowship within the Ionic Physics Group whose interests are in the study of ionic reactions in planetary atmospheres and the interstellar medium. The successful candidate will be expected to concentrate on some aspects of reactions important in the Earth's atmosphere.

The appointment is tenable immediately until 30th September, 1981. Salary will be on the RF1A scale £4,333 to £7,521, plus superannuation. Maximum starting salary will be £5,199.

Further particulars are available from the Assistant Registrar (Science and Engineering), University of Birmingham, PO Box 363, Birmingham B15 2TT, to whom applications (3 copies) including a full curriculum vitae and naming three referees, should be sent by 16 November 1979.

Please quote ref: NE7. 3612(E)

THE ROYAL SOCIETY

JOHN MURRAY TRAVELLING STUDENTSHIP IN OCEANOGRAPHY AND LIMNOLOGY 1980

Applications are invited for the above Studentship, open to British graduates under the age of 35, for the encouragement of travel and work in oceanography or limnology. This award, which may be held for periods from three months to one year will in 1980 be up to £2,000, adjusted according to qualifications and place and duration of research. Applications are especially invited from workers in oceanography and limnology, as well as in zoology, botany, geology, mathematics and physics, and it will be permitted to hold the award while receiving a salary from a regular appointment. Applications receivable by 15 December 1979 should be made on forms obtainable from The Executive Secretary, The Royal Society, Carlton House Terrace, London SW1Y 5AG. 3605(F)

UNIVERSITY OF ST. ANDREWS

DEPARTMENT OF PHYSICS

POST-DOCTORAL FELLOWSHIP IN LASER RESEARCH

Applications are invited for the South of Scotland Electricity Board Fellowship in Laser Measurement Techniques, to develop excimer lasers and associated optical systems for studies of atmospheric gases.

The appointment is from 1st February 1980 for about 3 years ending 30th September 1982. Salary will be at the appropriate point on the Research Scale 1A (£4,333 to £7,521 per annum, under review) plus USS.

Applications, with curriculum vitae and names of two referees, should be sent by 23rd November 1979 to the Establishments Officer, The University, College Gate, St. Andrews, Fife, KY16 9AJ from whom further particulars may be obtained. 3618(E)

UNIVERSITY OF NOTTINGHAM

SCHOOL OF AGRICULTURE

Department of Applied Biochemistry and Nutrition

Applications are invited for a

CASE STUDENTSHIP

co-sponsored by RHM Research Ltd. The project is concerned with the synthesis and deposition of proteins in developing wheat grains.

Applicants should have at least an Upper Second Class degree in Biochemistry, Applied Biochemistry, Plant Physiology or relevant subjects.

Further details may be obtained from Dr G C Blackwood or Dr G Norton, Department of Applied Biochemistry & Nutrition, School of Agriculture, Sutton Bonington, Loughborough, Leics LE12 5RD (Telephone Kegworth 2386) to whom applications giving the names of two referees should be sent as soon as possible. 3648(F)

UNIVERSITY OF CAMBRIDGE

OPPENHEIMER RESEARCH FELLOWSHIPS

Applications invited for Oppenheimer Research Fellowships in the field of colloid science and surface chemistry, including applications to metallurgical reactions. Fellowships tenable for 3 years in a physical or biological science department, commencing 1.10.80, when applicants should be under the age of 30.

Stipend ranges from £4,333 (age 24) to £6,644 (age 32). Contributions towards research expenses and removal from overseas.

Applications to J R Payne Esq., University of Cambridge, 19 Trumpington Street, Cambridge CB2 1QA, by 31.1.80 including curriculum vitae, list of publications, statements of 1,000 words each of current research and proposed programme, names & addresses of 2 persons well acquainted personally and academically with applicant. Decisions will be made by 31.3.80. 3652(E)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MICROBIOLOGY

RESEARCH FELLOWSHIP

Applications are invited for a three-year MRC-financed research fellowship. Salary will be on the RF1A scale £4333 to £7521, plus superannuation. Starting salary will be up to £5488 according to age and previous (not necessarily related) postdoctoral experience.

The project is to study the chemical changes in virus-infected cells both *in vitro* and *in vivo* by X-ray microanalysis. The work will be carried out in two laboratories under the supervision of Dr J Stephen (Department of Microbiology, Birmingham University) and Dr T.A. Appleton (Department of Physiology, Cambridge University). Full provision has been made for travel between the two institutions and stays of short duration in Cambridge.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, PO Box 363, Birmingham B15 2TT, to whom applications (three copies), including full curriculum vitae and naming three referees should be sent by Friday 16th November, 1979. Please quote reference NM6(r). 3573(E)

STRANGEWAYS RESEARCH LABORATORY

BIOCHEMIST OR CELL BIOLOGIST

Applications are invited for a fellowship to study bone formation and the role of vitamin D. The position is tenable for three years with a starting salary, related to the University Lecturer scale, of up to £4,910 depending upon qualifications and experience.

Candidates with some post-doctoral research experience preferred. For further information telephone Dr Ian Dickson (0223) 43231.

Applications with the names of three referees should be sent to: The Administrative Secretary, Strangeways Laboratory, Worts' Causeway, Cambridge CB1 4RN before November 14th. 3615(E)

ASSISTANTSHIPS

UNIVERSITY OF LONDON KING'S COLLEGE

DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSISTANTSHIP

Applications are invited for a RESEARCH ASSITANTSHIP tenable at either the pre-doctoral or post-doctoral level and supported by the Medical Research Council. The project concerns the role of Ca^{2+} and cyclic-3',5'-AMP in stimulus-response coupling in human blood platelets. Experience and/or an interest in membrane and cyclic nucleotide biochemistry would be an advantage.

The assistantship is tenable from 1st January, 1980 for one year in the first instance with the possibility of renewal for a further two years. Consideration will be given to candidates qualified in disciplines other than biochemistry.

Applicants should send details of their qualifications, together with the names and addresses of two referees to Professor Michael C. Scrutton at the Department of Biochemistry, University of London King's College, The Strand, London, WC2R 2LS quoting reference 191697/N. 3611(P)

UNIVERSITY OF OXFORD

DYSON PERRINS LABORATORY

ß-Lactam Biosynthesis and Synthesis

POSTDOCTORAL RESEARCH ASSISTANTSHIPS

Applications are invited for Postdoctoral Research Assistantships supported by the N.R.D.C. to work on this project. This is a multidisciplinary rsearch effort and posts are available in the following areas:-

Microbiologists/Enzymologists. Experience in handling micro-organisms and cell free preparations would be desirable.

Organic Chemists. Synthetic and biosynthetic experience is required.

These appointments are initially for two years from 1st November, 1979, or as soon as possible thereafter. The posts will be on the Research Support Grade 1A at the appropriate point of the salary scale up to £6,066 p.a., according to age and experience.

Applications, with *curriculum vitae* and names and addresses of two referees, should be sent as soon as possible to Professor J.E. Baldwin, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY. 3617(P)

GRANTS and SCHOLARSHIPS

THE ROYAL SOCIETY

BROWNE RESEARCH FUND
MAURICE HILL RESEARCH FUND
MARSHALL AND ORR BEQUEST

Grants 1980

The Council of the Royal Society invites applications from qualified research workers for personal grants:

(a) from the Browne Research Fund, for research in marine biology at a marine biological laboratory or elsewhere. Preference will be given to those who propose to work on purely scientific problems rather than to those whose work would be primarily directed towards an economic end.

(b) from the Maurice Hill Research Fund (established in memory of the late Dr M N Hill, FRS, for the encouragement of research in physical oceanography and marine geophysics) for research at sea and/or in the laboratory in physical and chemical oceanography, marine geophysics and geology.

(c) from the Marshall and Orr Bequest for the support of marine biological research.

Grants may be used for periods up to one year, and are made on the understanding that university or other posts held by applicants will meanwhile be kept open for them. Recipients are permitted to use grants while receiving salaries from regular appointments.

In 1980 the total amounts available to be shared among all successful applicants will be about £4,500 from the Browne Research Fund, £9,500 from the Maurice Hill Research Fund and £7,500 from the Marshall and Orr Bequest; individual grants will not ordinarily be more than £750.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and returned by 15 December 1979. 3607(H)

COURSES

EMBO/FEBS/SKMB Advanced Laboratory Course on "Molecular Biology of Membranes" 14-27 September 1980 Biocenter, Basel Switzerland

The course will include review lectures, specialized lectures and laboratory experiments. Main topics to be covered will include the physical chemistry of membranes, membrane reconstitution and analysis of membranes by biochemical, genetic and immunological methods.

Laboratory space will be available for 24 students. The course fee will include Swiss Francs 100 for registration and approximately Swiss Francs 500 for accommodation and food. Fellowships will be available. Applicants will be selected on a world-wide basis.

Application forms can be obtained from the organizers. Deadline for application is April 1, 1980. Organizers: G. Schatz and J Seelig, Biocenter, University of Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland. Tel. 061/25 38 80. W502(D)

COURSES continued

CARDIOTHORACIC INSTITUTE

British Postgraduate Medical Federation
University of London
Fulham Road, London, SW3
(associated with The National Heart and Chest Hospitals)

COURSE ON PHARMACOLOGY OF ASTHMA

11th — 14th December 1980

This Course is designed for chest clinicians or scientists with an interest in asthma. Lectures, given by hospital and institute staff and by invited speakers, will cover clinical description and management of asthma as well as current views on the proposed mode of action and clinical experience of drug use in this disease.

The fee is £75 which is inclusive of lunches, refreshments and hospitality. There will be a cheese and wine party on Thursday, 13th December at which wives/husbands will be welcome.

Applications should be made to Mr. R. A. Perkins, Secretary, Cardiothoracic Institute, Fulham Road, London, SW3 6HP (Tel: 01-352 8121) from whom a copy of the programme will be available in due course.

London School of Hygiene and Tropical Medicine and The Royal Postgraduate Medical School

(University of London)

MSc IN MEDICAL MICROBIOLOGY

Advanced academic and practical training in bacteriology, virology, immunology, mycology, microbial genetics and medical parasitology as applied to clinical and preventive medicine is provided through an intercollegiate course of study extending over two years.

The first year will be spent at the two Schools of the University followed by a second year at a recognised laboratory. Candidates with satisfactory evidence of prior supervised practical training may be exempted from the second year of study.

The course is open to medical, dental and veterinary practitioners, graduates in science or pharmacy and other suitably qualified students.

Exemption from the Primary Examination for the MRC Path may be granted to successful candidates. The course is accepted as recognised training for College examinations.

A limited number of Medical Research Council awards may be available to suitably qualified British subjects resident in the United Kingdom.

Closing date for applications: 1 March 1980.

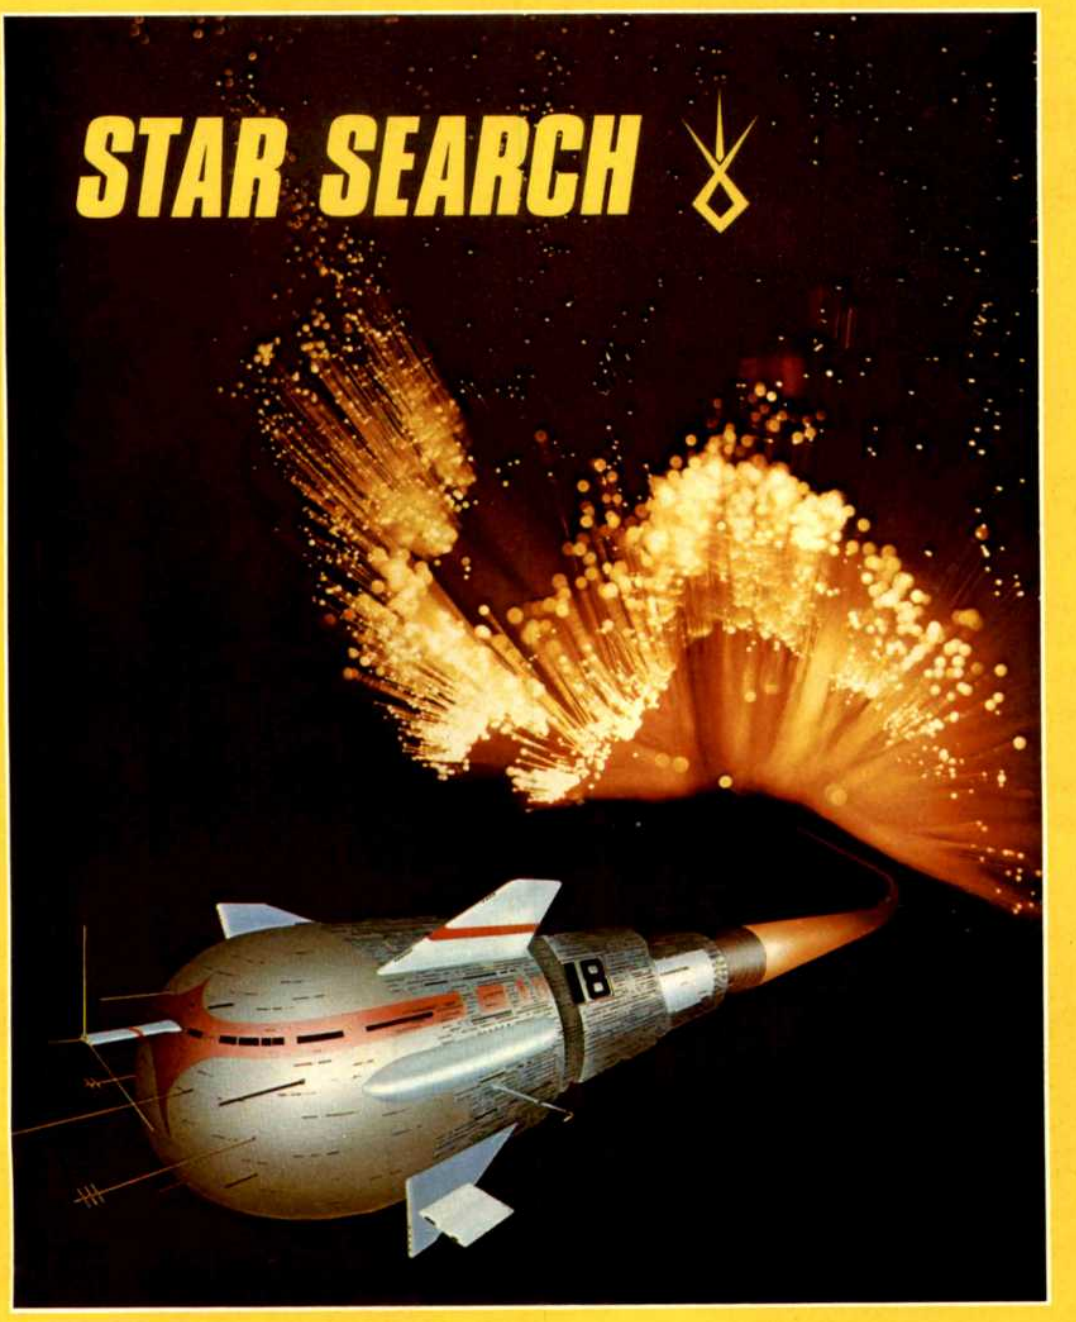
Further particulars from the Registrar, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT. 3597(D)

ANNOUNCEMENTS

A NATO Advanced Study Institute on Chemically Sensitive Electronic Devices will be held at the Peddie School, Hightstown, NJ from 9 June to 21 June 1980. The fundamental principles of transducer action for chemical sensors, the resulting device physics and selected areas of application will be presented in a series of lectures by: P Bergveld and G A Bootsma, Twente Technical University; R Buck, University of North Carolina; G Farrington, General Electric; M Green, Imperial College; T. Matsuo of Tohoku University; I Lundström of Linköping University; I Lauks and J N Zemel, University of Pennsylvania; S Pace, Stauffer Chemical.

This course is primarily intended for the young researcher at the post doctoral level but consideration will be given to anyone in the process of initiating research in these areas. The student body will be sought from a broad range of disciplines such as: electrical engineering, chemistry and chemical engineering, physics, material science and biomedical science and engineering. Limited travel and living assistance is available. Special arrangements are being made to provide low cost travel to and from the Peddie School.

For further information and applications write to either:



J N Zemel
University of Pennsylvania,
Moore School/D2,
200 S. 33rd Street,
Philadelphia, Pa. 19104. USA.

P Bergveld

A thousand million is a concept almost impossible to visualize. Yet this is the minimum requirement in miles per hour* for the deep space exploration which many scientists believe is man's hope for the future.

Such a concept was however established at BDH as far back as 1967 with the introduction of 'ARISTAR' very high purity chemicals. Utilising the very latest manufacturing and analytical techniques it was possible to establish a range of materials with specifications defining impurity limits in parts per thousand million. The range has been continually expanded to meet the needs of modern chemistry.

. . . the stars, tomorrow's hope; 'ARISTAR', today's reality!

* light speed, usually expressed as 186 000 miles per second, is almost 1 000 000 000 mph.

The British family Wilj announce two talented new members

Gamma Counter 2001-S

* 50mm Crystal, 50mm shielding
* Multiple-channel facilities (SMIC)
* Additional user variable window
* Digital display directly in KeV
* Accepts alternative external counting heads
* Incorporates our unique easy to calibrate system

RIA Data-Processor 2701

* Easy to use — it asks you the questions
* Dual-channel
* Choice of curve fits : Polylinear, Logit/log & Spline
* Statistical checks

These two new additions increase Wilj's long lead on other lower-cost RIA equipment. This combination can count and process **double-isotope kits** in one simple operation.
Higher energy isotopes can be counted with the larger crystal and increased shielding.

Data-processing is no problem with Wilj peripheral options. Teletypes, paper tape, data-logger and the Hewlett-Packard 9815A programmable calculator and software can all be accommodated.

Whichever combination you choose, all Wilj products come complete with an unconditional 2 year guarantee. (U.K. Only)

ORGANELLE HEREDITY
Nicholas W. Gillham

"This well produced book, with its ample references, is a mile-stone in the history of genetics."–Nature
"Likely to be the standard reference for many years."–Science
"A compendious, well-researched, beautifully illustrated and highly readable book."–Quarterly Review of Biology
"Especially appealing to geneticists, but it should also reach a rather wide audience among other specialists and students."–Trends in Biochemical Sciences
617 pages, 7 x 10, $64.35 (1979)

PROSTACYCLIN
Editors: John R. Vane and Sune Bergstrom

This volume reviews in comprehensive fashion our current understanding of the chemistry, physiology, and pharmacology of prostacyclin and its analogs. Much of the text focuses on the interaction between prostacyclin and thromboxane A_2 and its relation to the health of the cardiovascular system.
472 pages, $49.40 (1979)

NEURAL GROWTH AND DIFFERENTIATION
International Brain Research Organization (IBRO) Monograph Series, Volume 5
Editors: Esmail Meisami and Mary A.B. Brazier

This important new volume sponsored by IBRO addresses the questions of how nerve cells develop the intricate connections that underlie their function and how injury to nervous tissue can be compensated for by remaining structures. Topics discussed include biochemical and physiological studies of cells, synapses, and receptors during the neural differentiation process; model systems used to study neural development; problems of specificity, plasticity, and regeneration in the developing and adult nervous system; and approaches to the study of the human nervous system.
568 pages, $49.40 (1979)

REVIEWS OF NEUROSCIENCE, Volume 5
Editor: Diana M. Schneider

CONTENTS: Steroid hormone interactions with the brain: cellular and molecular aspects–*B. S. McEwen* / Sexual differentiation of the brain: implications for neuroscience–*R. E. Harlan, J. H. Gordon, and R. A. Gorski* / Neuroendocrine control of adult sexual behavior–*L. G. Clemens and B. A. Gladue* / Cerebellum in tissue culture–*F. J. Seil* / Calcium in the nervous system–*S. D. Erulkar and A. Fine* / Subject index. 256 pages, $20.80 (1979)

ADVANCES IN CYCLIC NUCLEOTIDE RESEARCH
Volume 11
Editors: Paul Greengard and G. Alan Robison

This series, one of the most prominent in pharmacology and biochemistry, provides the field of cyclic nucleotide research with a continuing, authoritative, centralized medium of communication and reference. 370 pages, $45.50 (1979)

VASCULAR NEUROEFFECTOR MECHANISMS
Editors: John A. Bevan, T. Godfraind, Robert A. Maxwell, and Paul M. Vanhoutte

This volume provides a detailed review of our present knowledge of neural control of the vascular system. Sections deal with the biochemical and physiological methods used for the study of blood vessel responses to neurotransmitters; neurohumoral regulation of the vascular system; differences between blood vessels in different regions of the vascular system; and pathophysiological states, such as migraine and hypertension. 370 pages, $38.35 (1979)

THE RETICULAR FORMATION REVISITED
International Brain Research Organization (IBRO) Monograph Series, Volume 6
Editors: J. Allan Hobson and Mary A.B. Brazier

This volume focuses on two major conceptual developments that have changed our thinking about the role of the brain stem in conscious state control. The first is an amended concept of the reticular formation as a "nonspecific" system arising from evidence of precise connectivity that is functionally related to specific sensorimotor integration of the head, eyes, and axial musculature. The second is the modification of the concept of reticular activation of the CNS engendered by the discovery of the aminergic neuronal systems of the brain stem. 544 pages, $51.35 (1979)

ADVANCES IN INFLAMMATION RESEARCH
Volume 1
Editors: Gerald Weissmann, Bengt Samuelsson, and Rodolfo Paoletti

SECTION HEADS: Membranes and Blood Vessels / Inflammatory Cells / Circulating and Local Mediators of Inflammation / Immune Mechanisms of Inflammation / Arachidonic Acid-Derived Mediators of Inflammation / Anti-inflammatory Drugs and Pharmacological Studies / Clinical Studies / Subject Index. 660 pages, $64.35 (1979)

Raven Press *1140 Avenue of the Americas / New York, N.Y. 10036 / U.S.A.*

Circle No. 05 on Reader Enquiry Card.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

VIRAL HEPATITIS Etiology, Epidemiology, Pathogenesis and Prevention

G. Vyas, S. Cohen, and R. Schmid, editors

A case-bound book covering the proceedings of a major worldwide symposium held in March 1978 and sponsored by the University of California. The proceedings include 32 comprehensive reviews, 25 discussions, four panel discussions, and 12 workshop summaries, bringing up to date all research on viral hepatitis and creating plans for future cooperative studies.

LC#78-00882, 748 pp., October 1978. **$64.50**

PROBLEM SOLVING AND COMPREHENSION A Short Course in Analytical Reasoning

Arthur Whimbey and Jack Lochhead

A textbook for high school and college students, psychologists, and teachers demonstrating the art of thinking clearly. There are many example problems and solutions that show how the experts solve problems.

LC#78-22121, 258 pp., 1979. **$8.50**

PROBLEM SOLVING

Monthly newsletter devoted to problem solving research and instruction in university and industry. *Problem Solving* provides an overview of the issues and a forum for ideas in problem solving; as well as information on vital contacts and sources of information in this important new field. The editorial board includes Goery Delacôte of the University of Paris, Jill Larkin of Carnegie-Mellon University, Leslie Fox of Oxford University Computing Laboratory, and Robert Karplus of the University of California, Berkeley, among others.

June/May **$18.00**

NUTRITION AND CANCER, An International Journal

Gio B. Gori, PhD, Editor **Lon Crosby, PhD, Assistant Editor**

An international and multidisciplinary journal that covers the etiology, prevention, and therapy of cancer as related to diet and nutrition. Aspects include clinical and experimental research in nutrition, carcinogenesis, epidemiology, anthropology, toxicology/pharmacology, biochemistry/metabolism, food production, and prevention. Quarterly.

Vol I: (1978-1979): $48.00, U.S., $56.00, Foreign Vol II (1979-1980): $60.00, U.S., $72.00, Foreign

BULLETIN OF MAGNETIC RESONANCE

The Quarterly Review Journal of the International Society of Magnetic Resonance

J. Howard Bradbury, editor

Contains reviews on the theory and practice of nuclear magnetic resonance, electron paramagnetic resonance, and nuclear quadrupole resonance spectroscopy including applications in physics, chemistry, biology, and medicine. Quarterly.

$18.00, members; $35.00, nonmembers; $50.00, libraries.

Announcing:

NUTRITION IN HEALTH AND DISEASE

Diversified journal dealing with clinical nutrition, preventive medicine, and the results of laboratory research in these and other topics relating to nutrition. A primary journal, it is peer reviewed. To begin in 1980. Price not yet set.

INNOVATION AND THE AMERICAN ECONOMY

The Fourth Franklin Conference

The Fourth Franklin Conference will examine the state of innovation in America, the relationship of innovation to the economy, and action that the corporate sector and government can take to foster innovation. To be held November 29, 30, 1979. To be published in 1980. $8.95.

EXERCISE AND SPORT SCIENCES REVIEW, Volume 7

Robert S. Hutton and Doris I. Miller, editors.

Annual publication of the American College of Sports Medicine, in which reviews of research concerning physiological, biomechanical, behavioral, and kinesiological aspects of movement behavior and human performance appear. Topics in Volume 7 will include Localized Muscular Fatigue: Role of Muscle Metabolism and Substrate Depletion, Biomechanics of Overarm Throwing Movements and of Throwing Injuries, and Physiology of Swimming Man. To be published early in 1980. $25.00.

Circle No. 12 on Reader Enquiry Card.

INDEXES

Annual Indexes are available for the years 1971-1978. The year's papers are listed by both author and subject.

Prices: UK: £5.00
Rest of World US$10.00

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World: US$6.00,
three for US$16.00.

To order, please send details and correct remittance to:

Nature,
Circulation Department,
Macmillan Journals Limited,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

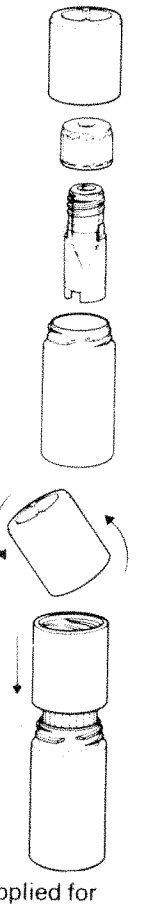
Using Iodine-125?

New Microvial*

- reduced exposure
- reduced contamination risk



Reduced exposure

The new packaging consists of 2 parts

- An outer plastic container incorporating a steel shield
- An inner plastic vial with a conical glass insert containing the iodide solution

Reduced contamination risk

The cap of the plastic outer container is keyed so that it can be used to unscrew the cap of the inner vial — no need to handle this vial from start to finish.

Banbury Report 2 — Mammalian Cell Mutagenesis: The Maturation of Test Systems

Edited by **Abraham W. Hsie,** *Oak Ridge National Laboratory;* **J. Patrick O'Neill,** *Oak Ridge National Laboratory; and* **Victor K. McElheny,** *Banbury Center*

1979, 504 pp., illus., bibliography
Cloth, $45

0-87969-201-4
LC 79-21186 CIP

Proceedings of a meeting held at Banbury Center in May 1979 on progress with using mammalian cells in culture to detect mutagenic chemicals. The meeting brought together geneticists and researchers who are developing mammalian cell tests or beginning to use them in screening chemicals.

CONTENTS

Gene Mutation
Historical perspective (Puck); Mutation in CHO cells (Siminovitch); HGPRT mutants in V79 cells (Caskey et al.); Roundtable discussion: Criteria for genetic events

Quantitative Mutagenesis with Rodent Cells
CHO/HGPRT system (O'Neill and Hsie); $TK^{+/-} \rightarrow TK^{-/-}$ assay: In situ results (Moore-Brown and Clive); Assay systems for mutagens and tumor promoters (Chang et al.); Roundtable discussion: Genetic events in quantitative mutational systems

Criteria for Mutagen Screening Systems
Primary hepatocyte cultures and metabolic activation (Casciano); Screening system in regulatory science (Bradlaw); Practical use of mammalian cell assays (Butterworth); A mutagen screening program (Zeiger); Selection of tests (Kier); Regulatory research (Waters); Predictive tests (Krahn)

Analysis of Mutation
Introduction (Ts'o); Membrane transport mutants (Adelberg and Dantzig); Temperature-sensitive mutants and purine-analog resistance (Thompson); $DHFR^{-}$ mutants (Chasin and Urlaub); *aprt* Locus (Taylor et al.); Thymidine-analog resistance (Kaufman and Davidson); Ouabain-resistant mutants (Baker)

Use of Mutagen Screening Systems
Mutagenic gases in mammalian cells (Krahn); CHO/HGPRT statistics (Irr and Snee); L5178Y/TK assay utility (Amacher et al.); Activating systems (Dent); Metabolism and mutagenicity of dinitrotoluene (Couch et al.); Screening with CHO/HGPRT (O'Neill and Hsie)

Human Cell Mutagenesis
Mutagen detection in intact humans and animals (DeMars); Mutagenesis in diploid human lymphoblasts (Thilly); Mutation and DNA repair in diploid human fibroblasts (Maher and McCormick); Mutagenicity testing with PBLs (Albertini); Roundtable discussion: Genetic basis of mutation in human cell systems

Mutation, Cancer, and Progress with Mutagen Testing
Neoplastic transformation (Ts'o); Progress with CHO/HGPRT mutagenesis (Hsie et al.); $TK^{+/-} \rightarrow TK^{-/-}$ assay; Mutant analysis (Clive and Moore-Brown); Evaluation of short-term testing (Hollstein); Gene-tox program (Waters)

Summary (Chasin) **A Perspective** (Butterworth)

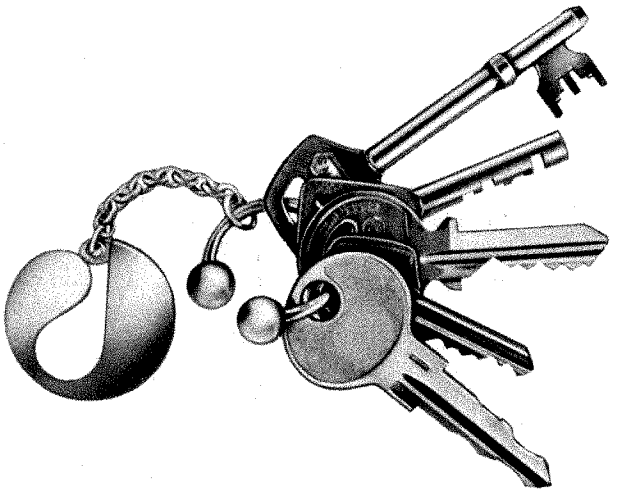
Banbury Report 1
Assessing Chemical Mutagens: The Risk to Humans

Edited by **Victor K. McElheny,** *Banbury Center,* and **Seymour Abrahamson,** *University of Wisconsin*

1979, 367 pp., illus., appendix
Cloth, $38

0-87969-200-6
LC 79-998 CIP

Contents: Introduction; Mutation and Disease in Humans; Strengths and Weaknesses of Tests for Mutagenesis; Bacterial Mutagenicity Testing: Some Practical Considerations; Theory and Design of Short-term Bacterial Tests for Mutagenesis; DNA Repair; Cytogenetic Studies and Risk Assessment for Chemicals and Ionizing Radiation; Radiation-induced Cancer; Low-dose and Species-to-Species Extrapolation for Chemically Induced Carcinogenesis; Estimating Radiation-induced Genetic Disease Burdens; Risk Assessment of Ethylene Oxide and Other Compounds; Dosimetry of Alkylating Agents; Are Benzene Effects Limited to the Chromosomal Level?; General Aspects of Comparative Mutagenesis; Discussion; Summary



Forthcoming 1979 Meetings...

Toward a Less Hazardous Cigarette
Human Health Data from Defined Populations
Ethylene Dichloride: Economic Importance and Potential Health Risks

Innovation: what's in a word?

There is a certain familiarity to British observers in the set of proposals announced last week to stimulate technological innovation in US industry. "Generic technology centers", based at universities and partly supported by industry, have been an active element of Science Research Council policy for several years. Close university/industry links are already enshrined in the SRC's teaching companies scheme and the now flourishing cooperative awards for science and engineering (CASE) fellowship programme. The National Research Development Corporation will be pleased to learn that the US proposal to establish a network of state and regional corporations for innovation development are partly based on its "successful", example — and there will even be annual "President's awards to industry" similar to those bestowed by the Queen on British industry for over a decade.

In Britain, these various developments have taken place in a piecemeal fashion over a number of years, a gradual process of moulding government intervention in the process of technological development, with increasingly important implications for research policy. In the US, they have been put together into a single package which President Carter referred to as a "first step" in supporting industrial innovation as a spur to international competitiveness and domestic entrepreneurship. And also included in the package are a complex set of legislative and administrative proposals ranging from anti-trust rules to technical information services.

The advantage of such packaging is that it provides a central theme around which otherwise disparate activities can be arranged — and Dr Frank Press, the President's Science Adviser, who initially proposed the studies leading to last week's proposals, points out that one immediate effect has been a heightened awareness of the concept of innovation within the administration. The problem, however, is that innovation itself is a slippery concept that is almost impossible to define. And any claim that it is going down (or even up) can only be made on indirect evidence, such as measurements of productivity, or the level of research and development budgets.

Successful innovation, like invention or creativity, cannot be legislated for. The best that can be done is to identify what are considered to be the key variables, and manipulate them in what is considered an effective way. This is partly a matter of technological and economic analysis. But it can also mean the insertion of political or value judgements necessary to short-cut the analysis and make policy decisions possible.

The danger here is that in the absence of hard data, powerful mythologies may be introduced — and subsequently planned for — to legitimate broad-based policy initiatives. In the UK, one such mythology has been to blame a recalcitrant labour force as the major force obstructing innovation, when in practice the problem is part of a complex of domestic and international processes. Poor labour-management relations may well be a part, but other factors, such as international competition and sky-rocketing energy costs, are just as much to blame.

In the US, there is another myth, that of a lost Yankee ingenuity, the Holy Grail often quoted as the main cause of economic strength and technological superiority, now dimmed by a rising tide of regulation. The problem is that a number of sectors of US industry can be identified — electronics, pharmaceuticals, and biotechnology in general might be quoted as typical examples — where innovation (and profitability) are very far from dead. And again there are external factors, in particular the growing strength of Japan and Germany as technological powers, which may give the appearance of US decline, but can provide only relative rather than absolute measurements.

Certainly the US economy is not as strong as it might be. And declining productivity is an important contributor to double-digit inflation. But there are dangers in reducing the problem to a purely technical one, in particular since this may divert attention from other, equally important, aspects of technological change.

Three of these aspects may be mentioned. The first is the impact of technology on the natural and social environment. Regulation needs to be placed on a rational basis if it is effectively to achieve its intended purpose. In practice, levels of regulation are increasingly being set as the balance of economic against social goals, with the emphasis being shifted back to the former — and this form of rationality speaks less of enlightenment philosophy than of political pragmatism.

The second aspect is the impact of technology policy on developing countries. The United Nations Conference on Science and Technology for Development, held earlier this year in Vienna, drew attention to the ways in which the conditions set by the developed countries for the exploitation of knowledge — for example, on patent and licence policies — can affect the Third World's development prospects. Yet there was virtually no consideration of this particular problem within the US innovation review and the subsequent presidential proposals.

Finally, there are the effects of technological change on the labour force. President Carter, stating that labour's main interest is in early warning about changes, is planning a new labour/technology forecasting system to predict the consequences. But there are many predictions that some aspects of innovation — and in particular the structural unemployment that may well result from the increasing automation of production — will be severe, and that more than advance warning may be necessary.

The Kemeny Commission on the accident at Three Mile Island has warned of the danger of concentrating so hard on the adequate performence of mechanical systems that one fails to pay sufficient attention to the gaps and shortcomings in the social systems which support them. It would be a pity if the current concern with technological innovation were to lead policy-makers further in the same direction. □

End nuclear complacency — 3 Mile Island Report

"The US Nuclear Regulatory Commission is currently unable to produce an acceptable level of safety for nuclear power" says John Kemeny, Chairman of the President's Commission on the 3 Mile Island Disaster. **David Dickson** reports on the Commission's findings that human failures led to the escalation of what might have been a minor incident into a major disaster

President Carter visits the TMI control room. At the height of the collapse 100 alarms were ringing

THE public inquiry into last March's accident at the Three Mile Island nuclear plant has resulted in a damning indictment of official attitudes towards the safety of nuclear power.

In its final report, presented to President Carter last week, the 12-member commission which carried out the inquiry strongly criticises the nuclear industry for underplaying the risks associated with the operation of nuclear power plants — and the Nuclear Regulatory Commission for failing to apply adequate controls.

The industry has taken comfort from the commission's final decision — agreed despite a number of closely contested votes — not to recommend a moratorium on the construction of new plants until some of the inadequacies which the report identifies have been put right.

But it has not seriously questioned the commission's major finding: that "fundamental changes" are necessary in the organisation, procedures and practices of both the industry and the NRC if similar accidents are to be prevented in the future, and the risks of nuclear power are to be kept within "tolerable limits".

The commission's report is particularly critical of what it calls the "mindset", widely propagated by industry, that nuclear power plants are basically safe. "The Commission is convinced that this attitude must be changed to one that says nuclear power is, by its very nature, potentially dangerous", it states.

The report also points out that the operating company, Metropolitan Edison, failed to change any instructions to its operators following a similar accident which had occurred at another plant in September 1977, despite strong recommendations for making this change by a senior engineer from Babcock and Wilcox.

The report demands wide-reaching changes in the training of both plant operators and managers, expressing concern at the relative neglect of human factors in nuclear safety. The commission says this neglect is itself a product of a "mindset" preoccupied with the safety of equipment, rather than the ability of operators and management to respond to an emergency.

Other recommendations passed to President Carter include proposals that future reactors should be located "in areas remote from concentrations of population", rather than merely using the concept of "low population zones"; that the NRC be reorganised, with a single director replacing the current five commissioners; that an oversight committee on reactor safety be established of up to 15 people from a range of backgrounds to monitor all aspects of the risks of nuclear power; and that a utility applying for an operating licence must show that the state in which its nuclear plant is to be situated has an officially-approved emergency response plan.

How it happened

The report provides a graphic description, based on evidence received over several weeks of public hearings, of how the events unfolded that led to the worst accident in the history of the US nuclear programme. And the description also reveals how human action — and inaction — transformed a series of minor technical failures into a disaster.

According to the commission, the triggering event was a "fairly routine malfunction" in the equipment which purifies the water condensate from the steam turbine inside the plant. The turbine atuomatically stopped, soon followed by the automatic shut-down of the reactor.

To prevent the water pressure inside the reactor vessel from increasing, a pilot-operated relief valve opened automatically; however when the pressure dropped again, the valve failed to close — allowing the coolant water to escape.

Events built up rapidly from there. Confusion over indicator lights led the operators to believe that the valve had closed. A high-pressure injection system came on automatically; but the operators thought this was filling the plant too quickly with water, and cut the flow from 1000 to 100 gallons a minute. The net result of the sequence of events that followed was that the reactor core gradually became uncovered — leading to eventual fears of a core melt-down.

The human failures attract the particular attention of the Kemeny Commission, since without these, it suggests, the accident would have been far less significant. The specific problem was a failure to recognise the actual conditions of the plant; but it relates these to much wider problems of competence, background and training of both operators and management.

"As the evidence accumulated, it became clear that the fundamental problems are people-related problems not equipment problems", the report states. "We do not mean to limit this term to shortcomings of individual human beings — although those do exist. We mean more generally that our investigation has revealed problems with the 'system' that manufacturers, operates and regulates nuclear power plants."

Some of these failures are listed in detail in an analysis prepared by commission staff on the selection, training, qualifaction and licensing of operating personnel. This report points out, for example, that there is no minimum eligibility requirements for operators laid down by the NRC for factors such as education, experience, reliability, or psychological fitness.

Although operator examinations were consistent with regulations, it says, they did not ensure that candidates for a licence had an in-depth knowledge of nuclear reactor theory, design and operation. Training for operators concentrated on systems, equipment and procedures rather than basic scientific and technological concepts, such as thermodynamics, enthalpy, decay heat production, or solid system operation.

(A spokesman for General Public Utilities Corporation responsible for

0028-0836/79/450120-02$01.00

©1979 Macmillan Journals Ltd

running the plant defended their operators' competence by pointing out that over the period 1975 to 1978, TMI control room operators ranked ninth out of 30 facilities in NRC examination performance; commission members say that this merely indicates the size of the problem.)

Another failure is shown up by the short sentence "utility management did not require attention to detail as a way of life at Three Mile Island." The report goes on to list 23 instances, ranging from relatively minor deficiencies in control room practices to major short-comings in failing to correct faulty equipment, or to identify a group with special responsibility for acting on safety concerns raised by employees.

It also raises major questions about the quality control of important components. For example the report points out that although the operating company, Metropolitan Edison, has a quality assurance programme meeting NRC requirements, these did not apply to the plant as a whole, but only to systems classified as 'safety-related'.

The valve which stuck open, was not classified as 'safety-related'. "In addition, the NRC did not require the level of independent review normally found in the quality assurance programmes of safety-critical industries", the report says. Nor did Met Ed go beyond NRC requirements in applying quality controls to equipment such as radiation monitors or control rod drive mechamisms.

It was therefore a combination of poorly prepared operators and management, plus a lack of attention to relatively minor safety details, that made an accident such as that at Three Mile Island "eventually inevitable" says the report. "Large-break accidents require extremely fast reaction, which therefore must be automatically performed by the equipment. Lesser accidents may develop much more slowly and their control may be dependent on the appropriate reactions of human beings", it says.

Basic flaw

Scientists and engineers had worried for decades about the safety of nuclear equipment, but their approach to nuclear safety had a "basic flaw", namely a preoccupation with large-break accidents, and the attitude that if they could be controlled, it was not necessary to worry about the analysis of "less important" accidents.

"This was the tragedy of Three Mile Island, where the equipment failures were significantly less dramatic than those that had been thoroughly analysed, but where the results confused those who managed the accident."

Another problem, says the report, was that information about conditions inside the plant was not presented in the control room in a clear and understandable form. At one point, soon after the valve had stuck open, there were over 100 alarms ringing in the control room, with no system for indicating which way was most important.

Among the other findings of the commission were:

- Health effects: The commission says that the most serious health effect of the accident was severe mental stress, this being highest among those living within 5 miles of the plant, and in families with pre-school children.

Since most of the radiation was contained within the plant — it calculates less than 0.01% of the radioactive iodine released from the fuel escaped into the environment, and that no detectable amounts of caesium and strontium escaped — the health effects of the accident would be minimal. The commission says it can be "practically certain" that there will be less than 10 extra cancer deaths in the 325,000 people living within a 50-mile radius, and that it is highly likely there will be no extra deaths.

- Costs: The commission estimates that, discounting health costs, the cost of the accident will be between $1 billion and $2 billion, much of this being the cost of replacement power. If the plant can not be put back into operation, the cost will be much higher, it says.
- Seriousness of accident: Examination of several different scenarios that could have taken place included some which would have resulted in a "melt-down". Under this scenario, the fuel would reach such a temperature that it would melt through the steel reactor vessel and reach the floor of the containment building, where its heat would be dissipated by water.

The commission calculated that even if a melt-down occurred, there was a high probability that the containment building and the hard rock on which it is built would have been able to prevent the escape of a large amount of radioactivity. But it points out that, since the calculations are at the limits of engineering knowledge, they include a degree of uncertainty.

- Public and worker health and safety: The commission says that there is inadequate knowledge of the effects of low levels of ionising radiation, of strategies to mitigate the health hazards of exposure to radiation, and of other areas relating to regulation setting to protect health and public health.

It points out that state organisation in Pennsylvania did not have adequate resources for dealing with radiation health programmes relating to the operation of Three Mile Island. And that the utility was not required to, and did not, keep a record on workers of the total work-related plus non-work related radiation exposure.

It recommends more emphasis on research on the health effects of radiation co-ordinated under the National Institutes of Health, as well as an increased programme for educating health professional and emergency response personnel in the vicinity of nuclear power plants.

- Nuclear Regulatory Commission: The report spells out in detail criticisms of the shortcomings of the NRC in dealing with the accident, in particular its apparent indecisiveness, and uncertainties in diagnosing the situation inside the plant. It points out, for example, that NRC officials wrongly concluded on the second day that there was a danger that a hydrogen bubble in the reactor vessel might explode through contact with oxygen produced through water radiolysis, which other scientists later pointed out was impossible.

One of the main conclusions of the commission is that the NRC should be restructured. "The totality of our findings is that no-one is running that particular agency."

'Bark worse than bite'

Reaction to the Kemeny Commission's report has been predictably diverse. Nuclear critics argue that the report does not go far enough in following through the logic of its own conclusions, and that the report's bark may therefore turn out worse than its bite.

"We are still left with the problem of the 70 plants that are already operating in this country, many of which should be temporarily shut down until adequate safety can be guaranteed. We need a whole new approach to the safety of our nuclear programme which goes far beyond administrative juggling", says Professor Henry Kendall, professor of physics at the Massachusetts Institute of Technology, and a co-founder of the Union of Concerned Scientists which has been criticising federal safety measures for several years.

The nuclear industry, carefully sidestepping some of the stronger criticism in the report, has interpreted its message as "proceed with caution" — and points out that it has already been doing much to improve safety procedures following the accident.

"It is evident that the commission found nothing in the wake of TMI that suggests that nuclear power plants as presently designed and built are unsafe," says Darl Walske, president of the industry-sponsored Atomic Industry Forum.

But conventional attitudes — the "mindset" referred to by the Kemeny Commission — retain a strong grip. Three weeks ago the *Washington Post* carried a two page advertisement in which Dr Edward Teller claimed "I was the only victim of Three-Mile Island", since he suffered a heart attack resulting from strenuous efforts to answer anti-nuclear critics; the main lesson of the accident, he said, was that "nuclear reactors are even safer than we thought".

Last week NRC commissioner Peter Bradford wrote to the newspaper accusing Dr Teller of misleading the public — and pointing out that the advertisement had been paid for by the firm which produced the valve which had stuck open at Three Mile Island. □

Nature Vol. 282 8 November 1979

US boosts university-industry links

After 18 months' study by the Commerce Department, President Carter last week made 32 proposals for increasing the commercial exploitation of scientific knowledge. **David Dickson** reports.

PRESIDENT Carter is demanding that federal agencies substantially increase their efforts to stimulate links between the university research community and private industry. Building on the recent experience of the National Science Foundation, he has recommended that the government raise its support for such efforts by $150 million a year.

The recommendation is one of 32 which the President made last week in a message to Congress on new initiatives to stimulate industrial innovation.

Describing the package of recommendations, the fruits of an 18-month study by the Commerce Department, as a "first step" towards meeting the nation's commitment to innovation, he said they would help "the continuing challenge to maintain the economic strength of the US economy."

The review was initially recommended by Dr Frank Press, director of the Office of Science and Technology Policy. Its basic premise was that many of the nation's economic problems can be related to a decline in the rate of productivity; and that this in turn has been partly caused by a decline in innovation, as implied by factors such as declining investment in research and development and a decrease in the number of patent applications.

Many of the President's recommendations directly involve research. Yet rather than concentrate on ways of increasing direct federal support for research of interest to industry, the President's recommendations focus instead on the environment in which both research and innovation take place — and thus how the government can alter this environment to make it more conducive to economic growth.

The review therefore covered all aspects of the innovation process, from anti-trust policy to technical information systems, making numerous proposals for legislative and administrative changes. In the short-term, however, a principal beneficiary of the review is likely to be the National Science Foundation, budgeted to receive about $30 million of the extra $55 million which the President suggested needs to be spent in 1981.

The purpose of the NSF money will not primarily be to support further research — although this will obviously be one effect — but to open up the arteries connecting universities to private corporations. In this way it is intended to help to lead to what Secretary of Commerce Mrs Juanita Kreps referred to as "a more effective partnership among government, industry, labour, and the academic community."

In particular, the NSF's budget request for 1981 will include a three-fold increase in support of a programme introduced last year to finance research proposals jointly submitted by university and industry research workers. NSF officials points out that the programme, scheduled to increase from $8 million to almost $30 million, has already attracted the involvement of major corporations such as Westinghouse, Union Carbide and Monsanto.

President Carter has now suggested that the NSF experience be used as a test-bed for cooperative projects sponsored by other federal agencies, such as the Department of Defense, the Department of Energy and the Environmental Protection Agency, and that an aggregate target of $150m be eventually aimed for.

Furthermore in view of the historical importance which small entrepreneurial firms have played in bringing new products to the market-place, he is proposing to increase the budget of the NSF's Small Business Innovation Research Programme from $2.5 million to $10 million. Again this would be used as the basis of a $150 cross-agency effort.

"The innovation review makes clear

The new innovation initiatives in detail

SOME of the main initiatives announced by President Carter to spur industrial innovation in last week's message to congress:

●Four "generic technology" centres will be established at universities and other private sector sites to encourage research and development in fields such as corrosion prevention, automated assembly, and tribology. Each centre will be jointly financed by industry and government, with the latter's share dropping to 20% or less by the fifth year. Three centres will be established in 1981 by the Department of Commerce, and one by the National Science Foundation, at a cost of about $6 to $8 million.

●The NSF will receive an additional $20 million in 1981 to increase its efforts at linking industry with university scientists. The foundation will also work with other agencies to initiate similar cooperative R&D programmes, with an eventual aggregate target of $150 million.

●The federal government will seek legislation to establish a uniform patent policy. Under this legislation, title to a patent resulting from federally-funded research would be retained by the government, but contractors would obtain exclusive licenses in specified fields of use. Small businesses and universities, however, would be allowed to retain patent ownership "in recognition of their special place in our society"

●The Department of Justice will clarify the role of anti-trust legislation with respect to research collaboration between different companies

●The NSF's Small Business Innovation Research programme will be expanded from $2.5 million to $10 million in 1981. The foundation will help other agencies develop similar programmes, under the co-ordination of the Office of Management and Budget, with an aggregate target of $50 million

●Increased assistance will be provided to establish Corporations for Innovation Development (CIDs) on a state or regional basis, to help entrepreneurs gain access to investment capital

●To help minimise the impact of regulation, executive health, safety and environmental regulatory agencies wil prepare five-year forecasts of their priorities and concerns. "Better knowledge of agency plans will allow industry to plan its research and development" says the administration

●In addition, federal executive agencies responsible for reviewing the safety and efficacy of products will develop and implement a system of priorities. Under these systems, the agencies will identify those products that are most innovative and/or have exceptional social benefits, and expendite their clearance reviews "to the extent permitted by applicable statuttes"

●The Secretary of Labour and the Secretary of Commerce will work with labour and management to develop a national Labour/Technology Forecasting System. This system would develop advance warning of industrial changes and permit timely adjustments

●The Commerce Department and the NSF will host a national conference for deans of business and engineering schools to stimulate improved curriculum development in technology management and entrepreneurship

●The National Technical Information Service will establish a new center, at an annual budget of up to $2 million, whose purpose will be to improve the flow of knowledge from federal labortories and R&D centres to private industry

●The President will establish an annual award for technological innovation in the six areas of transportation, communication, health, agriculture and food, and natural resources (including energy). The awards will be presented by the President's science and technology adviser. □

0028-0836/79/450122-02$01.00

©1979 Macmillan Journals Ltd

how extensively innovation depends on R & D, especially on long-term research. But the expertise in universities has not been used as extensively as possible to support industrial innovation. The NSF programme has already shown successes, and it is time to expand this effort," says Dr Press.

Congressional response to the package, promised since last April, has been lukewarm. Some proposals, such as the setting up of "generic technology centres" and the introduction of uniform patent policy, have been generally welcomed; indeed many are already part of legislative proposals currently before Congress.

At a Senate hearing last week, however, several Congressmen criticised the package for not including any tax incentives related to R & D expenditures. Administration officials replied that these would come later, as part of a complete set of tax reforms; and Dr Jordan Baruch of the Commerce Department said that tax incentives might not be a sharp enough instrument to attack such a complex issue.

Senator Adlai Stevenson criticised the package for lacking imagination. "It is a first step, but I am not convinced that the Executive Branch has got the guts to take the next ones needed to reach a rational technology policy" he said. Mr Stevenson quoted in particular Japan's recently announced plans to stimulate government support across a wide range of technological areas, from ocean mining to integrated circuits.

"For 25 years the question of innovation has been around," replied Dr Press. "For the first time the President has come forward with definite proposals; I think this is an important step. And US industrial leaders that I have spoken to would not want to touch what the Japanese are doing with a ten-foot pole." □

Soviets announce build-up to fusion power

RECENT Soviet developments in energy were conspicuous by their absence from the agenda of last week's UK-Soviet energy symposium in Moscow. To some extext, this was to be expected, since the prime aim of the symposium was to explore areas of possible cooperation in the near future. Nevertheless, even in his exposition of the long-term "second stage" of the new Soviet energy "strategy", the Minister of Power and Electrification, Peter S. Neporozhnyy, made no allusion at all to the Soviet Union's latest step in power generation — the start-up of the first module of the Angara-5 fusion generator.

This is all the more remarkable since the demonstration run of the Angara-5 module, early in October, was given considerable media coverage for both home and foreign consumption. The Angara-5 is an electron beam device, the name, according to *Pravda,* signifying the five tributaries (the beams) which flow into lake Baikal (the tritium/deuterium target), and issue thence as the mighty Angara river (the energy produced). Last month's test of the module was carried out at the Kurchatov Atomic Energy Institute; according to Valerii Legasov, the Deputy Director, after "through experiments" have been carried out with each of the 48 modules, a "demonstration" Angara-5 will be built at the institute's test site.

No indication, has so far been given of when the break even point may be expected, although Moscow radio's "World Service" suggested that the first power plants based on Angara-5 will be built by the end of the century. At all events, practical use of the Angara-5 lies too far in the future to merit a place in Neporozhnyy's "strategy", although his outline of the "second stage" did include some references to MHD and fusion generation.

In MHD, he said, work would go forward on improving conversion efficiency and hinted that "energy and magnetic field parameters close to commercial" were already within reach on one experimental device. Fusion research, he said, would continue using both Tokamak and laser techniques. Already plasma temperatures only 4-5 times less than those required for sustained reaction, he said, had been attained.

The majority of the symposium, however, was devoted to the first stage of the strategy; development of the coal industry, including low grade coals to be used in generating stations close to the mines, expansion of the Siberian hydroelectric network and the phasing out of oil and gas-fired power stations.

Although the Soviet planners still claim ample reserves of oil and gas, they are now ready to admit that these lie in increasingly remote and extreme terrains, and that exploitation costs will become increasingly expensive. Indeed, for the firt time, they are prepared to admit small and temporary stortfalls in production. In the not too far future, the Soviet participants in the symposium agreed, oil will have to be reserved for oil-specific industries — transport and petrochemicals.

Nuclear generation will to a large extent replace oil in the power sector. Although the extension of the Union-wide "supergrid" of 1500 V DC transmission lines should, theoretically, allow power stations to be sited anywhere, the old paradox of the Soviet energy map (80% of resources east of the Urals, 80% of consumption west of the Urals) is being perpetuated in the siting of future nuclear power stations, close to the consumers.

Hardly a mention, even in informal discussions, was made during the symposium of Academician Sollezhal's recent proposals for nuclear generating "complexes" in Siberia. The safety and ecological aspects raised by Dollezhal' were barely alluded to, and the plans for nuclear "boiler houses" for district heating in major cities were given great prominence; with, perhaps, one small difference.

Until now, Soviet commentators have suggested that the nuclear boiler houses would be situated in the suburbs of the cities, with a "safety-zone" of some 1-2 km around them, reserved for industrial and leisure use (but not housing). Now, however, according to Neporozhnyy, the boiler houses may be further away — transmission of the hot water for up to 50km, he said, is reckoned to be "economic". **Vera Rich**

Hungarian reactor to be made 'safe'

CONSTRUCTION of the Paks nuclear power station, which should supply one third of Hungary's present peak power demand, is at last on schedule. Last year, the station, whose construction had been running late since 1975, was the subject of special resolutions by the Council of Ministers and the Party Politburo. A new management system was set up, with government commissioners working on the site. Shortly afterwards, building operations were reported to have "speeded up considerably', although the workforce of 5200 is still insufficient and more managerial changes are envisaged if the original schedule is to be maintained.

This acceleration, however, has not been achieved at the cost of safety. Out of the 60,000 million forints (£1,500 million) which the station will cost, 12,000 million (20%) will be spent on safety measures.

The Hungarian planners are in a somewhat delicate position as regards safety. The country is small, with no convenient expanse of empty land in which to site a reactor. Moreover, Austrian TV reaches considerable areas of Hungary, and although any evidence on the subject can only be anecdotal, there is good reason to believe that the population at large was considerably perturbed by the "anti-nuclear" verdict of the Austrian referendum earlier this year.

Perhaps for this reason, a recent Budapest TV programme describing the Paks station paid especial attention to its safety precautions. "Triple walls", said the commentator, separate radioactive materials from the environment. The outermost of these walls, from his description, is simply a steel and concrete containment vessel — of the type, until recently, dismissed by Soviet planners (who are intimately involved in any Comecon nuclear power station) as a Western capitalist ploy to inflate costs. □

EPA panel recommends postponement of 2, 4, 5-T hearings

THE herbicide 2, 4, 5-T poses no "substantial hazard to human helath or to the environment" according to a report prepared by the Scientific Advisory Panel of the section of the US Environmental Protection Agency concerned with the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA). Accordingly, the panel recommends that the final hearings to consider the validity of the ban on 2, 4, 5-T be postponed until more information on the carcinogenicity and reproductive toxicity of the herbicide and its 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (dioxin) contaminant is available.

The EPA enforced a ban on the use of 2, 4, 5-T in March of this year following a study in the state of Oregon which linked an increase of spontaneous abortions in the area to spraying with the herbicide (*Nature* 8 March, page 108). The initial ban was restricted to use of the herbicide in forestry but since then has been made total and applies to all applications of 2, 4, 5-T.

Law Court and EPA hearings have been held at intervals since March to consider the merits of the ban. The final hearings, initially scheduled for October 1979 have been postponed until January 1980 and if the advisory panel has its way will be postponed even longer.

The panel's report is based on evidence presented by interested parties at two open meetings held during the summer. Following the meetings, the panel agrees that the EPA is correct in stating that 2, 4, 5-T and dioxin are teratogens and fetotoxins. It also takes the EPA view that as dioxin is carcinogenic in test animals it may be a "potential human carcinogen."

But the panel disagrees with the EPA's opinion that human exposure "from spray drift and the water environment is likely to be broad or substantial" where 2, 4, 5-T use on rice is concerned. As for the use of the herbicide on rangeland the panel says there is no "convincing argument of an immediate or substantial hazard" to humans.

Dow Chemical Company is the major producer of 2, 4, 5-T in the US and stands at the forefront of the campaign to have the ban on 2, 4, 5-T lifted. The company insists that there is no good scientific evidence to support the ban. Dow scientists admit that dioxin is extremely toxic but state that it is not present in sufficient concentrations to pose a human health hazard.

The Advisory Panel points out that on some questions the EPA position is "relatively close to that of the scientists from the Dow Chemical Company". In contrast to the view put forward by the EPA that there is no safe level for dioxin in rats and mice the panel says that such a statement is incorrect. And it suggests that a review of the evidence shows that the EPA and Dow Chemical are not as far apart on this issue as it might seem.

It remains to be seen whether this internal vetting process will have any influence on the EPA's actions on 2, 4, 5-T. The results of the report will give a considerable boost to Dow's campaign and the company for public relations reasons, may well agree with the final recommendations of the panel, that in view of the potential toxicity of dioxin "efforts should be made to further reduce" its level in commerical preparations of 2, 4, 5-T.

Alastair Hay

Pathogens panel should have lay representation, says UK health minister

THE new Conservative government, like its predecessor, is taking into account the recommendations of the Shooter Report on the outbreak of smallpox in Birmingham last year in drawing up new regulations for the safe handling of dangerous pathogens during research work and diagnosis. Mr Patrick Jenkin, Secretary of State for Health, told a meeting organised by the Association of Scientific, Technical and Managerial Staffs (ASTMS) in London last week, that the government is planning to implement many of the Shooter recommendations and also some of those made by the Health and Safety Executive in its recent publication 'Dangerous Pathogens: draft regulations and draft guidance notes'.

Under the government's new proposals, notification of intention to work with category A pathogens (the most dangerous) would be compulsory, said Mr Jenkin, and laboratories would have to be inpsected by HSE inspectors before work could begin. They would then have to be inspected regularly against a checklist which is to be drawn up in accordance with recommendations laid down by Shooter. Laboratories researching with category A pathogens would also have to be sited outside densely populated areas.

The government has set up a panel which is currently looking into the workings of the Dangerous Pathogens Advisory Group (DPAG), a committee of experts currently under the auspices of the Department of Health and Social Security (DHSS) which was set up in 1973 to administer a system of voluntary control of work with category A pathogens. According to Mr Jenkin, the panel is likely to recommend that a new body be set up with an expert and lay membership, including professional, trade union and public interest representatives. This body should remain under the aegis of the DHSS and would administer the new compulsory system of notification.

The position with public health laboratories is different because they are mainly concerned with category B pathogens which do not have to be notified to DPAG. There could come a time, however, said Mr Jenkin, when notification for category B pathogens would also become compulsory. Nevertheless, he assured the meeting that it is still the government's intention to implement within three years the recommendations for improved safety in public health service laboratories laid out in the Howie report published last year. "It would inevitably cost the National Health Service a lot of money to bring all its labs up to the standard of the Howie report", he said, but the government thought that the £7 million (1978 prices) needed could be found.

Clive Jenkins, General Secretary of ASTMS, agreed with the opening up of membership of DPAG to non-experts. "Free standing committees of experts are things of the past", he said and added that a body along the same lines as the Genetic Manipulation Advisory Group (GMAG) would be appropriate: "GMAG has worked as well as is possible for a voluntary body to work". Nevertheless he thought that the Health and Safety Executive would be a much more appropriate body than the DHSS to manage DPAG's affairs. "We want everyone to know the dangers of the leaky labs", he said.

Patrick Jenkin: reforming DPAG

Dr Roger Nourrish, microbiological inspector with the HSE, told the meeting of his visits to research and diagnostic laboratories designed to handle category A pathogens. Of the research laboratories, those at Reading and Paddington had stopped work before the HSE's visit, those at Purbright and Elstree were asked to stop work after the visit until improvements could be made and those at Porton Down and Liverpool were asked to make some inprovements while still remaining operational.

news in brief

US Supreme Court to rule on whether living organisms can be patented: The US Supreme Court agreed last week to rule on whether patents can be granted on living organisms. The case concerns two patent applications initially rejected by the US Patent Office, but subsequently granted by an appeals court. The patent applications have been filed by research scientists with the companies General Electric and Upjohn respectively; one is for an organism which is capable of breaking down oil spills, the other for a bacteria to produce the antibiotic lincomycin.

The Patent Office, supported by the Department of Justice, contends that living organisms are not covered by current US Patent Law; in support of its claim, it quotes the fact that Congress felt it necessary to pass a separate act to allow the patenting of plants. The Appeals court, however, agreed with the applicants that what was being requested was patent protection for a novel chemical process, and that this comes within the scope of the law as it is now written. In contesting the appeals court ruling to the Supreme Court, the Department of Justice argues that the economic implications of the ruling "are very significant, given the vast area that it opens to patentability."

MIT joins banking firm to study commercial aspects of applied genetics: The Massachusetts Institute of Technology announced last week that it had received a grant of $50,000 from the US Congress' Office of Technology Assessment to co-operate with the New York banking and investment firm F Eberstadt and Co to look at the industrial and commercial aspects of applied genetics. The purpose of the grant, which will be administered through MIT's department of nutrition and food science, is to provide OTA with data for providing Congress with policy options on regulation, taxation, patent protection and research funding in the food, chemical, and pharmaceutical industries that develop and market new products and processes from living cells.

In annoucing the grant, MIT said that after completion of the study, it was planned to hold a seminar for academic and industrial scientists and engineers, and for investors on the development of the industry under study. Five aspects of the industry will be covered in the study: historical development, current and predictable state of the art of various genetic technologies, research efforts in the development and applications of these technologies, and assessment of technical, institutional, economic and social factors that could affect the rate of adoption of these technologies.

French committee formed on recombinant DNA technology: A committee for information on genetic manipulation held its first public meeting 22 October at the Museum of Natural History in Paris. The meeting stressed the need of not acceding to what it called "the giddiness of biologists" and to the "fascination that genetic manipulation exercises on its practitioners". The committee hopes to call attention to the risks inherent in the new technology and to "the great laxness that exists in the definition of health and safety regulations in the area". The Secretary of the group is Jean Deutsch of the Genetic Research Group of the University of Paris VI.

Fewer US physicists means better job propects: The employment outlook of US physicists is improving, according to a study published by the physics manpower panel of the American Physical Society. In an extensive survey of immediate past and future employment prospects for PhD physicists, the panel says supply is beginning to approach demand, and it concludes that "the physics community, taken as a whole, has passed through its gravest hour."

However the panel goes on to warn that the prime reason the job market is beginning to look healthier for new entrants is that there are so few of them. "There will continue to be imbalances between many components of supply and demand", it warns. According to statistics prepared for the panel, the probable number of physics doctoral graduates will coincide with the total demand — assuming a 1 per cent annual growth in the table — around 1984. *"The Transition in Physics Doctoral Employment 1960-1990"*. The American Physical Society, $5.00.

Salam gives Nobel prize money to fund Third World Science: Professor Abdus Salam, co-winner of this year's Nobel Prize in Physics has pledged his share of the prize money — $60,000 — to an international talent fund for young scientists. Speaking at a meeting of the Executive Board of UNESCO, Salam urged increased support for Third World science training because of the failure of the UNCSTD talks last August in Vienna. The developed nations, at Vienna, were asked to contribute $2bn to aid research but had offered only one seventh of that.

Indo-Soviet scientific cooperation to expand: Indo-Soviet cooperation on science and technology will soon cover several new areas. Russia will share with India its experience and technology in earthquake prediction, laser applications, semiconductors and systems analysis over three years beginning 1980, according to a decision taken by the Indo-Soviet subcommission on science and technology which met at Moscow in the second week of October. The areas identified for cooperation in basic sciences are crystallography, low temperature physics, chemistry of natural products, microbiology and radio astronomy. The subcommission will meet again in February 1980 at New Delhi to finalize the objective in each area, time schedule and the participating laboratories.

The two sides have also decided to continue cooperation in alternative sources of energy, MHD generators, metallic corrosion, powder metallurgy, meteorology, low-cost housing, construction technology, scientific and technical information systems, machine tools, and water resource management. Earthquake prediction was included at the insistence of Professor M G K Menon, the leader of the Indian side, since the excellent system developed by the Soviet scientists for predicting and identifying the epicentre of an impending earthquake is of great relevance to the quake-prone Indo-Gangetic plain and eastern India. — *S. Arunachalam.*

Michigan PBB suit settled out of court: The Velsicol Chemical Corporation has made an out-of-court payment of $2.6 million in damages to 70 Michigan farmers who filed suit against the company after buying animal feed which had been contaminated by polybrominated biphenyl (PBB). Millions of farm animals died or had to be slaughtered as a result of the contaminated feed. Velsicol also agreed to waive the farmers' debts to the farm cooperatives that sold the feed, and the farmers agreed to waive any claims of personal injury. According to Velcisol, the latest settlement clears up half of the property claims against the company. There are still 69 suits outstanding.

French government to start Tricastin 1 reactor: The French government has proceeded with the loading of its Tricastin 1 reactor in spite of the presence of cracks in the tubular collar separating the primary and secondary cooling circuits. The decision follows the one taken last week in which the Gravelines 1 reactor was started in spite of similar cracks. Both reactors had been closed because of militant trade union and community response. At this time the Communist trade union federation the CGT has decided not to oppose the loading while the Socialist federation, the CFDT has temporarily postponed further strike action. In the meantime a civil court in Paris has ruled in the government's favour in a civil suit brought by Friends of the Earth. The court ruled that it was incompetent to decide whether to grant a request by Friends of the Earth to halt the start up until the cracks are repaired or the plates are replaced.

The Asian Institute of Technology celebrates its 20th anniversary this year. David Bousfield and Ziauddin Sardar have visited it recently and have returned with different views on the impact it is making on the regional development of Asia. Here they discuss their impressions.

Could AIT be a model for the Third World . . .

THE role science and technology should play in developing countries may well be epitomised by the approach adopted by the Asian Institute of Technology (AIT) situated in Thailand about 40 Km north of Bangkok.

More than half the world's population live in the countries served by the AIT and for the past twenty years it has been gradually building up scientific and technological knowhow in the developing nations of the East. The recent UNCSTD conferences left many scientists confused as to the role they could and should play in aiding development in the Third World — the example set by AIT may help them and their governments to see a way to help.

The Asian Institute of Technology started life in 1959 as the South East Asian Treaty Organisation (SEATO) Graduate School of Engineering — the brain child of Pote Sarasin, the first Secretary General of SEATO, and a former Prime Minister of Thailand. Intended to provide a source of highly qualified engineers for Asian projects, the school began as a small collection of rooms in the Engineering Faculty of Chulalongkorn University deep in the heart of Bangkok. But it grew rapidly and in 1967 became autonomous from SEATO. Six years later it moved to its present rural setting in a 400 acre campus donated by the Thai government.

Educationally the main emphasis is on a five term master's degree in engineering or science, but PhD's are also an important part of the range of qualifications AIT can offer. At present the institute has 500 students and 62 full-time teaching and research staff. In both cases the range of nationalities is huge but most students are from Thailand itself or neighbouring countries such as Malaysia, the Philippines, Pakistan, India and Bangladesh. 60% of students who receive an AIT qualification return to their own countries to work in industry, government or universities. The institute clearly supplies a 'local' need.

Recently AIT has been gradually shifting from a strict commitment to infrastructural engineering to new fields which directly contibute to the porcess of national development in a Third World context. Areas such as food production, resources management, rural, industrial and urban development have become major concerns. The Divisions of Human Settlements is particularly active in this area and I spoke to Paul Vorratnchaiphan, a research associate, about one of the division's main interests, the Building Together Project.

The continual migration of rural folk to urban areas creates many problems for developing countries. To house people properly will require considerable changes in current low-income housing policy and, consequently, research into developing appropriate low-cost housing technology is needed. AIT is currently supervising a slum resettlement programme involving the rehousing of 180 families at Lad Phrao on the outskirts of Bangkok. The initial land purchase, development and coordination was financed by 'Brot für die Welt', a German organisation, and SELAVIP, a 'popular' housing service based in Chile. By mortgaging the land and completed houses to the Thai National Housing Bank this initial 'seed' money should be sufficient to finance in serial fashion many similar projects.

The main structure of the houses is formed by special interlocking lightweight construction blocks designed by AIT and made from a rice husk aggregate in a cement and sand mix produced on site. The prospective owners, working in groups on clusters of 16-20 houses, manufacturing all the component parts themselves. Each group is broken down into teams making joists, doors, piles or casements, *etc.* Seventeen weeks of part-time work are required from start to finish and by this time many of the previously unskilled owners have learnt their first trade. It is hoped that this will provide some of them with a new source of income and give a better sense of purpose and cohesion to the community.

Other AIT projects include the development of a system using composted human and animal waste as a nutrient source for freshwater algae and, ultimately, fish such as *Tilapia.*

I also spoke to Robert Exell, Associate Director of the Division of Energy Technology. Renewable energy resources are another important focus for AIT's research activities. Drying of crops, fish and meat are all long known applications of solar energy and one recent development is a solar powered rice dryer. This simple device draws air heated by the sun through a closed drying compartment containing the grains. These are protected from the rain by plastic sheeting on a bamboo framework. Half a ton of paddy rice can be dried in one to three days.

The same group has also developed a solar powered refrigerator for storing labile medical supplies in remote areas. AIT, however, hopes that the unit can also be made to provide a source of income for these communities. For example, it could be used to preserve commercially grown flowers during the critical period between cutting and refrigerated export to Hong Kong. AIT is currently collaborating with a local university project aimed at introducing this refrigerator and flower culture into the economies of primitive hill tribes in the north.

I spent a day on the AIT campus and only managed to visit two research wings. In fact the institute has nine teaching and research divisions, these being agricultural and food engineering, computer applications, environmental engineering, geotechnical and transport engineering, human settlements development, industrial engineering and construction, water resources engineering and, the most recent addition, energy technology. Also, the institute is the home of the South East Asian regional computer centre, one of the best engineering libraries in South East Asia, a language and media centre (the language used by the institute is English) and the Regional Documentation Centre.

David Bousfield

AIT's low-cost, appropriate housing for slum resettlement

0028-0836/79/450126-02$01.00

. . . or does the West have too much control?

THE Asian Institute of Technology (AIT) advertises itself as a centre of excellence which "provides opportunities for men and women of diverse Asian nationalities to study and work together to seek, define, and test technological solutions to the common problems affecting the quality of life in Asia". This claim is indeed partly justified; but the institute's impact on Asia, as a whole, has been negligible.

AIT's approach to the problems of Asia is based on the belief that academic excellence can be integrated with teaching and research for appropiate solutions to Asian problems. This approach has largely paid off and AIT can justly claim that its graduates are tailor-made for Asia's needs and that as a post-graduate technological institute it has produced over the past two decades, a small cadre of technocrats that now occupies key positions in Asia's private sector.

On the research front too, most AIT projects are based on problems of practical importance relevant to Asia's development. In their own way, some of these projects, such as integrated farm study, a small scale fishery project, slum settlements and flood forecasting studies, have made significant contributions at local level.

However, from a general regional perspective, AIT's contribution to Asia seems almost insignificant. In 1977, for example, AIT graduates included one graduate from Iran, 7 from Malaysia, 12 from Pakistan, 20 from Sri Lanka and 49 from Thailand. This year, AIT's graduate output included one student from Iran, 9 from Malaysia, 11 from Indonesia, 14 from Pakistan and 16 from Sri Lanka. On this basis of graduate output almost every technological university in the UK can claim to contribute much more to the educational development of Asia than AIT. With the exception of human settlement development, research at AIT too has failed to have a regional impact.

Indeed, both from the point of view of education and research, the chief beneficiary of AIT's endeavours is Thailand. Over one-third of AIT Alumni are Thais. Of the 15 reserch projects started in 1978, nine were related directly to the needs and requirements of Thailand.

AIT has considerable difficulty attracting students. Universities and colleges in many Asian countries do not know of its existence and consequently cannot recommend their graduates to apply for its post-graduate training. Even when a student applies and is accepted, political reasons may prevent him from attending. Most students who can go abroad to study would prefer to go to the West than to AIT in spite of its excellent reputation.

One reason why AIT has not made a significant impact on the region is that, even after twenty years, it is still regarded as an alien body. Even in Thailand, it is looked upon as having been transplanted from the West. In other Asian countries too AIT is thought of as non-Asian. In Pakistan, Iran and Turkey it is hard to find science policy makers at the ministerial level who do not have some reservations about it.

Part of the reason why AIT is labelled as an alien institution is that it is administered and funded largely by the West. Less than half of its 39-member Board of Trustees are Asian, and most of these are Thias with a token Malaysian, Indian, Indonesian and Sri Lankan. Amongst AIT's major backers are IBM, Shell, Esso and Bes Engineering. Other major contributors include Canada, Japan, US, Thailand and the Ford, Rockefeller, Chase Manhattan, Readers' Digest and Starr Foundations.

On the whole, the donors keep a good eye on the institute. Visits by their representatives are frequent. Indeed, as Dr Robert Excell, Associate Director of Energy Technology Division, who has been at AIT almost a decade says, some donors tend to dictate and influence AIT's policy. This trend seems to be increasing and, according to Excell, is a major area of concern for AIT's future. "We must try and remain independent of donor influence in the future", he says.

Donor influence apart, a major future area of AIT's contribution to the region is specialised science information. AIT has an excellent Regional Documentation Centre which was set up in 1977 with the objective of improving access to information in the region and of initiating and participating in information projects on a regional basis. There are also four specialised information centres that have already proved their worth: the Asian Information Centre on Geotechnical Engineering, the International Ferrocement Information Centre, the Renewable Energy Resources Information Centre and the Environmental Santation Information Centre. AIT's Regional Information Centre, together with the four special information centres, could act as a regional focal point for the global information system proposed by UNCSTD (*Nature* 6 September page 4), if AIT can seek out users and meet their needs.

Ziauddin Sardar

US strengthens scientific links with Latin America

Closer scientific links between the US and various Latin American countries are expected to follow a visit made last month to four countries by a top level team of science policy makers, headed by the President's science adviser, Dr Frank Press.

The delegation stressed that the purpose of the visits was directly in line with the agreements reached at the United Nations Conference on Science and Technology for Development in Vienna in August. "I was very pleased with the trip — the response was very warm and positive", Dr Press told *Nature*.

The visit also helped to prepare the ground for US strategy at the annual meeting of the Organisation of American States, which opened in Bolivia recently, at which the US is keen to promote technological and economic cooperation between Latin American countries as a way of promoting political stability on the entire American continent.

During the visits to Peru and Barbados, for example, the US delegation met with representatives of the two regional organisations, the Andean Pact, and the Economic Pact between Venezuela, Ecuador, Peru, Colombia and Bolivia — and the Caribbean Community Secretariat (CARICOM).

During the visit to Peru, the delegation met officials of the Junta del Acuerdo de Cartagena, the secretariat for the Andean Pact, to emphasize its willingness to support research programmes initiated by the Junta aimed at increasing technical collaboration between the five countries (see *Nature*, 12 October 1978).

The delegation's visit to Venezuela was aimed primarily at strengthening scientific links which already exist with the US. Particular attention was paid to proposals from the Venezuelan side on developing cooperation in basic and applied scientific research, particularly in the fields of marine biology, neurobiology, electronics and hydrology.

In Brazil, it was more a question of re-building links that have been strained in recent years. Here the specific topics under discussion included coal liquefaction technology, long-distance energy transmission by superconductors, and establishment of a diagnostic reference centre, as well as industrial technology and inter-university science and technology cooperation.

During the visit to Barbados, the delegation met with representatives of other regional development and research organisations. A communiqué issued after the meeting said that "the two sides expressed satisfaction with the progress made in the limited time available towards establishing a sound basis for science and technology cooperation between the United States and the Carribean". □

Human ingenuity is wasted on nuclear power

SIR,—I rather hoped that "nuclear nonsense" might draw a response from UKAEA. It is not nonsense that fast reactors produce 60 times more energy than thermal reactors. I said in my original letter (13 September, page 98) that it might be true in 200 years' time. Cutts and Smith (18 October, page 522) admit that it could not come about until after all thermal reactors had been replaced by fast reactors, and that on the best figures UKAEA could produce the ratio would only be 1.7 by 2020; so as they do not give a figure of their own, I take it that 200 years is not unreasonable.

What is nonsense is the use of this hypothetical long term ratio of 60 as an argument for developing fast breeder reactors now. It is all the more nonsensical because Granger and Merrick showed that even a delay in starting a fast breeder programme of as much as 30 years would be rapidly made up, because the main limiting factor is the production of plutonium by thermal reactors.

This is implicitly admitted by Cutts and Smith, because having predictably taken my "nuclear nonsense" to refer to the 60 times ratio, rather than Smith's use of it to support the development of fast breeder reactors, they then drop this argument and concentrate on lauding the possibility of eventually reducing uranium imports to zero. On this basis coal would seem to be a clear winner for the medium term, and the long term superiority of conservation plus solar energy over both hardly needs demonstrating.

It is an amazing paradox that nuclear scientists and technologists — even Alvin Weinberg (4 October, page 335) — can claim that human ingenuity is so great that it can deal successfully with all the problems which are associated with Three Mile Island and the 'China Syndrome', in a world dotted with nuclear reactors and repositories of highly radio-active waste requiring protection for thousands of years, a world in which the use of nuclear energy will inevitably be accompanied by the widest proliferation of nuclear weapons. Yet when faced with the job of utilising just one hundredth of one per cent of the energy showered on us by the only safe nuclear power plant — the Sun — human ingenuity flies out of the window, and only the difficulties can be seen. Yet this latter use of human ingenuity is the only one which offers even a glimmer of hope for the future of mankind.

Yours faithfully,

J. W. JEFFERY

Birkbeck College, University of London, UK.

Aflatoxin B_1 in barley in the UK

SIR,—In the United Kingdom in the early 1960s a link between the death of 100,000 turkey poults and the fungus *Aspergillus flavus* was recorded. Further studies identified the toxic entity of the fungus to be aflatoxin B_1, produced in imported groundnut. Further research led to the detection of aflatoxin in many animal and human feeds imported into the United Kingdom, e.g. walnut, pistachio, maize, cotton seed, etc.

Though *A. flavus* has been isolated in the UK, it has been thought either that strains are not capable of producing aflatoxin B_1, or that the substrate and conditions are not conducive to aflatoxin B_1 production. In June of this year, however, a farmer requested advice from Microbiology Department of the Ministry of Agriculture, Wales on the health risk to himself or his stock from mouldy barley. Enquiries found the barley had been treated with commercial propionic acid at an inadequate application level. Further laboratory examinations showed the mould to be *Aspergillus flacus* (5×10^7 prepagules/g barley), while mycotoxin examination gave a level of 125 μg aflatoxin B_1/kg barley.

The detection in a home grown cereal of aflatoxin must be regarded with some concern, because of its known carcinogenic and toxic properties. Also, questions must be asked as to the significance of a chemical additive. Additional studies are to be carried out to place this finding in perspective. We intend to study *A. flavus* isolates from soil and grain in Wales, for their ability to grow in varying concentration of propionic acid, and also, to assess such isolates for aflatoxin B_1 production. The results should help to clarify whether this incident is an isolated case or part of a greater problem.

Yours faithfully,

A. HACKING
N. R. BIGGS

Welsh Office, Aberystwyth, UK.

Cooperation with the USSR

SIR,—I have read the letter from Lee Lorch (13 September, page 98) with great concern. He does not seem to realize that cooperation must be two-sided; to be accepted as an equal partner, the Soviet Union must treat all its nationals on an equal footing.

Admittedly, the West may lose as much as the USSR by reduction of cooperation. But what other way is there of protesting against the way that the USSR is treating its Jewish scientists?

Yours faithfully,

H. LIPSON

University of Manchester Institute of Science and Technology, UK.

Wartime research on nitrogen mustard

SIR,—Thirty seven years ago the late Major J. M. Moore of the USA and I carried out classified experiments on the influence of nitrogen mustard — then a secret compound — on the bone marrow stem cells. Dameshek[1], Gilman[2] and Harrison[3] have commented on work prior to 1945 as being classified but important in the evolution of the treatment of leukaemia and cancer. Colleagues in Melbourne have suggested that for historical reasons we should have our work carried out in 1942 de-classified and published.

During the first world war mustard gas exposure in man was found to be associated with leukopaenia. This was believed to be due to superadded infection; it was not recognised that it was due to a chemical effect on the bone marrow.

In 1942 we tested the effect of nitrogen mustard on the bone marrow. We selected guinea pigs and compared the cellular distribution in bone marrow in a series of control animals against that of a series of similar animals exposed to the vapour of nitrogen mustard. Red marrow from the upper end of the tibia was examined. We found both the cells of the myeloblast series and the lymphoblast series were highly significantly reduced in numbers. This information was supplied to both the Ministry of Supply, London and also to Washington at that time. It is interesting to note that at that time much doubt was expressed that lymphocytes actually developed in bone marrow. This work was done in my laboratory at the University of Melbourne.

The Australian Defence Research Laboratory recently told me that there was no difficulty in obtaining security clearance for this work which was now common knowledge — but they were not able to find the documents recording the research of the "Gorrill" chemical warfare research team.

Our experiments on chemical warfare agents were essential to the war effort both owing to the capability of the Japanese in chemical warfare and the world ignorance of the precise effect of these agents under tropical conditions as applied to New Guinea. Unfortunately some years after the war, a directive was made that all documents relating to this work by the "Gorrill team" — later under the direction of another commanding officer — were to be destroyed. The senior official who destroyed them told one of us he though he might have been destroying significant scientific material. Under security wartime arrangements neither of us had copies of this document.

Yours faithfully,

E. R. TRETHEWIE

Obstructionists in environment clothing

SIR,—After its sincere start, "The end of the age of Aquarius?" (20 September, page 168) has been brought about in part by the duplicity of some so-called "environmentalists", who are, in fact, merely obstructionists. The writer personally investigated an attempt by such a group to include in the Organic Act, governing the US Bureau of Land Management, the setting aside of several square miles of rich coal lands in southern Utah as a sanctuary for the side-blotched uta, *Uta stansburyensis*. This small, brown lizard, with its subspecies, is common in suitable habitat over most of the Desert Southwest, from western Colorado to eastern California and is by no means in danger of extinction. Only the alertness of a US Senator from Nevada thwarted the move.

Even the discovery of the snail darter as an endangered species appears to have been based on an effort to block the construction of the Tellico dam, and not *vice versa*. Thus do the over-zealous and ulterior motivated subvert worthy endeavour, with the result that the efforts of the reasonable and sincere are eventually largely nullified.

Yours faithfully,

S. RALPH AUSTIN

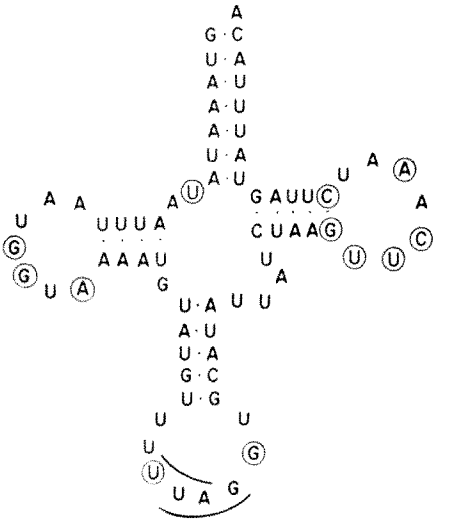
Mitochondria spring surprises



from B. D. Hall

THE concept of a totally universal genetic code was based intitially on studies of *E. coli*, tobacco mosaic virus, and human haemoglobin. The extrapolation of this conclusion from three genetic systems to all organisms was justified by the theoretical premise that any mutation which changed the ancestral code would cause so many different deleterious effects that it would have been selected against. Impressive though this argument may be, eukaryotic mitochondria have not heeded it. DNA-protein sequence comparisons for mitochondrial genes have revealed three variant codon assignments, at least one of which (UGA coding for tryptophan rather than acting as a termination codon) is used both in human and in yeast mitochondria.

The mitochondrial genome codes for a small number of proteins of the respiratory chain (eight in yeast) and contains genes for the tRNA and rRNA molecules of the mitochondrial translation system (Borst & Grivell *Cell* **15**, 705; 1978). Thus, as regards specification of the set of codons and anti-codons used, mitochondrial decoding of genetic information is autonomous and independent from that performed by the cytoplasmic system.

An extraordinary skewing of the mitochondrial codon usage pattern in favour of codons ending in A and U and away from those ending in G and C was evident from the first complete mitochondrial gene sequence determined, that for yeast ATPase subunit 9 (Hensgens *et al. Proc. natn. Acad. Sci. U.S.A.* **76**, 1663; 1979). For other yeast mitochondrial genes this same pattern holds, while for the single mammalian mitochondrial gene sequenced, only triplets ending in G are particularly infrequent.

The most surprising conclusion derived from the yeast subunit 9 gene sequence stems from an apparent conflict with the protein sequence (Sebald & Wachter, *29th Mosbacher Colloquium on Energy Conservation in Biological Membranes*, page 228; 1978). At position 46 the protein contains threonine, whereas the DNA sequence indicates a CUA codon (Hensgens *et al. op. cit;* Macino & Tzagoloff *Proc. natn. Acad. Sci. U.S.A.* **76**, 131; 1979), which normally codes for leucine. Follow-up sequencing studies established that the apparent discrepancy was due neither to a sequencing error nor to a genetic polymorphism. A structural basis for assignment of the CUA codon to threonine can be deduced from the sequence of an unusual yeast mitochondrial tRNA gene. Li and Tzagoloff have found (*Cell* **18**, 47; 1979) that a yeast mitochondrial DNA fragment which hybridises to $tRNA^{Thr}_{mt}$ contains a single tRNA gene sequence, that shown below

(From Li & Tzagoloff *Cell* **18**, 57; 1979)

This sequence differs from all previously-analysed tRNA sequences by having eight rather than seven nucleotides in the anticodon loop. Within this loop, the two nucleotide triplets nearest the centre are complementary to the nonsense codon UAA (overlined sequenced) and to CUA (underlined sequence). The mitochondrial tRNA transcribed from this gene may therefore be capable of accepting threonine and inserting it opposite the CUA codon triplet in ATPase subunit 9 mRNA and perhaps also at other CUA codons in mitochondrial mRNAs.

The second exceptional feature of the mitochondrial genetic code was discovered by similar protein — DNA sequence comparisons for cytochrome oxidase subunit II (COII), one of the three subunits of this enzyme which are made in mitochondria. The amino acid sequence of the COII protein has been determined for beef heart cytochrome oxidase (Steffens & Buse *Hoppe-Seyler's Z. Physiol. Chem.* **360**, 613; 1979), whereas the DNA sequences coding for COII have been identified in human and in yeast mitochondrial DNA. Barrell, Bankier and Drouin (this issue of *Nature*, page 189) have identified a sequence in human mitochondrial DNA which is colinear, identical in length and more than 70% homologous to the predicted COII coding sequence. Within this sequence there are three UGA codons in the translated reading frame. If we assume that the gene which has been sequenced does indeed code for human COII, it follows that there must be efficient read-through of UGA codons by the mitochondrial translation apparatus. This read-through is likely to be mediated by $tRNA^{Trp}_{mt}$ because each TGA in the human COII gene corresponds to tryptophan in bovine COII.

These strange goings-on in human cytochrome oxidase are not unique to our species. T. Fox of Basel University (*Proc. natn. Acad. Sci. U.S.A.*, in the press) has obtained very similar DNA sequence results for the yeast *oxi*1 locus, a mitochondrial gene which codes for yeast cytochrome oxidase subunit 2. The amino acid sequence of yeast COII decoded from the *oxi*1 DNA sequence, is 38% homologous to that of the bovine COII protein. This yeast gene, like its human counterpart, can only be translated to make COII protein if UGA codons are read as sense. Out of five TGA triplets in *oxi*1, four occur at positions where the bovine protein contains tryptophan. Similar conclusions were reached in an earlier publication which reported a partial DNA sequence for *oxi*1 (Macino *et al. Proc. natn. Acad. Sci. U.S.A.* **76**, 3784; 1979). These authors raised the possibility that UGA also is read as a sense codon in two other yeast mitochondrial genes, *oli*2 and *box*4.

As a third possible variation, Barrell *et al.* (*op. cit.*) note that in mitochondria AUA may code for methionine, rather

B. D. Hall is a Professor in the Department of Genetics, University of Washington, Seattle.

©1979 Macmillan Journals Ltd

than isoleucine. From an alignment of the bovine COII amino acid sequence with the sequence of codons in the human COII gene, they observed that methionines occur opposite ATG at two and opposite ATA at five positions. Provided there was no large scale evolutionary interconversion of isoleucine and methionine codons it would appear that AUA codes for methionine in human mitochondria. There is not yet enough protein sequence data to determine whether AUA also codes for methionine in yeast mitochondria.

The structural grounds for the AUA to Met and UGA to Trp codon assignments are presumed by Barrell *et al.* to be nucleotide bases present at the wobble positions in the anticodons in $tRNA^{Met}_{mt}$ and $tRNA^{Trp}_{mt}$. The presence of U or modified U at the 5′ end of the anticodon in each case might allow translation of AUA and UGA by A-U base pairing and of AUG and UGG by wobble base pairing (Crick, *J. molec. Biol.* **19**, 546; 1966). Recent sequencing work by Sanger and Coulson (cited by Barrell *et al.*) has established that the anticodon of human $tRNA^{Trp}_{mt}$ has a sequence consistent with these postulates.

These variations of the mitochondrial genetic code from that which directs translation in *E. coli* illustrate that, once a genetic code came into existence, it was not immutably fixed in all its details. Will still more exotic variations in the code be found in other organisms? For the answer, consult the dictionary in your favourite dinoflagellate, protozoan or archaebacterium. □

Antimatter from space

from P.C.W. Davies

THE origin of matter is one of the great unsolved problems of science: the visible Universe contains about 10^{50} tons of material. Where did it come from? At one time it was supposed that all this cosmic stuff — from which the galaxies, the stars and our own bodies are made — always existed. Modern cosmologists, however, believe that the Universe is not of unlimited age, but came into existence about 15 billion years ago in the hot, dense, explosive eruption, popularly called the big bang.

If this primaeval explosion marked the creation of all the cosmic matter, physicists would like to understand the details: what precisely happened in the first microsecond of existence? Since the early 1930s it has been known that matter can be created from energy in the form of subatomic particles, so modern cosmology provides a natural mechanism for the origin of matter: it was created from the explosive energy associated with the primaeval violence. Paul Dirac gave a very heuristic explanation of how this happens. The equation that describes a particle such as an electron possesses two sets of solutions: one describing 'ordinary' electrons and the other mysterious states in which electrons have negative mass-energy. As all systems tend naturally to seek out their lowest energy, nothing apparently prevents ordinary electrons from descending into these enigmatic negative energy states. As the energies can be limitlessly negative, there is a sort of bottomless pit into which all matter can disappear amid a shower of energy.

To preclude this apocalypse, Dirac proposed that the pit is blocked with an infinity of invisible electrons. If one of these invisible negative energy electrons is given enough energy it will be promoted to a real, observable, positive energy electron. Thus, a new electron will suddenly materialise in space. Furthermore, the 'hole' left behind represents the absence of an invisible negative energy electron, which Dirac reasoned is equivalent to the presence of a visible positive energy anti-electron, or positron as it is now called. The positron is a sort of mirror image to the electron; like the latter, but with all its physical attributes (for example, charge, spin, magnetic field) reversed.

Positrons were discovered among cosmic ray debris in 1932, and since then, antiprotons, antineutrons and a host of other antiparticles have been identified. Until recently it was supposed that the creation of matter must always be accompanied by an equal quantity of antimatter of the corresponding type. This inevitably implies that for every atom of ordinary matter that we see, somewhere in the Universe lurks its opposite number. Because any contact between matter and antimatter results in the matter falling back into the 'holes' and disappearing from the Universe, it must be supposed that somehow the matter and antimatter have got themselves well separated. It is fashionable to suggest that there are whole galaxies made of antistars and antiplanets and, one may conjecture, antipeople. An antigalaxy would look, on the face of it, indistinguishable from an ordinary galaxy.

When matter and antimatter annihilate each other their mass gets converted back into energy in the form of gamma rays, so by measuring the flux of gamma rays from space, limits may be placed on the amount of mixing that occurs between the two species of material. This seems to imply that almost complete separation has occurred, even on the scale of galactic clusters. Presumably they were put asunder in the earliest epochs of the big bang but just how this could have happened is still not completely clear.

In the past few years an exciting alternative picture has emerged. Ambitious new theories that seek to unify three of nature's four forces into a single mathematical description have predicted that perhaps matter can be created without an exactly compensatory quantity of antimatter. If this is so, it opens up the possibility of a lopsided Universe in which most of the antimatter has been annihilated, leaving a small residue of unbalanced matter that constitutes all the observed Universe.

To test which of these theories is closest to the truth, physicists can search for antimatter in space. Although the nearest antigalaxy may be millions of light years away, perhaps high energy subatomic antiparticles can stream across the gap and pepper the Earth. Cosmic ray showers have long been known to contain some antimatter (that is how the positron and antiproton were first discovered), but it has not hitherto been known whether these are merely by-products of high energy collisions between ordinary particles among the cosmic rays and the Earth's upper atmosphere. Now an experiment has been performed by a group of physicists from Texas and New Mexico to search for antiprotons among the primary rays (*Phys. Rev. Lett.* **43**, 1199; 1979). From a high altitude balloon flight last 21 June, the group detected 46 such particles, of which only about 18 are attributable to reactions with the atmosphere.

The ratio of antiprotons to protons coming from space works out at 5×10^{-4} in the energy range explored, which accords well with theoretical estimates based on the assumption that no external flux of antiprotons is bathing the Galaxy. They can all be accounted for as by-products of collisions between ordinary cosmic rays and the tenuous interstellar medium in deep space.

This experiment not only provides important information for understanding the origin and behaviour of cosmic rays in the Galaxy, but it tightens up further the evidence against a matter-antimatter symmetrical Universe. If matter really can be created and annihilated alone, it will open up whole new chapters in both cosmology and subatomic physics. □

100 years ago

In his last report from Saigon, Mr. Consul Tremlett alludes to his having been ordered by the Foreign Office to procure and send home a quantity of the bark known as *hwang-nao*, which during the past four or five years has been exported from Tongking to Trinidad, and there seems to have proved efficacious in cases of leprosy. The tree from which it is obtained is hardly known except to the missionaries, and is only found in the mountain forests of the north of Annam.

The road to unification

Sheldon Glashow, Abdus Salam and Steven Weinberg have won the 1979 Nobel Prize for physics for their great contributions to a unified theory of two of the fundamental forces of nature — the weak and electromagnetic interactions. But the theory took a long time to develop, and in that time many physicists other than those who were awarded the final accolade also made important contributions to it. On the next page Robert Walgate outlines the background of the theory and Norman Dombey traces here, for the initiated, the history of the Glashow-Salam-Weinberg model.

THE award of the Nobel prize in physics last week to Gashow, Salam and Weinberg can be seen as marking the end of the second phase of post-war theoretical particle physics. The first phase, which lasted until the mid-1950s was concerned with the development of quantum electrodynamics (QED) and is associated with the names of Tomonaga, Schwinger, Feynman and Dyson. The second phase begins with the discovery of 1957 of the non-conservation of parity in weak interactions — the interaction responsible for the neutron beta decay $n \rightarrow pe^-\bar{\nu}$ and muon decay $\mu^- \rightarrow \nu e^-\bar{\nu}$ — following its prediction by Lee and Yang[1].

After this, there was rapid progress in the understanding of weak interactions. Fermi[2] had written down a contact coupling of the four fermions involved in beta-decay in 1933 and for over 20 years it was the task of experimental nuclear physicists to work out the details of that coupling. The parity experiments then fixed the Fermi coupling as a current-current coupling of the neutron-proton or muon-neutrino current to the electron-neutrino current. (Current here has the technical meaning of behaving like a vector plus axial vector under Lorentz transformations.) Furthermore, the experiments showed that the strength of the vector part of the Fermi coupling G_v for beta-decay was almost precisely the same as G_μ for muon-decay.

A possible explanation for this was given independently by Gershtein and Zeldovich[4] and Feynman and Gell-Mann[3]. If the vector current of weak interactions were conserved, irrespective of whether it involves the strongly-interacting hadrons (nucleons, pions and so on) or only involves the leptons $\mu^\pm$, $e^\pm$, ν which have no strong interactions, then as in electrodynamics there is an associated conservation law. So in place of charge conservation, which leads to the equality of the electric charge of the proton and e^+, there is the weak 'charge' equality $G_\mu = G_v$.

Once this was accepted as a serious possibility, there was a clear analogy between the electromagnetic and weak interactions as both involved a conserved current and both were universal in that they involved leptons and hadrons with equal strength. There are of course many important differences: the characteristic strength of weak interactions is given by G_V where $G_V m_p^2 \approx 10^{-5}$ (m_p is the proton mass) whereas the equivalent strength of electromagnetic interactions is given by the fine structure constant $\alpha \approx 10^{-2}$; electromagnetic interactions conserve parity whereas weak interactions violate it maximally; electromagnetic interactions are long range whereas weak interactions act at a point; and so on. Using the analogy, Schwinger[5] in 1957 wrote down a unified weak-electromagnetic interaction based on the Yang-Mills[6] generalisation of QED. This involved a triplet (γ^+, γ°, γ^-) of charged photons: the theory conserved both charge and isotopic spin and thus provided a dynamical basis both for isotopic spin conservation and for the connection between charge and isotopic spin. Unfortunately, no zero mass charged photons have ever been seen.

Nevertheless, Yang-Mills theory does lead to a conserved vector current with charged components and that is precisely what is required for weak interactions. Schwinger had to assume that there was some mechanism by which the charged photons $\gamma\pm$ acquired a very heavy mass so as to simulate the pointlike character of the weak interaction: these were to become known as the intermediate vector bosons $W^\pm$ of the weak interaction. If this mass M_W satisfied $G_V M_W^2 \sim \alpha$, that is $M_W \sim 30$ GeV, then the resultant weak-electromagnetic interaction was unified in the sense that now α represented the coupling strength of both interactions. From this viewpoint, the reason that weak interactions were so weak was simply because the $W^\pm$ were so heavy that they were unlikely to be exchanged at the energies characteristic of nuclear physics. The properties of this theory were further developed by Schwinger's student Glashow[7] and Salam and Ward[8] during 1958.

Not many physicists took these early papers seriously as the parity-violating aspects of the charged weak current were completely unexplained and difficult to reconcile with the parity-conserving electromagnetic current. The first paper which made real progress was published by Glashow[9] in 1961 and provides the foundation of the present theory. Glashow showed that the parity properties of the electromagnetic and weak currents were possible to reconcile in terms of the known leptons provided that a triplet ($W^+W^\circ W^-$) of vector bosons coupled to the left-handed leptons while a fourth vector boson B° coupled to both left and right-handed leptons. Then quantum mixing between B° and W° gave rise to the physical states — the photon γ and a predicted neutral vector boson Z°. In this way it was possible to arrange that the photon coupled equally to left and right handed leptons thus conserving parity whereas Z° coupled unequally. So in this SU(2) × U(1) theory (the technical name of the underlying group), there was a new neutral weak current coupling to Z° which violated parity in a predictable non-maximal way. Glashow's work was followed in 1964 by an independent derivation of essentially the same result by Salam and Ward[10], who surprisingly were unaware of Glashow's work. The main difference between the two approaches is that Glashow has two left-handed doublets (ν_e, e^-), ($\nu_\mu\mu^-$) to describe the leptons whereas Salam and Ward preferred the group SU(3) and took the basic lepton triplet (μ^+, ν, e^-) with a 4-component neutrino instead of two 2-component neutrinos ν_e, ν_μ. Salam and Ward's choice allows certain possibilities absent for Glashow such as a neutrino magnetic moment and *vice versa*, but there is no necessary difference between the theories.

These early papers give most of the results of the present theory when applied to leptons. Nevertheless, the theories were not renormalisable: unlike in QED it was not possible to calculate higher order effects in the coupling constant α. The problem of calculating with massive vector bosons (that is spin -1 particles) had been known for many years. Such particles can have their polarisation vector either perpendicular (transverse) or parallel (longitudinal) to their direction of motion. A zero mass, spin -1 particle can by Lorentz invariance only have transverse modes but a massive vector boson must have the longitudinal mode too. The problem arises because the longitudinal polarisation vector has a component proportional to the momentum vector k_λ; hence the probability of emitting (or absorbing) the particles in their longitudinal mode will increase both with particle momentum/energy and with

the number of particles emitted. This is not possible in a sensible renormalisable theory which should give finite results at all energies and for any number of particles. In renormalisable theories all processes to any order in the coupling constant are calculable in principle.

Salam [11] in particular emphasised the importance of the renormalisability criterion and thought that it should follow as in QED from a principle of gauge invariance. In QED this is the statement that the components of the electromagnetic field vector A_λ in the direction of the photon momentum k_λ are redundant. It follows just as in classical electrodynamics that the photon (or electromagnetic wave) can only possess transverse modes, thereby removing the difficulty inherent in longitudinal modes. However, for QED to be gauge invariant the photon must have zero mass. Yang-Mills theory involves a more complicated gauge invariance where the 'photons' must also have zero mass.

The problem of inducing a vector boson mass without destroying the gauge invariance of the theory was actually solved in 1964 in some seemingly obscure work based on the theory of superconductivity. In superconductivity the ground state of the system is not invariant under the full symmetry of the interaction describing the system (a simpler example is ferromagnetism where the direction of the ferromagnet in its ground state clearly breaks the rotational symmetry of the underlying spin-spin interaction); an energy gap thus appears between the ground state and the lowest symmetric state. Nambu and Jona-Lasinio[12] showed that this process of spontaneous symmetry breaking (SSB) can be considered as the generation of mass for a fermion initially with zero mass but with a pairing interaction as in superconductivity. The energy gap behaves like a mass.

Brout and Englert[13] and Higgs[14] then showed that if one starts with a gauge theory involving a zero mass vector boson interacting with scalar fields, then SSB will generate a mass for the vector boson without destroying the gauge invariance of the underlying interaction. So it is possible that the good (that is, renormalisable) properties of the underlying theory are retained. In this case at least one scalar particle must also exist as a result of SSB.

It is surprising in retrospect that it took physicists three years to incorporate the ideas of SSB into unified weak-electromagnetic theory. In 1967 Weinberg[15] applied these ideas to Glashow's $SU(2) \times U(1)$ theory thereby predicting the mass relation $M_W = M_Z \cos\theta$ where θ is Glashow's mixing angle so giving the strength G' of leptonic neutral currents as $G' = \frac{1}{2}G_\mu$. Furthermore, the mass M_W is $37/(\sin\theta)$GeV or about 78 GeV with the present value for $\sin\theta$. Salam at about the same time was applying the ideas of SSB to his own and Ward's version of the theory. His results[16] are in agreement with those of Weinberg but his more general approach did not allow him to derive explicit mass relations for M_W and M_Z.

The rest is history. On the theoretical side, Glashow, Illiopoulos and Maiani[17] in 1970 introduced the concept of charm (*Nature* **262**, 537; 1976) thereby allowing the unified theory to be applied to hadrons and not only to leptons; the following year 't Hooft[18] showed in a *tour de force* that the Weinberg model was renormalisable. Experimentally, weak neutral currents were discovered in the remarkable experiment[20] at SLAC last year (*Nature* **274**, 11; 1978), when it was shown that left-handed electrons scatter off deuterons more than right-handed electrons.

In conclusion it is only fair to give credit to those whose work was inextricably linked with the development of the theory, which as is clear was very much a

What the theory is about

EINSTEIN spent the latter half of his life struggling to find a unified theory of the gravitational force and electromagnetism; he failed because he could not transfer the geometrical ideas of the general theory of relativity (his space-time theory — still the current theory — of gravitation) to the electromagnetic field. However he twisted and turned his electromagnetic 'vectors' and 'tensors' electromagnetism remained stubbornly non-geometrical: the electric and magnetic forces were something you simply had to add to space-time, like actors on a stage.

But now Glashow, Salam, and Weinberg, and the physicists who worked before and with them (see accompanying article) have turned the tables on Einstein by unifying electromagnetism with something else — the weak interaction, which if is responsible for the 'beta decay' of radioactive nuclei and for the transformation of protons into neutrons (and hence hydrogen into helium) that allows the Sun to burn. Both electromagnetism and the weak force are described in the theory as fields of force laid upon space-time; but they are now conceived as aspects of the same field of force, seen in different circumstances, just as magnetism and lightning are different aspects of the electromagnetic field.

Electricity and magnetism, incidentally, were unified by the Scot James Clerk Maxwell towards the end of the 19th century, in a 'field theory' which is still very much at the root of modern theories of fields of force. Maxwell showed that there must be propagating waves of electromagnetic field, and that they would travel at the speed of light; Hertz demonstrated their existence.

Light is an electromagnetic wave radiated by moving electric charges. It follows that if the weak force is to be combined in a unified theory with electromagnetism, there must be 'weak' charges and a corresponding radiation. In particle language (corresponding to the invocation of quantum mechanics, and the 'quantisation' of the field) there are photons (for light) and what came to be known as 'intermediate vector bosons' for the weak radiation. The difference is that photons are massless, and can cause interactions at infinitely long range, whereas the IVBs are massive and cause short-range forces. Thus the weak field of protons and neutrons cannot be felt outside the atomic nucleus whereas their electric field extends outwards and captures electrons, thus creating atoms. Inside the nucleus, the weak field causes beta dacay.

So far so good, but we still only have parallel theories, not unified ones. The next step was highly technical, and took a long time to emerge, but has very interesting consequences. It proved that the weak and electromagnetic fields could be understood as aspects of the same field only if the 'uni-field' was being propagated though a physical medium, the Higgs medium spreading throughout space-time. The medium was rather like calcite, which splits light into two beams according to its polarisation; the Higgs medium splits the uni-field (which has massless, long-range particles) into a heavy part (the IVBs) and a massless remainder (light).

Back to the aether, do I hear? Not quite. The medium is supposed to be real and detectable, and it obeys all the constraints of special relativity. Since it is uniform throughout space-time it is not noticeable until it is altered locally in some way, which cannot be done except at very high particle energies; but at those energies it is possible to predict that 'Higgs particles' will be created, like splashes in the medium (they will correspond roughly to density waves like sound in air).

The theory also predicts the exact masses and charges of the IVBs (there will be three, positive, negative, and neutral); and although it has been well verified at low energies in experiments with electrons and neutrinos, the real test will come with the detection (or not!) of the IVBs and the Higgs particles. Meanwhile particle theorists are attempting to apply the techniques of Higgs media (or 'spontaneous symmetry breaking' as it is called) to a unification of the weak, electromagnetic, and strong forces — without, yet, it must be admitted, much success.

Once the experiments that test the Glashow-Salam-Weinberg model have been done we shall know whether we are on the right lines or whether we have to start along a completely new track.

Robert Walgate

collaborative effort, but whose names were not chosen at Stockholm: in particular Ward and 't Hooft. It is also necessary to add the note of caution that so far neither the vector bosons $W^{\pm}$ and Z^0 nor the scalar particle implied by SSB have been discovered (*Nature*, **279**, 675; 1979). If the mass of the Z^0 is indeed 90 GeV as predicted, then it will be discovered in the next two or three years at PETRA in an e^+e^- experiment and at CERN in a $\bar{p}p$ experiment. If not . . . □

Small-scale solar magnetic fields

from Lawrence E. Cram

OBSERVATIONAL studies of the solar atmosphere show that a large fraction of the magnetic flux penetrating the solar photosphere occurs in elements with field strengths in excess of 1 kG. The elements range in size from large sunspots with diameters exceeding 20 Mm, down to tiny flux tubes whose diameters are inferred to be smaller than 100 km. The occurrence of strong fields in discrete structures of this kind has important consequences for our ideas concerning the generation, evolution and decay of solar magnetic fields, the structuring of the solar photosphere, chromosphere and corona, and the origins of non-radiative heating and mass transfer in the solar atmosphere. The observed properties and theoretical consequences of highly structured, intense solar magnetic fields were discussed at a recent meeting held at Sacramento Peak Observatory (SPO).*

J. Harvey (Kitt Peak National Observatory), summarised the current observational picture of small scale magnetic fields. Magnetograph observations of the net flux in areas greater than about $(2 \text{ arc s})^2$ show that in the quiet Sun almost all flux is concentrated in 1-2 kG 'bundles,' which occupy only a small part of the observed area. The area occupied by the stong field increases with increasing height, as the field flares out. In the general neighbourhood of the area where the flux elements penetrate the photosphere, there is a perturbation in the photospheric brightness distribution (called filigree or facular elements) and in the absorption line spectrum (line gaps); however, there is not a one-to-one spatial correspondence between the magnetic and brightness structures. This implies that there is not a tight temporal correlation between the evolution of brightness structures, which change in a few minutes and magnetic structures, whose evolution has not yet been studied with adequate spatial resolution.

The correlation between magnetic and velocity fields in the flux bundles is a perplexing problem. Many observers have found that the material in the magnetic elements is flowing downwards with a velocity of the order of 1 km s^{-1}. In a careful study, Giovanelli and Slaughter (*Solar Phys.* **57**, 225; 1978) showed that there is a downdraft whose amplitude increases with depth, highlighting the following problem: if the conductivity of the solar atmosphere is as high as is universally assumed, the field lines should be frozen into the plasma. If this is the case, whence comes the large mass flux that is continually flowing down the magnetic elements? Avoiding the problem of the origin of the downdrafts, E. Parker (University of Chicago) showed how the magnetic elements could be cooled, and thereby maintained in concentrated form, by such flows.

During periods of good seeing, the extremely sensitive Kitt Peak magnetograph reveals small-scale bipolar structures almost everywhere on the solar surface. These are distinct from the small-scale intense flux tubes that occur predominantly in the photospheric network, and are called the inner network field (INF). The properties of the INF are not well known. As A. Title (Lockheed) reported, a magnetogram obtained at SPO with 0.5 arc s spatial resolution does not reveal an INF component with a rms field strength exceeding 50 G. The possible existence of a chaotic magnetic field with a strength of a few gauss, pervading the entire solar photosphere, has great theoretical implications, and the demanding observational problems of high sensitivity and superb spatial resolution will be attacked by observers in an effort to tie down the properties of the INF.

Parker stressed the vital importance of solar studies as the foundation for astrophysics. "If we don't understand the relatively well-observed MHD phenomenon of sunspots, how can we have confidence in speculations about MHD and plasma processes in such objects as quasars and galaxies?" he asked. Parker described the physical basis of several characteristic properties of small-scale intense magnetic flux tubes, and highlighted some of the basic theoretical problems posed by the existence of small-scale magnetic structures and sunspots. His recent sunspot model (*Astrophys. J.* **230**, 905; 1979) was discussed, but the general consensus among observers and theoreticians alike was that the formation, evolution and decay of sunspots are, in most respects, unsolved problems.

N. Weiss (University of Cambridge) discussed the connection between surface magnetic fields and the magneto-gas dynamics of the solar interior. He emphasised the importance of flux emergence in ephemeral active regions (EAR, closely related to X-ray bright points). When these are taken into account, the rate of flux emergence through the solar photosphere is essentially constant through the solar cycle (about 3×10^{22} Mx per day), and is sufficient to replace the surface flux every 10 days. This fact, together with the fundamental property of solar magnetic fields to appear always in the form of strong-field flux tubes, poses tremendous problems for the theory of the cyclic generation, transport and reversal of solar magnetic fields by dynamo action.

The most advanced existing dynamo models are based on mean-field electrodynamics, but the existence of intense, inhomogeneous solar surface fields strongly suggests that mean field theory is inappropriate. Weiss suggested that a more realistic picture of the solar interior would involve a constantly changing framework of magnetic structures with convective eddies lying between them. Any description of dynamo action in such an intermittent magneto-convective region would involve a 'flux-tube dynamo.' Weiss sketched a model of this kind, involving field generation in a zone of penetrative convection between the solar radiative core and convective envelope. Such a model has the advantage of providing a relatively ordered field by avoiding the inevitable 'tangling' by convection acting over a time scale of years, and it also removes one of the major problems of flux-rope theories, that magnetic buoyancy in the convection zone forces flux to the surface too rapidly.

It is interesting to note how the changing observational picture of solar magnetic fields has vindicated many of the objections to conventional theories made by J. Piddington (CSIRO: see *Astrophys. Space Sci.* **55**, 401; 1978). Piddington has been frequently criticised for not providing a 'rigorous mathematical treatment' to support his ideas, but as he pointed out, "no treatment is acceptable, let alone rigorous, unless it is based first on adequate observational data and second on sound physical interpretation." Probably our understanding of solar magnetic fields will improve with the melding of Piddington's picturesque models with the powerful mathematical methods being developed to study intermittent MHD turbulence.

In summarising a number of important observational problems that emerged from the meeting, C. Zwaan (Utrecht) emphasised the need to study in detail the physical processes occurring in single small flux tubes. Such studies require sensitive velocity and magnetic field measurements to be made over relatively long periods with excellent spatial resolution. The 1.25 m Shuttle Optical Telescope (SOT) designed by R. Dunn (SPO) will provide the technological leap required to answer problems concerning solar atmospheric structures on the 100 km scale. Other important problems may not need such new instrumentation, but rather the careful application of existing equipment. One fascinating question is "how does

*A summer symposium on Small-Scale Solar Magnetic Fields was held at Sacramento Peak Observatory on 16-21 July, 1979.

magnetic flux disappear from the solar photosphere?''

There is a growing body of evidence pointing to the widespread existence of stellar chromospheres, coronas, and winds, all of which seem to be variable and many of which may be related to 'magneto-gas-dynamic processes' in stellar atmospheres. A sobering conclusion of the meeting was that we must do much more work to understand the intricacies of solar magnetic fields, and it will be a long time before a satisfactory account of stellar and cosmic electrodynamics is available.

Rapid screening of carcinogens — end of the beginning?

from Philip D. Lawley

THE problem of the aetiology of cancer is now of no mere academic interest, but of considerable socioeconomic importance, in the face of increasing public scepticism regarding effective prevention or treatment.

Recent recognition of the importance of rapid screening for potential carcinogens (almost synonymous with testing for potential mutagens according to methods devised by B.N. Ames) followed from the hope that elimination of these chemicals from the environment would lead to a significant reduction in cancer incidence. However, this optimism seems to be drifting away, as, for example, estimates of the occuational component of cancer incidence first increased, from their generally accepted lowish level (1-5%), to a forecast of 23-38%, followed by a reaction against the higher figures.

This sense of scepticism is not confined to epidemiologists and cancer aetiologists. If informed current opinion is represented by such a respected literary figure as Susan Sontag (in her recent book, 'Illness as Metaphor'), then both historically predominant themes in cancer aetiology, the 'environmental-mutagenic-chemical' and the 'hormonal-developmental-immunological', are dismissed, and *the* cause of cancer is maintained as an unsolved mystery. (These themes can be traced back, for the latter school of thought, to observations on proneness to breast cancer of 'melancholic' as opposed to 'sanguine' women by Galen (2nd century AD), or of nuns (Ramazzini, 1700); or, for the environmental school, to those on chimney-sweeps' cancer by Pott (1771)).

The more recent 'somatic mutation' theory originated a mere hundred years ago, and found biochemical support from observations that the alkylating agent, mustard gas, later established as a carcinogen in man, reacted with nucleic acids *in vivo*, a finding subsequently extended to virtually all classes of chemical carcinogen.

The invaluable 'Ames test' (in reality a mini-battery of tests using bacteria as the test organisms) permits rapid bioassay of chemicals, or their reactive *in vitro* metabolites, for mutagenic activity. However, to validate this test against many known carcinogens (established through conventional animal tests), it has been necessary to strip the bacteria of their DNA repair capability, and to sensitise them further by introduction of a mutator plasmid. The *in vitro* metabolic activation system (from liver of rats) rarely, if ever, mimics exactly the metabolism of carcinogens *in vivo*, even in rat liver, itself rarely the target tissue.

Furthermore, a fundamental difference exists between the DNA repair capability of bacteria and that of mammalian cells, which has been recognised from the earliest comparative work. Mammalian cells can reproduce aparently quite normally, as judged by survival of colony-forming ability and lack of induced mutation, despite incomplete removal of chemically (or radiation) induced DNA damage. Whether this indicates more effective repair (the remaining damaged DNA being redundant), or whether it is a source of further potential mutations, perhaps remains debatable. Nevertheless, mammalian cells, and in particular normal human fibroblasts, are remarkably resistant to low doses of mutagens or carcinogens, by these criteria.

The overall picture to the biochemist is, therefore, that any quantitative correlation between rapid screening data and the risk of human cancer from exposure to the test chemical is likely to be tenuous, *a priori*. Against this background, and with the now prodigious interest in, and expenditure on (at least in the US), this area of research, it was indeed appropriate that a conference* should be called to undertake a rigorous examination of this relationship. In addition, the associated fledgling topics of possible rapid screening methods for teratogens and nephro and neurotoxic chemicals were discussed, in the light of experience with the parent 'Ames tests'.

The topics covered in this blockbuster of a conference ranged from 'Molecular Mechanisms of Carcinogenesis' to 'Risk Assessment Approaches for Establishment of Criteria and Standards', culminating in a round-table discussion on 'Development of Environmental Policies', this last dominated by the eloquence of a named US Presidential candidate, B. Commoner (Washington University, St Louis).

On molecular mechanisms, the emphasis is shifting to recognition that while the intiation stage (somatic mutation) may be necessary for carcinogenesis, it is not of itself sufficient. Subsequent stages (denoted by some as 'promotion', somewhat to the dismay of P. Shubik (University of Heidelberg, an originator of the concept) may be at least as important, and there was much talk of 'synergism', 'cocarcinogenesis', and 'late stage carcinogens'. M. Radman (Université Libre de Bruxelles) thought that X-radiation had more of the characteristics of a promoter than of an initiator, and that promotion involved chromosomal rearrangement, but other speakers stressed the involvement of the interaction of promoters with cell membranes. Shubik questioned the tendency of some to attribute reversibility to the process of promotion.

With regard to the fundamental and over-ridingly important question of relevance of rapid-screening to the assessment of human cancer risk, I cannot do justice here to the thorough discussion of the topic that was given. As a UK taxpayer one remains uncertain whether shame at one's country's lack of expenditure on toxicology, or admiration of the US research effort in this area, should be the predominant emotion.

M. Waters (EPA, Research Triangle Park) showed convincing evidence from tests at various levels, and from epidemiological studies, particularly for a range of pesticides, that 'tier tests' were not an acceptable vehicle for assessment of cancer risk, and that a 'battery' of tests, including conventional animal life-time carcinogenesis studies, was notably less fallible. He held out some hope for a test based on transformation of human cells in culture, but the notorious difficulties already encountered seem to be in line with the known relative lack of susceptibility of normal human cells to carcinogens.

This indication also emerged from the thorough comparative assessments (by R. E. Albert (New York University) and others) of the results of quantitative animal carcinogenesis tests and human epidemiological studies, using the conservative assumption of linear dose-response at the low doses of environmental chemicals to which man is exposed. Generally man emerged as, at most, rather less susceptible to environmental carcinogens than the animals used in the conventional tests. From the reasonable estimates of the levels of environmental exposure, it seemed unlikely that these could account for a substantial proportion of the aetiology of human cancer. The current trend was expressed as 'downgrading of environmental causality'.

Another controversial issue concerned

the implications of results from rapid screening for regulatory policy. Previously (see *Nature* **278**, 388; 1979), President Carter's advisers at the US Office of Science and Technology expressed the view that "it is necessary to start by distinguishing scientific from regulatory decisions" — "scientific data collection and analysis" was one matter, but "cost benefit analysis" definitely another.

This view did not seem to be shared by B. Commoner, who began his presentation of results, from Ames tests of human body fluids and foodstuffs, by stating his belief that this type of experimental work could, in certain cases, supersede epidemiological studies, and did have direct implications for regulatory policy.

On the lighter side, he included an entertaining account of his work showing that red onions contain mutagenic flavonoids, leaving white onions, in the absence of any known specific nutritive value of their congeners, as winners in the risk-benefit analysis.

Some asperity developed between Commoner and R. Morgan (University of Toronto), who expressed the anguish of at least some of his fellow epidemiologists, that "the Ames test has led to more hypotheses than could possibly be tested", but, perhaps in some compensation, has been of distinct benefit to the legal profession. In an elegant presentation, Morgan showed that, in agreement with epidemiological experience, increasing the sensitivity of a screening test (certainly a marked feature of the history of Ames' tests) necessarily decreases its specificity and hence its predictive value.

The 'book of the meeting' will be required reading for many administrators (or indeed any of the public seeking a comprehensive view of this important area of research) as well as cancer aetiologists and toxicologists in general. □

The fascination of echinoderms

from Norman Millott

ECHINODERMS do things differently, which is one good reason why they have attracted increasing numbers of biologists with widely differing specialisations. This appeared to advantage in a recent colloquium*. Communications were so many and varied that only a few of the many excellent ones can be mentioned here.

Palaeontologists — seemingly tireless in their devotion to the group — were in part concerned with rare fragments of Jurassic echinoids from Western Australia indicating a wide and rapid spread of cassiduloids. Others challenged existing ideas concerning the primitiveness of the cidaroid lantern, or urged the need for a critical revision of classical changes in Adriatic echinoids to deepening of the sea, changes in climate and sediment and accumulation of calcium carbonate. D.G. Stephenson (Keele University) advanced yet one more idea concerning the seemingly eternal mystery of the five-rayed symmetry, showing that it could have conferred advantages in passive suspension feeding and could have been independently evolved in various groups of echinoderms.

Taxonomy, ever restless, was represented in the findings concerning holothurians of a 28-year survey of the Chinese coast, yielding incidentally, two new species and a proposed new genus. Other communications argued for regarding *Holothuria stellata* as a genuine species and for transferring the genus *Ophiocomina* to the Ophiacanthidae.

Ideas concerning the affinities and phylogeny of echinoderms invariably command attention. H. and G. Termier (Université P. et M. Curie, Paris) envisaged the evolution of coelomates as involving an early separation of echinoderms from lophophorates and chordates, with development of 'architectural' diversity and adaptive radiation in the Cambrian. R.P.S. Jefferies (British Museum (Natural History)) also painted a broad canvas, adding more detail to his picture of chordate evolution, deriving these animals from his palaeozoic Calcichordates, which show echinoderm affinities, yet possess what he interprets as tell-tale characters of chordates.

Echinoderms have nothing if not spectacular coelomic systems, achieving much by hydrostatic pressure, circulation of coelomic fluid and wandering cells. J. Binyon (Royal Holloway College, University of London) reported experiments determining the level to which fluid pressure could be raised in starfish before structural damage occurs, while C.W. Walker (University of New Hampshire) supported by direct observation, the importance of flagellated collar cells in producing coelomic circulation. Some functions of the ubiquitous wandering cells, including their bactericidal action, were elegantly demonstrated by L.I. Messer and A.C. Wardlaw (University of Glasgow) and a very different relationship with bacteria in *Leptosynapta* was reported by J-P. Feral (Museum National d'Histoire Naturelle, Paris) who described their constant association with cuticular structures. Others demonstrated the ultrastructure and symbiotic associations of amoebocytes, their relation to lesions in the body wall and their importance in transporting gut enzymes. The importance of the enigmatic 'haemal' system in moving assimilated substances, accumulating lipids and eliminating effete phagocytes was also indicated.

The extraordinary plasticity of peritoneal cells which Farmanfarmaian and I showed in 1967, received striking confirmation from A. Van Der Plas and M. Jangoux (Rijksuniversiteit, Utrecht & Université Libre de Bruxelles) who described the migration of these cells into the epithelial lining of the pyloric caeca of *Asterias* to form lipid stores showing changes related to the reproductive cycle.

Concerning the nervous system, there were reports of an unusual mode of dual innervation in echinoid podial muscles, of the importance of the radial nerve and its own sector of the nerve ring in the arm regeneration of *Asterina* and (for a change!) an analysis of associative learning in *Marthasterias*.

Physiological flexibility was the keynote of communications concerning rock pool species and the remarkable tolerance of sudden and extensive salinity changes of *Ophiura albida* in Loch Etive.

Much was said about nutrition, including the partition of energy between respiration, excretion and growth in plutei, and in starfish, changes in diet and population structure which occur with depth were reported, as well as the existence of a 'waiting stage' between larval and growing phases when food is scarce. Differing feeding processes in echinoids were correlated with differing fine structure of their radiole spines, and it was indicated that the shallow water holothurians of Enewetok Atoll do not occupy the same habitat unless they have different feeding habits.

Population dynamics with undertones of pollution and economics were represented in separate accounts of the effects of sewage sludge dumping near the mouth of the Elbe, where brittle stars were involved in the ensuing instability of the benthos, and of the possibility of introducing threatened edible species into suitable sites. Impressive densities of echinoderms off the west coast of Ireland and their dominant role in benthic economy were emphasised by a group of workers from University College, Galway. These were the contributions of professional scientists, but D. Nichols (University of Exeter) rightly paid tribute to the important contributions to his survey of threatened *Echinus*, made by amateur and professional divers.

As befits a modern programme, biochemistry and cytochemistry were represented by reports concerning the importance of steroids and the occurrence of gut enzymes in various species as well as the different aspects of the action of 1-methyladenine on starfish oocytes in which a calcium-binding factor resembling calmodulin was reported. □

Emeritus Professor N. Millott is at the University Marine Biological Station, Millport, Scotland.

*A European Colloquium on Echinoderms, dedicated to L. Cuénot, was held at the Université Libre de Bruxelles on 3-8 September. It was organised by Dr. M. Jangoux, Laboratoire de Zoologie.

AUTUMN BOOKS

Prometheus of the atomic age

Otto R. Frisch

Scientists in Power. By S.R. Weart. Pp.343. (Harvard University Press: Cambridge, Massachusetts, and London, 1979.) $17.50; £11.35.

IT is widely known that Enrico Fermi and his team started the first controlled nuclear chain reaction on December 2, 1942, in Chicago. This book tells us how a Frenchman, Frédéric Joliot, rather than Fermi, might have become the Prometheus of the atomic age, but for the German occupation of France. Madame Curie had picked the promising youngster for her assistant in 1925; she soon saw that he was a "skyrocket". Two years later he married her daughter Irène, the chemist, and thus entered the scientific circle, in the highly stratified society of Paris. Some saw him as a gate-crasher; and he always felt happiest with workers or fishermen.

His research at first brought him some disappointments. In 1931 he published observations which led James Chadwick to the discovery of the neutron and to the Nobel Prize; the next year he narrowly missed the discovery of the positron. But then at last came success: early in 1934 he and his wife published their observation of "artificial radioactivity". That important discovery brought them jointly the 1935 Nobel prize for chemistry and secured for Joliot the first Chair for Nuclear Chemistry, at the Collège de France.

In January 1939 Otto Hahn and Fritz Strassmann published their famous paper which indicated the fission of uranium nuclei struck by neutrons; Irène Joliot-Curie, who had narrowly missed that discovery, "bitterly regretted that she and her husband had not worked together on the problem, for their combined brains might well have solved it". At this point, about a quarter through the book, begins the main story.

Within a few days, Joliot had seen the stupendous implications of that new phenomenon: the possibility of a nuclear chain reaction which could release energy on a large scale. Leo Szilard had been looking for such a reaction since 1934, and Joliot had said in a public lecture in 1935 that "compared with the neutron, the philosophers' stone of the alchemists was a childish fantasy; doubtless people would soon be able to change lead into gold, but this would be an insignificant by-product compared with the enormous quantity of energy that would be released". Now, he felt, it was up to him to create that chain reaction which would present almost unlimited energy to France and hence to the world.

Enrico Fermi in the 1930s

Photo: AIP Neils Bohr Library

First of all he had to make sure that the fission of uranium nuclei released neutrons, as expected. Hans von Halban, son of an Austrian-born professor, was in Paris and keen to join Joliot in tackling that tricky problem, having gained experience with neutrons in Copenhagen (jointly with the reviewer). He in turn recruited Joliot's "little typist", a huge Russian called Lew Kowarski who was determined to become a scientist and did secretarial work to get a foot in the door and to supplement his meagre income from design work in a factory of gas pipes. Trained as a chemical engineer (see my obituary notice of Kowarski in *Nature*) he brought a valuable new way of thinking into the team. Those were the three musketeers who soon agreed that in publishing their joint work they would always share the credit for all ideas, whoever had thought them up.

By the end of February they knew that a chain reaction was not impossible: uranium produced more fresh neutrons than it swallowed. But were there enough of them? Some would escape from the material or be absorbed by its impurities. The team had to know the average number of neutrons released when a single uranium nucleus suffered fission, and by the end of April they thought that number was about 3.5. Today we know that the number is nearer 2.5, but perhaps the error was to the good; it made a chain reaction look easy to achieve and thus encouraged the team to redouble their efforts.

From the beginning they had studied uranium salts dissolved in water, in a tank about 1 m in diameter, with a neutron source at the centre. The neutron distribution in the tank was measured by placing small foils of dysprosium at various distances from the source and, after a standard time, measuring their radio-activity with a Geiger counter; that gave information on the number and the average speed of the neutrons. The water prevented most neutrons from leaving the tank and thus escaping scrutiny; it also served as a 'moderator' which slowed down the neutrons and made them more effective in causing fission. Promising as the results were they came nowhere near a self-sustaining reaction; it was soon clear that much more uranium would be needed.

In May 1939 Joliot approached the Union Minière du Haut-Katanga, a Belgian copper-mining firm which, almost as a sideline, extracted radium from its uranium ore. They had plenty of surplus uranium, and Joliot got them to ship five tons of pure uranium oxide to his Laboratory for Nuclear Synthesis at Ivry (near Paris), with its huge hangar and heavy handling equipment. In July Halban began the tedious neturon density measure-ments on spherical metal containers filled with a black mud, a mixture of uranium oxide and water, up to three atoms of hydrogen to one of uranium; the oxide would not soak up more water. When War broke out in September they had tested

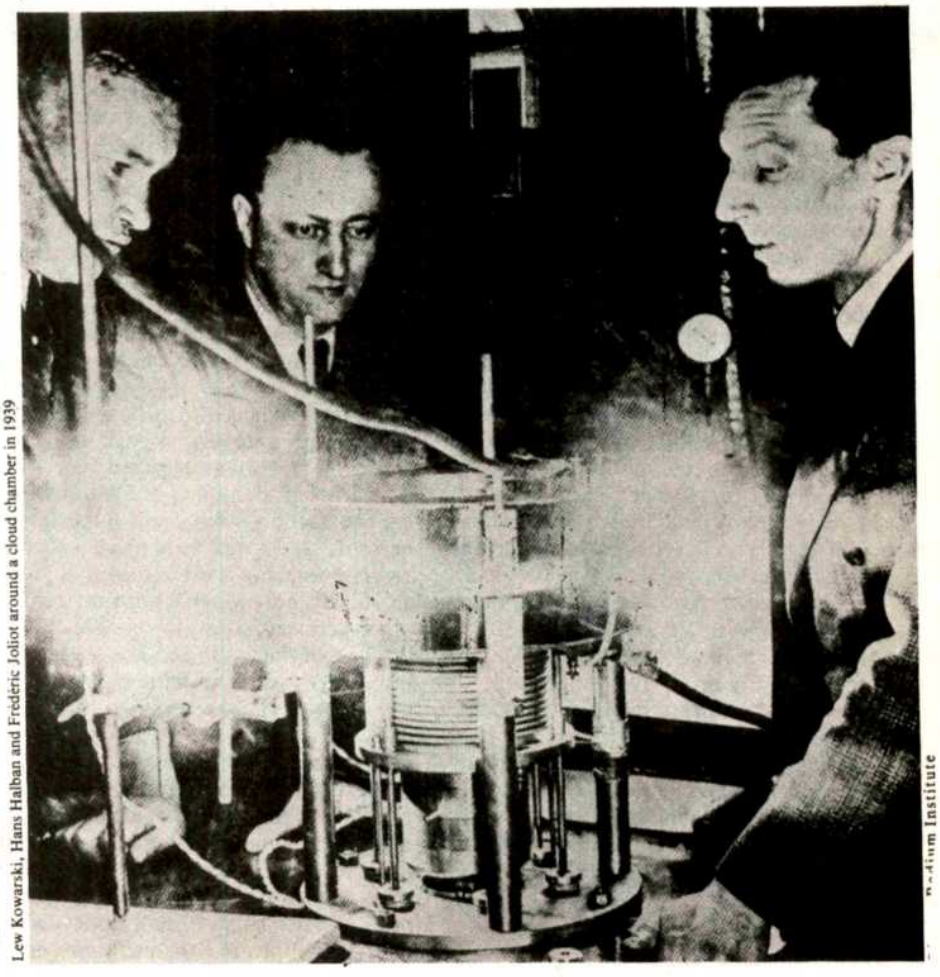
Frédéric Joliot, Hans Halban and Lew Kowarski with a geiger counter in 1939

Photo: Radium Institute

spheres up to half a metre in diameter and had clear evidence of a chain reaction that roughly doubled the number of neutrons that came from the source; but it was still far from self-sustaining. Water was not a good moderator; too many neutrons failed to cause fission because they were captured by its protons.

But what other moderator could one use? Carbon, as graphite, was available by the ton, but with its nuclei twelve times heavier than protons, neutrons needed many more collisions to become slow. Would they survive so many collisions without being captured? Much time was lost experimenting with piles of solid carbon dioxide ('dry ice') and industrial graphite; the results were promising but not conclusive. In the USA, similar work was done later and more carefully, convincing Fermi that graphite could be used; about the same time, a wrong result caused the Germans to abandon graphite as a moderator.



In the meantime Kowarski urged his team to consider heavy water: instead of protons it contains deuterons, only twice their mass, and it hardly absorbs neutrons. But it has to be extracted, at great cost, from ordinary water, of which it forms a minute fraction; in the USA, available only by the tumbler, its use was quickly dismissed. But in Europe the Norwegian firm Norsk Hydro had made almost 200 litres and were ready to increase production. In February, lieutenant Jacques Allier, a former employee of the French bank that controlled Norsk Hydro, went to Norway and persuaded them to hand over their whole stock, free of charge. The Germans were expected to interfere by force, and the entire operation reads like a spy thriller. Until the heavy water arrived in Paris in the middle of March, those two dubious foreigners, Halban and Kowarski, were interned for three weeks on two separate islands!

But in May the German army invaded France. After a brief attempt to set up a new laboratory in Clermont-Ferrand, Joliot decided that the team must split up; he would remain in France while Halban and Kowarski were to resume the work abroad. On June 17 they drove west in their cars, with their families, laboratory notes and the heavy water; in Bordeaux they embarked on a British collier which safely got them to London on June 22, just as France signed an armistice.

The British installed the team and gave them help at the Cavendish Laboratory, Cambridge. An aluminium sphere was constructed and filled with mixtures of uranium oxide and heavy water; it was made to rotate slowly to prevent the oxide settling to the bottom. After five months they had good evidence that a still larger sphere would give a self-sustaining reaction. But Fermi was still sceptical. Moreover, the USA were suspicious of Halban who stressed the French patents and got help from ICI (Imperial Chemical Industries); why help those probable post-war competitors? Negotiations dragged on for nearly three years.

To remove the work from this beleaguered island, a transfer to Canada was prepared; but when it at last took place late in 1942 — just as Fermi won the race for the chain reaction — some of the Cambridge physicists decided to stay with Kowarski, who had refused the inferior position Halban had offered him in Canada. Both teams had to live through another year of slow progress and low morale.

The Quebec Meeting of Churchill and Roosevelt finally enabled Canada to get information and heavy water from the USA. Replacing Halban, (Sir) John Cockcroft took charge of the Canadian team which was now joined by the Cambridge scientists. It took Kowarski less than a year to build a heavy-water reactor,

Lew Kowarski, Hans Halban and Frédéric Joliot around a cloud chamber in 1939

Radium Institute

which began to operate — the first outside the USA — a month after the War came to an end.

Joliot led a double life during the occupation. He kept his Paris laboratory going, but subtly sabotaged any research which Germany tried to conduct there; and he worked in the Resistance and came to admire the communists for their courage, idealism and competence. When France was liberated he was tireless in reviving fission research, amidst political strife and a ruined economy. Equipment was requisitioned or home-made; young people, attracted by the glamour of nuclear energy, were trained. Before Christmas 1948 the first reactor in France began to operate a heavy-water reactor, again built by Kowarski.

After that, the power of the scientists began to decline as the engineers, administrators and politicians took over. The declaration that France would never build nuclear weapons was gradually forgotten. Joliot's communist stance caused increasing problems, and after a rally in April 1950 when he declared that France would never make war on the Soviet Union he was removed from his post as head of the Commissariat à l'Energie Atomique. Large reactors were built, optimised for the production of plutonium, and the first French Bomb was exploded over the Sahara in 1960.

Joliot is clearly the hero of the book, a scientist who combined hard logic with lively imagination, and a persuasive personality with considerable skill as organiser. In his bid for nuclear power he was up against Fermi, probably the greatest all-round physicist of our time, as experimenter and theoretician alike, while France was short on theory. But Fermi was cautious and a foreigner in the USA while Joliot was full of fire and had the support of his country and his government. The author quotes Lord Blackett for saying "had the war not intervened, the world's first self-sustaining reaction would have been achieved in France".

This is a very well researched book, with its 12 pages of bibliography, 35 of footnotes, and a good index. But in spite of that scholarship the book is eminently readable and contains deft pen portraits of its many characters. It is written with a quiet dignity that yet does justice to the dramatic events with which it deals. Spencer Weart focusses on the French story but gives fair attention to efforts made elsewhere. Scientific explanations are kept fairly brief; much more space is given to the delicate interplay of social, economic and political forces; of great families and great schools; of scientists and administrators. Whichever way you look at it, this is a valuable and fascinating book. □

Otto R. Frisch was Professor Emeritus at Trinity College, Cambridge, UK. In Copenhagen he had contributed to the discovery of nuclear fission early in 1939. Professor Frisch died on 22 September, 1979.

Curiosity of a scientist

Hermann Bondi

Disturbing the Universe. By Freeman Dyson. Pp. 283. (Harper and Row: New York and London, 1979.) $12.95; £6.50.

OCCASIONALLY I feel unkind towards my many friends and colleagues in the education industry by pointing out that every small child makes a nuisance of itself by constantly asking "Why?", that society has developed a marvellous defence mechanism called education, and that this is so effective that it stops almost everyone from keeping on with this questioning. The few failures of this cure are, I claim, called scientists.

Curiosity must indeed be the mainspring of scientific endeavour. The constant nagging feeling of *wanting* to know something or other that is well hidden is indeed a powerful drive. To find out what a particular problem really is like and has as its solution, to worry the problem like a dog worries a bone, to gain insight by following to their end innumerable false turns, to see the whole confusing jumble eventually form a surprising and unexplored pattern, that is the real compulsive urge and joy of a scientist's labours.

To an extent that varies markedly between individuals there is associated with this an urge to communicate, an urge to teach, an urge to show to others the lovely pattern one has seen (whether one has found them or made them is a moot point) in one's own sandbox. Thus, research and teaching are naturally linked, but the link may take many different forms. To interest suitably qualified colleagues or research students in one's own researches is natural enough, but to watch a research student learn by making his own mistakes, perhaps messing up a lovely corner of one's sandbox is more of an acquired taste needing much self-discipline, but with its own rich satisfaction when one's pupil finally soars off under his own power. Undergraduate teaching is often seen as a chore, but only by those who have not got the urge to get across the beauty one sees in the structure of one's subject, the pleasure of conveying the personal pattern that one has seen (or made) in a well known part of the field.

Thus, there is substance to the notion of the normal academic career where one's researches (the value of which can be judged reasonably well) lead to posts in which teaching (the quality of which it is much harder for a university to assess) forms a major part of one's duties, along with continuation of one's research. However, justification for the curious habit of academic tenure (other than the mental comfort of the holder) can surely only be found if it enables the incumbent to follow daringly different unconventional and potentially fruitful pursuits on which he would otherwise not have embarked. Unhappily it is only a minute minority who so use their freedom. The vast majority of tenured academics, even of full professors who have nowhere further to rise, turn their academic positions or chairs, not so much into comfortable beds, as into narrow grooves of dried-up specialism often made most uncomfortable by making an 80 hour week out of administrative tasks that would take a competent bureaucrat half of an afternoon. Rare indeed is the person who really uses the freedom given by academic tenure to enrich the world and to enjoy himself by working hard and effectively at each in turn of the wide variety of pursuits he finds intriguing. Pre-eminently one such is Freeman Dyson, and his book is an exciting journey through the broad landscape of his experiences and thoughts.

Perhaps this is the point at which I should interpose the story of my period of friendship with the author which illustrates some of the bits he so oddly left out of the book. He does not mention his extraordinary brilliance at school at Winchester and as undergraduate at Trinity College, Cambridge, in the bumper class that had in it James Lighthill and Freeman Dyson, a record pair not equalled before or since. After the painful interlude of Bomber Command (fully described in the volume) he returned to Trinity as a young Fellow a few years my junior. An inveterate talker like myself (I recall his interrupting me at High Table dinner with "Not another word now. We are still on the soup while the other are finishing their desserts") he clearly had a most enjoyable year, but found that Cambridge, with its then rigid barrier between Physics and Mathematics was not a good place to learn and work in the lively field of theoretical quantum physics he wished to pursue. Hence his move to Cornell and Hans Bethe, where his book restarts. Why this odd omission of Cambridge?

He relates how he learned, travelled, and did brilliantly, none of which surprised me. But I was astonished and a little worried when he accepted a permanent position at the Institute of Advanced Studies in Princeton. That such an able and enterprising young man should take a post from which there was no escape upwards in academic life, a post that would hang round his neck for nearly 40 years, that would prevent him from teaching anyone but a few highly selected graduate students, that would isolate him in a closed esoteric community, all this saddened me greatly. How wrong I was to worry is so beautifully shown in his book. To him the Institute post was simply a springboard for pursuing

The Biology of the Lymphokines

edited by Stanley Cohen, Edgar Pick and Joost J. Oppenheim

December 1979/January 1980, 656pp., £18.50/$42.50 0.12.178250.6

The Biology of the Lymphokines is the first volume devoted entirely to the subject of lymphokine biology. The leading investigators in this burgeoning field contribute up-to-date reviews on major areas such as the cellular origin, biochemical characteristics, mechanism of action, biological relevance, pharmacology, and clinical application of lymphokines. A well-balanced view is provided of the multiple involvement of lymphokines in immunological as well as non-immunological events. The synthetic treatment of the subject makes this book essential for immunologists, cell biologists, biochemists, microbiologists, haematologists, pathologists, and medical researchers generally.

Sexual Selection and Reproductive Competition in Insects

edited by Murray S. Blum and Nancy A. Blum

September 1979, 476pp., £14.95/$23.00 0.12.108750.6

Contents include: D. Otte: Historical development of sexual selection theory. **G. Borgia:** Sexual selection and the evolution of mating systems. **R. Thornhill:** Male and female sexual selection and the evolution of mating strategies in insects. **G. A. Parker:** Sexual selection and sexual conflict. **W. D. Hamilton:** Wingless and fighting males in fig wasps and other insects. **D. K. McAlpine:** Agonistic behaviour in *Achias australis* (Diptera, Platystomatidae) and the significance of eyestalks. **W. G. Eberhard:** The function of horns in *Podischnus agenor* (Dynastinae) and other beetles. **D. Otte and K. Stayman:** Beetle horns: some patterns in functional morphology. **J. E. Lloyd:** Sexual selection in luminescent beetles. **W. Cade:** The evolution of alternative male reproductive strategies in field crickets.

Frontiers in Physicochemical Biology

Proceedings of an International Symposium held at the Institut de Biologie Physico-Chemique, Foundation Edmond de Rothschild, in May 1977

edited by Bernard Pullman

March 1979, 528pp., £29.25/$45.00 0.12.566960.7

The twenty-one papers assembled in this volume represent a unique, overall survey of the important developments in nucleic acids and protein interactions, genetic regulation, molecular biology of oxygen and haemoglobin, and the bioenergetics of organised systems from a biophysical and biochemical perspective. They have been written by the world's most eminent specialist in the field. The book is divided into four main parts: The physical chemistry of fundamental biomolecules; The physiochemical aspects of the mechanisms of genetic expression; Biochemistry of oxygen and haemoglobin; Study of organised systems.

Cell Biology and Immunology of Leukocyte Function

Proceedings of the Twelfth International Leukocyte Culture Conference held at the Ben Gurion University of the Negev, Beer Sheva, Israel, June 25-30, 1970.

edited by Michael R. Quastel

August 1979, 1002pp., £29.40/$45.00 0.12.569650.7

The book opens with a group of papers on the mechanism of lymphocyte activation, a subject of perennial interest, and the main theme running through all previous volumes of the series. Subsequent sections deal with lymphocyte differentiation, the genetic control and intracellular interactions involved in leukocyte function, parameters of the immune response under *in vitro* conditions, the interactions of viruses and lymphocytes, and the application of leukocyte culture to problems of clinical medicine. The final part of the book involves a new subject for this series, the study of radiation effects and leukocyte malignancy.

Marine Pollution

Functional Responses

edited by Winona B. Vernberg, Frederick P. Thurberg, Anthony Calabrese and F. John Vernberg.

September 1979, 464pp., £15.00/$23.00 0.12.718260.8

From the preface: The papers in this volume were presented at a symposium entitled "Pollution and Physiology of Marine Organisms" held at Hobcaw Barony, Georgetown, South Carolina in November 1977 . . . There has been a veritable explosion in interest in this subject in the past few years, and we are grateful to Carl Sindermann for his thought-provoking and incisive overview of our present level of knowledge as well as charting where our future needs lie. It is clear that we have long passed the point where death is the only criterion for determining whether a substance is harmful or not and the large number of papers on sublethal effects in this volume attest to this present trend in physiological pollution studies.

Ultrastructure of the Rust Fungi

Larry J. Littlefield and Michele C. Heath
October 1979, 296pp., £24.80/$38.00 0.12.452650.0

Contents: Morphology and ontogeny of sori and spores: Basidiospores. Pycnia and Pycniospores. The Dikaryotization Process. Aecia and Aeciospores. Uredia and Urediospores. Telia and Teliospores. Overview. **Infection of the susceptible host:** Directional Growth of Urediospore Germ Tubes. Induction of Appressoria. Development of Infection Structures. **Vegetative growth in the susceptible host:** Intercellular Hyphae. Intracellular Structures. **Nuclei:** Interphase Nuclei. Nuclear Division. **Incompatible plant-rust associations:** "Natural" Resistance. Resistance Elicited by Systemic Fungicides. **Parasites of rust fungi:** Fungi. Viruses.

Versatility of Proteins

Proceedings of an International Symposium on Proteins held on March 6-8 in Taipei.

edited by Choh Hao Li
March 1979, 408pp., £14.30/$22.00 0.12.447750.X

Contents include: K. A. Walsh et al: Strategies of amino acid sequence analysis. **T. Wieland:** Solution vs. solid-phase methods in peptide chemistry. **D. Yamashiro and J. Blake:** Improved procedures for the solid-phase synthesis and purification of peptides. **J. T. Yang and C.-S. C. Wu:** Surfactant-induced conformation of some oligopeptides, polypeptides, and proteins: helix- and β-forming potential of amino acid sequence in proteinaceous environment. **H. A. Scheraga:** An approximate model for protein folding: experimental and theoretical aspects. **E. H. Fischer et al:** Evolutionary aspects of the structure and regulation of phosphorylase kinase.

The Role of Insectivorous Birds in Forest Ecosystems

Proceedings of a symposium, The Role of Insectivorous Birds in Forest Ecosystems, held on July 13-14, 1978, in Nacogdoches, Texas, sponsored by the School of Forestry, Stephen F. Austin State University, and the USDA Forest Service, Southern Forest Experiment Station, Wildlife Habitat and Silviculture Laboratory.

edited by James G. Dickson, Richard N. Conner, Robert R. Fleet, Jerome A. Jackson and James C. Kroll.
October 1979, 400pp., £15.60/$24.00 0.12.215350.2

Contents include: Censusing Birds: L. J. Folse Jr.: Analysis of community census data: a multivariate approach. **W. M. Shields:** Avian census techniques: an analytical review. **Sampling Prey Populations: R. Coulson et al:** Sampling considerations for evaluating the effects of mortality agents on bark beetles. **J. A. Jackson:** Tree surfaces as foraging substrates for insectivorous birds. **Foraging Strategies: R. N. Conner:** Seasonal changes in woodpecker foraging methods: strategies for winter survival.

The Study of Prosimian Behavior

edited by G. A. Doyle and R. D. Martin
July 1979, 704pp., £32.15/$49.50 0.12.222150.8

This book gives perhaps the first comprehensive, state-of-the-field picture of research on prosimian behaviour. With the growth of research in this area, a book on the subject is now possible. The contributors to *The Study of Prosimian Behavior* report experimental laboratory studies, studies of normal behaviour in semi-natural settings, and studies in the natural habitat by means of such sophisticated instruments as infrared devices and radio-tracking equipment. Topics covered include: reproduction and maternal behaviour; learning and intelligence; diet; locomotion; ranging behaviour; vision and olfaction; classification; phylogeny.

Cell-Associated Water

A workshop — organised in connection with the First International Congress on Cell Biology, Boston, September, 1976.

edited by W. Drost-Hansen and James S. Clegg
July 1979, 450pp., £14.30/$22.00 0.12.222250.4

Contents include: J. E. Morel and M. P. Gingold: Does water play a role in the stability of the myofilament lattice and other filament arrays? **P. M. Wiggins:** Metabolic control of the properties of intracellular water as a universal driving force for active transport. **R. M. Hurtado and W. Drost-Hansen:** Ionic selectivities of vicinal water in the pores of a silica gel. **F. M. Etzler and W. Drost-Hansen:** A role for water in biological rate processes. **C. F. Hazlewood:** A view of the significance and understanding of the physical properties of cell-associated water.

Antibody Production in Man:

In Vitro Synthesis and Clinical Implications

Anthony S. Fauci and Rudy E. Ballieux

September 1979, 408pp., £11.80/$18.00 0.12.249950.6

From the preface: On March 15-18, 1978, the Catharijne Conference was held in Utrecht, Holland . . . The workshop was divided into four major sessions preceded by an introductory lecture by Dr. Max D. Cooper entitled "Consideration of Antibody Deficiency Diseases in Relation to Normal B Cell Development". The actual workshop sessions were concerned with mitogen induced B cell activation, antigen induced B cell activation, subpopulations of lymphocytes involved in the regulation of *in vitro* B cell function, and clinical implications in the study of *in vitro* B cell function.

Pine Barrens: Ecosystem and Landscape

edited by Richard T. T. Forman

November/December 1979, 624pp., £25.65/$39.50 0.12.236450.0

Contents include: People: P. O. Wacker: Human exploitation of the New Jersey Pine Barrens before 1900. **J. E. Applegate et al:** Plant and animal products of the Pine Barrens. **Geology and Soils: E. C. Rhodehamel:** Geology of the Pine Barrens of New Jersey. **Climate, Water and Aquatic Ecosystems: A. V. Havens:** Climate and microclimate of the New Jersey Pine Barrens. **E. C. Rhodehamel:** Hydrology of the New Jersey Pine Barrens. **Vegetation Patterns: C. J. Heusser:** Vegetational history of the Pine Barrens. **Plants: F. T. Ledig and S. Little:** Pitch pine *(Pinus rigida Mill):* ecology, physiology and genetics. **Animals and Animal Communities: L. J. Wolgast:** Mammals of the New Jersey Pine Barrens. **C. F. Leck:** Birds of the Pine Barrens. **R. Conant:** A zoogeographical review of the amphibians and reptiles of southern New Jersey with emphasis on the Pine Barrens. **R. W. Hastings:** Fish of the Pine Barrens. **H. P. Boyd and P. E. Marucci:** Arthropods of the Pine Barrens. **Conclusion.**

Chemical Compounds in the Atmosphere

T. E. Graedel

September 1979, 456pp., £19.15/$29.50 0.12.294480.1

A unique, practical encyclopedic reference work for atmospheric scientists, chemists, chemical engineers, and workers in the environmental sciences, this is the first comprehensive assemblage of information on atmospheric compounds. It provides data on the sources, ambient concentrations, reactions, products, and atmospheric lifetimes of more than 1600 compounds emitted into, or present in, the Earth's atmosphere. Information has been gathered and synthesized from over 800 sources in fields ranging from forestry to physics. Three different cross-reference tables make the material conveniently available to users with a variety of interests.

Viruses and Environment

Proceedings of the Third International Conference on Comparative Virology, held at Mont Gabriel, Quebec, Canada, in May 1977.

edited by Edouard Kurstak and Karl Maramorosch

July 1979, 696pp., £20.80/$32.00 0.12.429766.8

Viruses and Environment presents the current trends prevailing in virus research, and the deep implications and the role of viruses in biological and environmental studies. The scope and objectives of this work encompass the impact of viruses on the environment, the latest findings concerning persistent virus infections of man, vertebrates, invertebrates, and plants, as well as a discussion of the smallest disease agents, the viroids. Among the timely areas presented are the discussion of the precautions to be taken in the use of live viruses either as vaccines or biological control agents and in genetic engineering.

Physiology of Woody Plants

Paul J. Kramer and Theodore T. Kozlowski

September 1979, 832pp., £22.75/$35.00 0.12.425050.5

Both a basic text and a practical reference, this comprehensive, authoritative synthesis brings together the current state of knowledge on how woody plants grow. It describes in detail the physiological processes and structural features involved in growth as well as the internal, environmental, and cultural factors influencing growth. The book differs from most textbooks on plant physiology in that strong emphasis is placed on tree structure and on the interactions of trees and stands of trees with their environment. It is well documented with more than 2000 references from the world literature.

his foibles, and for one such as Dyson each foible is both what would be the adventure of a lifetime for others and a notable contribution to mankind's storehouse of knowledge and experience.

Two of his particular characteristics are to be totally fascinated by space, and to be deeply interested in nuclear power. He describes with such evident joy his cooperation with a brilliant group of people to design the 'inherently safe' Triga nuclear research reactor. In very little time the endeavour was most successful, and dozens of these reactors were sold. Not long afterwards Dyson was involved with the splendidly conceived Orion project which aimed to use nuclear power to make space travel cheap and fast. In the end, this endeavour was doomed through external developments. He describes his involvement with molecular biology more sketchily but the depth of his understanding is evident. Politics fascinated him, not the strident shouting of electioneering that is so liable to expand minor differences of judgment on non-central issues into great philosophical divisions, but the patient work of exploring how the most deeply held and widely differing convictions can be reconciled in modest and valuable programmes of action. His work in the Arms Control and Disarmament Agency and his efforts in the Princeton Citizen's Committee to advise on whether recombinant DNA researches should be permitted are all lovingly related in a most human and readable manner. Much earlier, in the Oppenheimer tragedy, he seems to have been only a spectator, naturally an immensely concerned spectator, but one with much understanding of how some actors came to what he regards as utterly wrong choices. This was his blooding in politics, and if it left him wounded, he was keen to point out the total absence of scars.

But perhaps the most thrilling part of the book deals with his deep speculations on mankind's future in space as he sees it. I happen to be more of a doubter in this field, but I too was carried along by the sweep and logic of his vision, by his imaginative application of knowledge, by his sheer enthusiasm. I tend to think that the solution of our problems on the Earth must be found on the Earth, but his comparison with older efforts of settling new lands is certainly intriguing and well argued, his view of the need for adventure is stimulating, and the whole section is not just very readable, but truly exciting and thought provoking.

I am less enthusiastic about the pieces of Dyson's personal history in the book. They certainly are well chosen fragments, but they are only fragments. One's personal life is a continuous chain of experiences and impressions, each section being properly intelligible only in the light of its predecessors. His episodes, though, make excellent reading matter. He is also curiously reticent about his scientific work since his appointment to the Institute.

Freeman Dyson

Photo: Camera Press

But to come back to the mainstream of his book, I was especially intrigued by his fascination with engineering, a fascination I, as another theoretical physicist, share with him, though he came to it earlier in life than I did. But where he and I differ is in our attitudes to bureaucracy. It is natural for a scientist to feel antipathetic to big organisations. The brilliant ideas, the outstanding contributions we most admire and indeed venerate, are necessarily the product of one person's mind, or very occasionally of two or three closely collaborating minds. Ten thousand mediocrities working for ten thousand years could not have duplicated Einstein's ideas or those of Charles Darwin. Exceptional quality of mind is needed in our fields and cannot be replaced by quantity. But great engineering projects like Apollo, or the Forth Bridge, or Concorde, are created, and can only be created, by vast impersonal organisations responding only slowly and gently to any

ELLIS HORWOOD

Publishers Chichester

CELL POPULATIONS

Editor: **E. Reid,** *Director, Wolfson Bioanalytical Centre, University of Surrey*

This desk guide to new and established methods of isolating cell populations from tissues or other heterogeneous biological sources surveys techniques for obtaining homogeneous samples of healthy cells from mammalian tissues, and from protozoan and other free-living cells. It also offers guidance on the choice of the most suitable methods. The range of techniques covered includes sedimentation, isopynic banding, elutriation, partition between two aqueous phases, and free-flow electrophoresis. It will serve as a research and laboratory reference book, or as a teaching aid, providing also adequate background knowledge for non-specialists. It is an authoritative coverage of the field by an international team of experts, first presented at a Subcellular Methodology Forum held at the University of Surrey in 1978. There is no such wide-ranging survey of its size known to be available.

Contributors include: W.S. Bont, N. Crawford, M.J. Crumpton, W.H. Evans, R.J. Hay, H.G. Heidrich, G. Johansson, D.L. Knook, H.A. Krebs, S.M. Lanham, J.P. Luzio, H. Pertoft, G. Raydt, I. Schulz, P.O. Seglen, and Th. J.C. van Berkel.

PLANT ORGANELLES

Editor: **E. Reid,** *Director, Wolfson Bioanalytical Centre, University of Surrey*

This comprehensive and critical survey of known methods of the isolation of organelles and membrane material from plant tissue also emphasizes the advances in the field.

The book first considers methods for isolating bioenergetic organelles, and then presents current views on vacuoles and microbodies. There is consideration of membranous components and nuclei, and of constituents such as glucan synthetases and phytochrome, with attention to lectins, auxin binding and glycosyl transferases. The critical collation of current thinking on markers for characterizing subcellular fractions concludes this outcome of a Subcellular Methodology Forum held at the University of Surrey in 1978.

change in direction, whether the command comes from a genius or from a mediocrity. They can be accelerated slightly be leaders of great drive, and lose momentum without leadership. But invariably they grind on remorselessly, very inefficiently, but necessarily successfully, for only mass murder could stop them in their tracks.

It needs a certain type of sophistication to derive job satisfaction from the awareness that, without one's sustained efforts over a year, the organisation would be moving in a slightly different direction, and would not have got quite so far. Such a form of sophistication Dyson does not have. To him only work in a small group is fun. This attitude separates him from much modern engineering and from much that is involved in the public service. He is thus a supporter of small bands of pioneers rather than of large project management teams. It is a great loss that our necessarily large bureaucracies are unable to attract such talent.

I am sure I have said enough to make it clear that I thoroughly enjoyed reading this book, that it gave me a lot to think about, and that I can recommend it heartily to all. □

A man who thinks otherwise

Eric Ashby

The Medusa and the Snail: More Notes of a Biology Watcher. By Lewis Thomas. Pp. 175. (Viking: New York, 1979.) $8.95. (A UK edition will be published after May next year by Allen Lane (London).)

IN far off days, when the academic profession was a revered élite, the Germans defined a professor as "a man who thinks otherwise". In these days, when knowledge is fragmented and the academic profession unionised, otherwise-thinking is rare, even among professors. Hence the significance of this little book of essays, for Lewis Thomas is a virtuoso in thinking otherwise.

At first glance the book seems to be lightweight, no more than a capricious assortment of fancies about ponds in Manhattan, cloning of human beings, committees, punctuation, disease, death, warts; all gently mischievous, witty, conversational in style, the work of a latter day Montaigne or Lamb. Those who have read Thomas' other essays (*The Lives of a Cell: Notes of a Biology Watcher;* Viking: New York; Garnstone: Petworth, UK; for review, see *Nature*, **258**, 24; 1975), know how misleading such a first glance would be. In common with another Lewis, Lewis Carroll, he has an extraordinary intellectual exuberance. I have not read any of his papers on pathology (Thomas is a distinguished pathologist) but I guess they are as unlike *The Medusa and the Snail* as Lewis Carroll's *Euclid and his Modern Rivals*, published just 100 years ago, is unlike *The Hunting of the Snark*.

Carroll wrote for children. Thomas writes for grown-ups who still retain a child's capacity for wonder. Apart from his mastery of prose, which makes me green with envy, he has a rare talent for picking up something familiar and suddenly, with a flash of imagination, giving it a fresh meaning. It's done deftly, like a conjuring trick. It's the technique of a poet. Edith Sitwell used it effectively; she described it once to me as a "leakage of thought" from one compartment of the mind to another. Thomas himself describes it: "finding the marks of remote similarity, points of distant relationship, tiny irregularities that indicate that this one is really the same as that one over there only more important". And in an essay on thinking about thinking he tries to describe the process. The human head, he writes, "is filled alive with molecules of thought called notions. . .flowing at random from place to place, bumping against each other. . .like the paths of Brownian movement". The mind is heated a little, the movement speeds up, there are more encounters, some of the notions dock and lock (notice the imagery of space-travel), aggregates are formed, they act like "purposeful organisms, hunting for new things to fit with. . .turning things over, catching at everything" — and a harmonious idea is generated, with the elegant geometry of a Brandenburg concerto. At that point Thomas' mind takes another leap: why not begin with music "and see what this can tell us about the sensation of thinking".

So far so good: the book is delightful entertainment. Is it more than that? I believe it is. It is a piece of intellectual autobiography. Its theme is the impact of Nature on Lewis Thomas. By what I believe is a valid extrapolation, it speaks for thousands of other less articulate biologists and naturalists; and this is why it is more than entertainment. Thomas visits the Tucson Zoo and watches beavers and otters at play in glass-walled pools. For a few minutes he sheds his professional reductionist shell and becomes, as he puts it, "transfixed. . .there was only one sensation in my head: pure elation mixed with amazement at such perfection". The beavers and otters had done something to him. "I learned nothing new about them. Only about me, and I suspect also about you, maybe about human beings at large: we are endowed with genes which code out our reaction to beavers and otters, *maybe* [my italics] *our reaction to each other as well*".

Speculation, bordering on the turbulent territory of sociobiology? Perhaps it is, but there is no dogmatic assertion in Thomas' reflections. He offers you a subjective experience, take it or leave it. I would be surprised if many biologists reject the *credo* which is the main motif in these essays. The *credo* rests on wonder at two principles Thomas finds all around him. One is uniqueness; the other is symbiosis. Here are a few examples of the impact they make on him.

To say that the DNA molecule is the greatest single achievement of Nature is a commonlace opening for an essay. But then Thomas goes on to wonder whether molecular biologists could have achieved this, if they had been flown from another planet to start life off on Earth. Suddenly comes the refreshing insight: "We would have made one fatal mistake: our molecule would have been perfect. Given enough time, we would have figured out how to do this, nucleotides, enzymes, and all, to make flawless, exact, copies, but it would never have occurred to us, thinking as we do, that the thing had to be able to make errors. The capacity to blunder slightly is the real marvel of DNA. Without this special attribute, we would still be anaerobic bacteria and there would be no music. . .it is no accident at all that mutations occur; the molecule of DNA was ordained from the beginning to make small mistakes".

This is the source of the uniqueness of living things, of the idea of selfhood. In the *Testament of Beauty* Robert Bridges came to a similar conclusion along a different path. Thomas takes the scientist's path. He cites the self-labels of beans — the glycoproteins which may negotiate the intimate concordat between bean and nitrogen-fixing bactera; he cites the capacity of fish and mice to tell each other apart as individuals by a sense of smell; and he concludes that nucleated cells detached from the parent organism seem to be the only living units without a "sense of privacy". It is no wonder he has deep reservations about cloning human beings. Of course, like any other professional biologist, he doesn't think it is likely to happen; but suppose it did: think what this would do to filial affection and paternal care; think of the terrifying prospect of raising from infancy and teaching language and discipline to a creature whose genetic constitution is exactly the same as your own. In any case, as Thomas explains, it couldn't happen because the selfhood of human beings depends not only on their genes but also on their environment, including their personal relations with other human beings, and it would be

Human Nutrition
A Comprehensive Treatise
general editors: **Roslyn Alfin-Slater** and **David Kritchevsky**

This major treatise authoritatively examines the present state of knowledge concerning human nutrition and its relation to all aspects of health and disease, covering both basic research and field application.

Volume 1
Nutrition
Pre- and Postnatal Development
edited by **Myron Winick**
Columbia University
516 pp., illus., 1979, $39.50 ($47.40/£24.89 outside US)

Volume 2
Nutrition and Growth
edited by **Derrick B. Jelliffe** and **E. F. Patrice Jelliffe,**
University of California, Los Angeles
472 pp., illus., 1979, $37.50 ($45.00/£23.63 outside US)

Volume 3
Nutrition and the Adult
edited by **Roslyn Alfin-Slater**
University of California, Los Angeles
and **David Kritchevsky**
The Wistar Institute, Philadelphia
in two parts
Part A
Macronutrients
approx. 300 pp., illus., 1979, $25.00 ($30.00/£15.75 outside US)
Part B
Micronutrients
approx. 500 pp., 1979, $39.50 ($47.40/£24.89 outside US)

Volume 4
Nutrition
Metabolic and Clinical Applications
edited by **Robert E. Hodges**
University of California, Davis
498 pp., illus., 1979, $37.50 ($45.00/£23.63 outside US)

Advances in Nutritional Research
Volume 2
edited by **Harold H. Draper**
University of Guelph, Canada
The second volume in this series presents advances in a variety of research areas. Topics covered include the role of nutrition in carcinogenesis, atherosclerosis, osteoporosis, and susceptibility to infection, and the regulation of energy metabolism in ruminants.
263 pp., illus., 1979, $27.50 ($33.00/£17.33 outside US)

Evaluating the Impact of Nutrition and Health Programs
edited by **Robert E. Klein**
Pan American Health Organization, Guatemala
Merrill S. Read
Pan American Health Organization, Washington, D.C.
Henry W. Riecken
University of Pennsylvania
James A. Brown, Jr.
U.S. Agency for International Development, Washington, D.C.
Alberto Pradilla
Foundation for Higher Education, Cali, Colombia
and **Carlos H. Daza**
Pan American Health Organization, Washington, D.C.
This volume explores the potential indicators of the impact of various food and nutrition plans in the Western Hemisphere. Equal attention is given to the practical problems of establishing impact evaluation systems, and the sociopolitical environment in which they must exist.
476 pp., 1979, $29.50 ($35.40/£18.59 outside US)

Cancer, Stress, and Death
edited by **Jean Taché, D.Sc.**
and **Hans Selye, C.C., M.D., Ph.D., D.Sc.**
International Institute of Stress, Quebec, Canada
and **Stacey B. Day, M.D., Ph.D., D.Sc.**
Sloan-Kettering Institute for Cancer Research, New York
Correlating scientific studies on cancer, stress, and death, this volume examines psychophysiological aspects of cancer, patient attitudes, and the effects of aging. A volume in the *Sloan-Kettering Institute Cancer Series.* 256 pp., illus., 1979, $22.50 ($27.00/£14.18 outside US)

Biochemistry and Pharmacology of Ethanol
edited by **Edward Majchrowicz**
National Institute on Alcohol Abuse and Alcoholism, Rockville, Maryland
and **Ernest P. Noble**
University of California at Irvine
in two volumes
"This is the best reference book on the subject . . . I find it most useful to have the different aspects of the biochemistry and pharmacology of ethanol covered by one work. The editors have succeeded in enlisting the collaboration of some of the leading experts."
—**H. A. Krebs,** *Metabolic Research Laboratory Nuffield Department of Clinical Medicine, Oxford, England*
Volume 1: approx. 700 pp., illus., 1979, $47.50 ($57.00/£29.93 outside US)
Volume 2: approx. 575 pp., illus., 1979, $42.50 ($51.00/£26.78 outside US)

Mykologisches Wörterbuch
— 3200 Begriffe in 8 Sprachen —

(Deutsch, Englisch, Französisch, Spanisch, Lateinisch, Tschechisch, Polnisch, Russisch)

Bearbeitet von 8 Fachwissenschaftlern. Herausgegeben von Dr. phil. KARL BERGER, Gatersleben.

1979. Etwa 370 Seiten, 138 Abbildungen auf 13 Tafeln, 17 cm x 24 cm, Leinen, etwa 78,—M. Best. — Nr.: 533 049 2.

Erstmals wird hiermit ein Fachworterbuch vorgelegt, das Termini der deskriptiven und angewandten Mykologie in 8 Sprachen tabellarisch zusammengefaßt bringt. Mit Hilfe der 7 fremdsprachigen Register kann man von jeder der 8 Sprachen ausgehen.

Pflanzenantomisches Praktikum I
Einführung in die Anatomie der Vegetationsorgane der höheren Pflanzen

Von Doz. Dr. rer. nat. habil. WOLFRAM BRAUNE und Dr. rer. nat. ALFRED LEMAN, Jena

3. bearbeitete Auflage. 1979. Etwa 340 Seiten, 94 Abbildungen in 417 Einzeldarstellungen, Randleistenschemata auf 34 Seiten, 17 cm x 24 cm, Leinen, etwa 33, — M. Best. — Nr.: 532 954 7

Auch diese Auflage erfuhr weitere Verbesserungen: Der gegenwärtige Wissensstand wurde berücksichtigt und die Terminologie aktualisiert. Das Bildmaterial wurde erheblich durch instruktiveres ersetzt.

Allgemeine Mikrobiologie

Von Prof. Dr. sc. nat. HEINZ WEIDE, Graifswald, und Prof. Dr. sc. med. HARALD AURICH, Halle (Saale)

1979. Etwa 600 Seiten, 300 Abbildungen, 47 Tabellen, 17 cm x 24 cm, Leinen, etwa 49, — M. Best. — Nr.: 532 953 9

Das Lehrbuch wendet sich primär an Studenten biologischer und biochemischer Studienrichtungen. Es geht aber in machen Kapiteln über den Charakter eines Basiswissen vermittelnden Lernbuchs hinaus. In jedem Abschnitt wurde ein ausgewogenes Verhältnis von Verallgemeinerungen und speziellen Beispielen angestrebt. Der Stoff gleidart sich in "Allgemeine chemische Strukturen der Zellbausteine", "Morphologie und Zytologie", "Stoffwechsel", "Wachstum", "Genetik", "Systematik" und "Angewandte Mikrobiologie". Die zahlreichen Abbildungen erleichtern den Zugang zum Text.

impossible to homogenise this environment. And it's as well it couldn't happen, for the only hope for evolution is for the race to have options to be matched against diversity. There's a deep wisdom in the phrase "trial and error"; we don't say (Thomas reminds us) "trial and rightness" or "trial and triumph".

One theme in these essays is to praise uniqueness. The other is to praise symbiosis and cooperation. Uniqueness does not spell solitude. The individuals cannot express their selfhood except in some sort of communication with other individuals. The committee, the quorum, the consortium, the working party: these are not specifically human devices for getting things done — they were invented long before by all manner of lowly organisms. Collaboration between organisms of the same kind and symbiosis between organisms of different kinds are so widespread that it leads Thomas to say that "the committee is the basis of terrestrial life". This carries him, at a safe distance from sociobiological analogies, to a discussion of the behaviour of committees of human beings. He has some penetrating things to say about the way we behave on committees. Each member, being unique, "is necessarily an actor, uncontrollably acting out the part of himself, reading the lines that identify him, asserting his identity". This is an obstacle to the efficacy of human committees, not shared by consortia of ants or termites. Each member's function, Thomas says, is to talk, "and while other people were talking the individual member was busy figuring out what he ought to say next in order to shore up his own original position". With more confidence than I myself have, Thomas advocates the Delphi technique invented by the Rand Corporation. His support for it rests on good grounds, namely that the members don't meet; instead they fill out a succession of forms, on which their views are (so it is hoped) modified by the written views of other members of the group. Hence the group members are not in competition to uphold their selfhood; instead they have time to think. Well, perhaps so. But this is surely to overlook another principle governing Nature, namely that decisions, whether consciously made by human beings or unconsciously reached by the mechanism of evolution, are the results of conflicts; and to hold a conflict one has to have an arena, even if it is a committee room.

I have space only to mention a few other flashes of illumination in the book. Thomas knows a lot about linguistics and he points out the difficulties of discussing the meanings of words when the tool for research is words themselves. There is a sort of Heisenberg effect which may distort the argument. Over the applications of science to medicine he is an unashamed optimist. He deplores the American obsession with health: "Get a check-up. Go on a diet. Meditate. Jog". Jogging particularly riles him: "swarms of people, out onto the streets each day in underpants, moving in a stolid sort of rapid trudge, hoping by this to stay alive". Why have people lost confidence in the human body, which has survived plague, starvation, pathogens, and is now better protected from these than ever before in all history? Thomas attributes this obsession in part to the ministrations of an immensely costly health care service.

The book, as I said, is about its author. The scientific content is merely the fuel which ignites his imagination. The personality that emerges is not entirely consistent nor is the argument always entirely logical. Thomas himself will, I think, welcome this comment, for in an essay about schizophrenics he protests that far from being a dreadful thing to have more than one self, it can (if the selves do not crowd into the body at the same time) be a rich experience; and indeed Thomas confesses to being several selves, so he would not wish to be thought to be consistent. And as for logic, Freud had the answer to that one: "Only in logic are contradictions unable to exist; in feelings they quite happily continue alongside one another". □

Florey's creative power

E.P. Abraham

Howard Florey: The Making of a Great Scientist. By Gwyn Macfarlane. Pp.396. (Oxford University Press: Oxford and New York, 1979.) £7.95.

THIS book is an authoritative biography of Lord Florey in his early and middle life. It is a tribute to a man who had a central role in the story of penicillin and became one of the great figures in the history of medical science. It is also a product of the persistence of Gwyn Macfarlane, who was told by publishers that an unknown author could not expect to see his biography of a scientist in print unless his subject was already famous in the public mind; and that although Fleming was a household name, Florey was not. Why this was so and how a myth was created are finally discussed in detail. A major theme of the book, however, as its sub-title implies, is the development of Howard Florey as a scientist and the factors that contributed to his success. "To be a great scientist", the author states, "one must (among other things) be a pioneer, a discoverer, a dedicated research worker, and one must be successful"; and he sets out to show how Florey came to fall within this definition.

In his assessment of Florey's character the author, unlike earlier biographers, has quoted from letters that Florey wrote from England and America to Ethel Hayter Reed, a fellow medical student in Adelaide, with whom he thought he had fallen in love. They were referred to later by Ethel as love letters, but *eros* scarcely appears in them although *agape* is sometimes seen. Some of the extracts from this correspondence, between two young people who were fourteen thousand miles apart, seem strangely cautious and business-like. But even those who know the outcome may have a sense of drama and begin to wonder whether marriage will eventually result or not, as problems, difficulties and requirements are laid on the table.

In the event, they married on 19 October 1926 in London a few weeks after Ethel's arrival from Adelaide. The marriage began badly and it was immediately evident that they were unlikely to be perfect partners. She was an attractive woman with intelligence and charm who could write to him on the boat "Do you realise that I shall arrive in England on your birthday: I shall wrap myself up in tissue paper tied with pink ribbon . . . will you accept the present or throw it into the sea?". Yet she was strong willed and difficult to live with and she had written of marriage as an ordeal. He, like many other young men, had ambition, impatience, idealism and private worries about his capability. They were both unduly concerned by thoughts of a lack of money and, with her, fear of poverty seemed to become almost an obsession. Neither had formed positive views of the nature of their relationship. While he had disclaimed any wish to impede her professional life or press her into domesticity, he had also written: "Married women messing about in labs always appear to be slightly pathological to me".

The marriage was not devoid of affection and there were intervals of contentment which coincided with the birth of two children. But it is clear that he did not find in her the ideal companion of his imagination and that some of her own premarital forebodings became realities. He was exasperated by her increasing deafness; yet other marriages have been happy in the face of greater impediments and the reader is left to wonder whether deeper problems were unresolved.

No general principles to guide the young who aspire to become great scientists are likely to emerge from this topic in the letters, for creative power seems to have been unleashed in some men and stifled in others by emotional frustration. There can be no doubt that Florey's epistolatory attachment to Ethel gave him great comfort during his early years in England, when feelings of loneliness sometimes became acute, and that it removed temptation to indulge in diversions which could have interfered with his great enthusiasm for research. But the relevance of his subsequent dissappointment to his great achievements is a matter for speculation — a process of which Florey himself was not much enamoured.

The Florey letters, however, also provide a diary of his early years in Oxford, where he obtained a first class in the Honour School of Physiology, and then in Cambridge, America and London. They describe the experiments he had done and intended to do with laboratory animals on the capillaries, the lymphatics, the omentum and mucus secretion. They tell of his emotional response to music and to the architectural achievements of past centuries and give the critical views of a young Australian on the English society of the day. They contain accounts of his meetings with a number of the great or then powerful figures in preclinical medicine, including Charles Sherrington, A.R. Dean, Edward Mellanby and J.B.S. Haldane. And they show that Florey's poor view of the intellectual content of much clinical teaching and of the quality of clinical research had been formed by the time he had qualified in medicine at Adelaide. All this Gwyn Macfarlane brings together in an admirable manner.

It was Sherrington who suggested to Florey that the time had come for an approach to pathology by a physiologist. Sherrington, Dean and later Mellanby were much impressed by his ability and energy in research and their support helped him to obtain positions at Cambridge and the London Hospital and then Chairs at Sheffield and Oxford. The Professorial appointments were made in the face of powerful opposition, for Florey was not regarded as a pathologist by the morbid anatomists who dominated the profession; Macfarlane tells the well-authenticated story of Mellanby arriving late at a crucial meeting of the electoral board in Oxford to find that it had already been decided to offer the chair to another candidate and of his ability to persuade his colleagues to change their decision. He goes on to describe Florey's frustration during his early years in the Sir William Dunn School of Pathology, his fight for what would now seem to be trivial sums of money for research and his disappointment at finding that the great Nuffield benefaction of 1936 would provide a rich endowment for clinical medicine in Oxford, but do nothing for the pre-clinical departments. But Florey rapidly invigorated what was a nearly moribund Department. He continued his work on mucus secretion and on lymph flow and the function of the lymphatic system. A later outcome of his interest in lymph, when labelling with radioisotopes and other new techniques had become available, was the important discovery by J.L. Gowans of the circulation of the lymphocyte.

Florey's work in these fields, often requiring surgery of great skill and designed to obtain unambiguous answers to straightforward questions, virtually established the subject of experimental pathology in this country. This was one of his great achievements.

The book describes how the research on mucus secretion, which originated from anxiety about his own dyspepsia, led indirectly to penicillin. While still at Cambridge, Florey had become interested in Fleming's lysozyme, probably because the presence of this bacteriolytic enzyme in intestinal mucus raised the question whether lysozyme, or a related antibacterial enzyme, was responsible for the protective action of the mucus. His wish to have lysozyme purified seems to have prompted the thought that experimental pathology would benefit from a collaboration of pathologists with chemists or biochemists. But it was only after he became Professor of Pathology in Oxford that he succeeded in obtaining the funds for a biochemist to work in his Department. It was thus that Ernst Chain, a Jewish refugee from Hitler's Germany who had just finished his PhD at Cambridge and was warmly recommended by Gowland Hopkins, came to the Sir William Dunn School of Pathology in 1935. He worked at first on the mode of action of snake venoms and then, at Florey's suggestion, he turned his attention, with L.A. Epstein, to the mode

Howard Florey

of action of lysozyme.

It has never been possible to write a history of penicillin that would have satisfied all of those who were closely concerned. But in most of its essential features Gwyn Macfarlane's well documented version probably comes as near to the truth as anyone is now likely to get, and it is only his treatment of some of the chemical studies which is open to question. He devotes one chapter to Alexander Fleming and the extraordinary conjunction of chance events (analysed by Ronald Hare in *The Birth of Penicillin;* George Allen and Unwin: London, 1970) that made it possible for him to discover penicillin in 1928. Why Fleming made no attempt to test its ability to cure bacterial infections in mice, as he could have done, is a question to which he never gave a satisfactory answer. There is no evidence for the suggestion of André Maurois, his biographer, that he was actively discouraged by his chief, Almroth Wright. His claim that he lacked chemical help is unconvincing, because he showed little interest in the work of two young assistants, Ridley and Craddock, who prepared crude extracts of penicillin, and none at all in the later and soon abandoned attempt at isolation by Raistrick, Clutterbuck and Lovell. It seems that the idea of using penicillin as a systemic chemotherapeutic agent simply did not occur to him, nor did it occur to such influential figures as Wright and Topley But Gwyn Macfarlane rightly says "Fleming should not be criticised for what he did not do" and concludes that his genius for discovery was not accompanied by the sort of character needed to exploit what he found.

Ten years after Fleming's discovery, an investigation of penicillin was begun in the Sir William Dunn School of Pathology, as Chain's work on the substrate of lysozyme led him to make a survey of the older literature on bacteriolytic substances. "Dr Chain and I", wrote Florey, "had many discussions on the possible interest of a systematic and thorough study of the known natural antibacterial substances"; and later he said: "eventually he proposed, and I agreed to go along with it, that we should make a thorough investigation of antibacterial substances. This is why we looked at penicillin". Chain's biochemical interest in penicillin was aroused by its reported instability and Florey was struck by its activity against the staphylococcus, against which the sulphonamides had proved relatively ineffective. However, penicillin was only one of three substances first chosen for study and was at first given no particular prominence. Gwyn Macfarlane leans towards the view that thoughts of "suffering humanity" lay behind the decision to work on penicillin. Florey, however, has stated categorically that this was not the mainspring of the motivation, which was scientific interest, and he did not fail to acknowledge the role of chance: "We happened to hit on an antibiotic which worked in man. We could have worked with hundreds of others and they would have been chemical curiosities".

Florey always maintained that the success of the penicillin project itself, which seemed at the time to be almost miraculous, was due to the combined work of a small group: "I am quite clear that nothing would have gone along except for a group of five or six people". Gwyn Macfarlane gives handsome bouquets to all those concerned in a detailed account of the extraction of penicillin and the dramatic results obtained from well-planned experiments by Florey, first in mice and then in man. But he rightly concludes that it was only Florey's drive and personality that held the group together, and enabled difficulties to be overcome which at first seemed insurmountable in war-time Britain.

Chain made no secret of his view that he had received too little credit and reward for his part in the penicillin story and that the Medical Research Council was guilty of a major error of judgement in not obtaining patent protection for the Oxford work on penicillin. But although it is now widely accepted that a policy which excludes the products of academic medical research from patent cover is a form of idealism that the country cannot afford, this was not so before and during the War. At Florey's suggestion, Chain went to Edward Mellanby, then Secretary of the Medical Research Council. However, Mellanby, who seems to have regarded him as an alien and troublesome personality, was unmoved. The official attitude became the subject of public criticism, but this may have been irrelevant, at least in relation to the achievements in Oxford, because it is by no means certain that a rewarding patent could then have been obtained. Although the results with penicillin were new and far-reaching, penicillin itself was not new and it had not been characterised chemically. The methods used in its production were soon to be superseded by others in America. The most important unpublished step in its

purification (extraction as a salt into water from an organic solvent), which was suggested in Oxford by N.G. Heatley, had already been taken (unknown to him) in 1934 by Lewis Holt, a chemist at St Mary's Hospital whose work was never mentioned by Fleming. Moreover, the penicillin produced later in the United States for clinical use (benzylpenicillin) differed in its side-chain from the penicillin then being studied in Oxford.

The book also contains comments on another aspect of this question. After the clinical trials at Oxford in 1941 Florey decided that American help would be essential for the war-time production of penicillin in quantity. With the agreement of the Medical Research Council and financial support of the Rockefeller Foundation, he and Heatley went to the United States to try to interest the American pharmaceutical industry. Penicillin, then only produced in minute quantities, was far from easy to sell, but Heatley was invited to the Fermentation Division of the Northern Regional Research Laboratory in Peoria to help get a project started. He worked with A.J. Moyer, described in the book as "a fervent anti-British isolationist" with a "positive flair for making moulds do what was wanted". Moyer and Heatley had agreed on a joint publication, but the paper which eventually appeared was in Moyer's name alone. During this time the outlook for penicillin production was revolutionised by the American decision to add corn-steep liquor to the growth medium and to use deep fermentation, and these advances became the subject of American patents. British firms were understandably irked when they discovered that they were required to pay royalties to America to produce a substance that was essentially a British discovery. But equity and patent law may sometimes diverge. At the root of the problem was the fact that the official pre-War world in Britain was entirely unprepared for a situation of the kind that penicillin threw up. And there is, of course, another side to the matter. Without American help it is inconceivable that enough penicillin would have been produced, as it was, to treat all serious battle casualties, British and American, when D-day came in Europe.

The penultimate chapter of the book is headed "Palmam qui meruit ferat", a phrase used by Almroth Wright in a letter to *The Times* on 31 August 1942 firmly placing a laurel wreath on Fleming's brow. The nature of the publicity that followed can be attributed partly to Florey's refusal to talk to the press, partly to the welcome given to the press by Fleming and others at St Mary's Hospital and partly to the unwillingness or inability of popular writers to acquaint themselves with the facts in the scientific literature. One of these stories, written by a bacteriologist at St Mary's and more ludicrous than others only in the extent of its fabrication, attributed virtually all that had been done in Oxford to Fleming himself. The source of this myth is uncertain, but Gwyn Macfarlane remarks that behind Fleming were Almroth Wright "intensely ambitious for his department" and Lord Moran, Dean of St Mary's Hospital Medical School "Whose dearest wish was for its honour, glory, and financial security" and suspects that an efficient Public Relations Officer was active somewhere in the organisation. Fleming himself is said to have derived an impish glee from the more bizarre stories as he collected cuttings, a reaction that might have been understandable had he not been gaining worldwide gratitude from their publication.

Florey complained of this situation to Edward Mellanby who replied that it was ephemeral and of little consequence and that "in time even the public will realise that in the development of this story of penicillin, the thing that has mattered most has been the persistent and highly meritorious work of your laboratory". There is now now reason to think that the publicity has ever affected the judgement of scientific bodies of any consequence, but its effect on the public has been far from ephemeral.

Gwyn Macfarlane finally summarises some of the qualities which combined to make Florey an outstanding figure: his great energy and enthusiasm for research; his skill as an experimenter and commitment to experiments that gave clearcut results; his judgement and sense of direction; and his complete intellectual integrity, never clouded by vanity. His colleagues who came to like and admire him will remember that behind a deep reserve there were kindness and consideration for their welfare. It is to be hoped that this well documented book will make his qualities and great contributions to science and medicine more widely known. □

E.P Abraham is Professor of Chemical Pathology in the Sir William Dunn School of Pathology at the University of Oxford, UK.

Olduvai record

J. Desmond Clark

Olduvai Gorge: My Search for Early Man. By Mary Leakey. Pp. 181. (Collins: London, 1979.) £6.50.

EAST AFRICA remains unsurpassed in the wealth of discoveries and the understanding these provide about the biological and cultural evolution of our own species. It is no exaggeration to say that the very impressive record of hominid fossils and cultural remains in their palaeo-environmental setting that has come from East Africa and the Horn over the past twenty years, has revolutionised our knowledge of human phylogeny. The hundreds of fossil hominid remains recovered, often remarkably complete and well preserved, and the circumstances of their preservation have made it possible to identify some of the behavioural adaptations that underlie the beginnings of tool-making and the ensuing intellectual development manifest in the increasing complexity of the tool-kits and the economic strategies that gave rise to them.

A very great deal of what is known today results from the lifetime devoted by Louis and Mary Leakey to their search for early man — a search which has completely vindicated Louis' claim, first made when he was an undergraduate at Cambridge in the 1920s, that a wealth of evidence awaited discovery in the deep sedimentary sequences of the Great Rift Valley. It was really the first full season's work in 1935 at the Olduvai Gorge in northern Tanzania, which was also Mary Leakey's introduction to fieldwork in the African Quaternary, that was the first demonstration of the correctness of Louis' conviction. It was also the first manifestation of his shrewdness — some would say his luck — in having concentrated on the Rift which, as can now be seen, is probably the most significant region in the world for preservation of the Plio-Pleistocene record that spans the emergence and early development of man the tool-maker.

The fossil, geological and cultural evidence is unique, both in its completeness and in the relatively minor disturbance that it has suffered. This has made it possible to reconstruct the changing climatic and ecological conditions under which hominid evolution took place, to find and excavate the activity places of the hominids, and to date all these events. In the 1930s, there was no way of knowing how old the then earliest fossils and stone tools were. At that time Keith's 'guesstimate' of 200,000 to 400,000 years did not seem unreasonable to many and, indeed, most people then thought in terms of half a million or so years for the beginning of the Pleistocene. Now, K/Ar, uranium fission-track dating and the palaeomagnetic reversal chronology show that the earliest stone tools are about 2 million years old; that the earliest, well-known hominid (*Australopithecus afarensis*) is between 3 and 4 million years old; and that even earlier, but fragmentary, remains are present in the East African sedimentary record. From the 1960s onwards, a number of interdisciplinary and international teams have been working in the East African and Ethiopian sections of the Rift and on the adjacent parts of the plateau — for example, at Laetoli, Olduvai, Omo, East Turkana, Hadar, and on the

Ethiopian Plateau. The discoveries and information that this work is producing are of paramount significance and there is every expectation that, as the research continues, an even greater wealth of material, detail and clarification will result.

Dr Mary Leakey's contribution to all this is both very substantial and outstanding in its importance. It was she who pioneered and introduced to Pleistocene prehistory the methods of excavation, recording and recovery that are common practice today. A meticulously careful and observant fieldworker, Mary Leakey found that activity areas were still preserved within the fine-grained sedimentary sequences in the East African Rift where she and Louis worked. She was also the first to demonstrate the existence of these early sites and to apply to them the methods used by archaeologists in the excavation of settlements of much more recent times. By exposing the whole, or large parts of an occupation area to give a complete visual perception of the relationships between all the imperishable residues — artefacts, bone waste, features, hominids, and so on — in their palaeotopographical setting, palaeoanthropologists now have the opportunity of making direct comparisons with the residues resulting from various accumulating and dispersing agencies — geological, chemical, animal or human — and therefore of developing explanatory models for early hominid behaviour.

Since 1959, when she found the first hominid cranium (*Australopithecus boisei*) in Olduvai Gorge, Mary Leakey has worked there almost continuously; and since 1968, she has made her permanent home at the Gorge. The scientific results of her work are recorded in the classic Volume 3 in the Olduvai Gorge Series (*Olduvai Gorge: Excavation in Beds I and II, 1960-1963;* Cambridge University Press, 1971) which is shortly to be followed by a volume on the discoveries in Beds III and IV and the later sediments. Obviously, such works are not the place in which to record some of the more personal events of everyday life at Olduvai — always exciting and packed with activity.

The present book is an attempt to make up for this by telling something of camp life at Olduvai and the way the work there has progressed through her own systematic fieldwork and that of the team of collaborators who have been working with her on the geology, palaeontology and chronology of the Olduvai sedimentary sequence that began two million years ago. For someone wishing for an overall appreciation of the setting in the Serengeti, a record of the main discoveries with something of their significance and an account of some of those involved with the author in the work at Olduvai, the book admittedly fills a need. It is divided into eight chapters, the first seven dealing with the early discovery of the Gorge; camp life; geology, dating and excavation methods; the stratigraphic sequence of sites in their geological setting; the search for the hominids; the nature of the stone artefact assemblages, with a very usefull illustrated glossary of terms; the associated animal remains; and the evolutionary changes which the Olduvai record shows that some of these underwent.

Mary Leakey at the site of WK East in Bed IV at Olduvai

Photo: J. Desmond Clark, 1972

The book, however, will not entirely satisfy the reader who looks for a more personal account of the life and work at Olduvai — the problems, stresses, excitements, frustrations and successes of the author's life and search. Her interest in the natural setting, the vegetation and the animals is readily apparent but some readers might, for example, have appreciated a description of the view from the camp dining room following the remark (page 23) that it is magnificent. Similarly, more might have been made of the opportunity to describe the Masai way of life. The layman would also, no doubt, have found it useful to have had more of the scientific names of the animals, and so on, explained in chapter 7.

On the other hand, the description of the prehistoric living sites and stone tools well conveys the author's particular interest in this part of the work and describes the way in which a living site is laboriously uncovered. Also, some of the excitement and rewards of the work are conveyed by the account of the stone circle which portrays the earliest man-made structure yet known and which was found at the base of the more than 350 foot sedimentary sequence, and also by the description of the more enigmatic "pits" on a later site. More space might have been given to an account of the butchery sites but prehistorians will find valuable the previously unpublished data on Beds III and IV and the later series of beds.

Regrettably, the hominid footprints found at Laetoli receive hardly more than passing mention and, even though Laetoli is a short way distant to the south of Olduvai, more space might surely have been devoted to this momentous discovery which provides proof of the bipedal nature of Pliocene man.

In the concluding chapter, Dr Leakey discusses the significance of the East African evidence and the great potential that exists there for increasing understanding of the ways of life of the earliest hominids. As she points out, the evidence coming from the African continent is today the most complete for this time period anywhere in the world; this can, in part, be explained by the unique circumstances of preservation and the continuity of research there. The opportunities for fieldwork as well as the circumstances under which fossils were preserved and the possibilities of dating them have not been so good in the Asian tropics. It is, nevertheless, essential to know if an equally long record of hominid evolution also exists there; and it is to be hoped that the field studies now under way will provide at least part of the answer, through the kind of teamwork which has proved so successful at the Olduvai Gorge and which is revealed in this book.

Although the book does not really do justice either to the enthusiasm or the known achievements of its author, it does contain much of interest to all kinds of readers. It remains a record of more than forty years of unparallelled devotion to the search for early man. □

J. Desmond Clark is Professor of Anthropology at the University of California at Berkeley. Professor Clark has known Mary Leakey since 1941, and has worked with her many times since then.

Memories of Sherrington

C.G. Phillips

Sherrington: His Life and Thought. By J. C. Eccles and W. C. Gibson. Pp. 269. (Springer International: Berlin, Heidelberg and New York, 1979.) DM34.

SHERRINGTON died in 1952. Within ten years a young collaborator of Ragnar Granit's was confessing that his generation knew nothing about him. Granit's answer was that many of the conceptual foundations of their research were created in Sherrington's mind. His *oevre* is remarkable for its sheer coherence. Discoveries and rediscoveries fall into place in an almost continuous narrative, as can be seen in Denny-Brown's *Selected Writings of Sir Charles Sherrington,* now reprinted by Oxford University Press for the Guarantors of the journal *Brain.* These, together with *The Integrative Action of the Nervous System* (1906) and the last chapter of *Reflex Activity of the Spinal Cord* (re-issued recently by Oxford University Press on D.P.C. Lloyd's initiative), are all readily available to anyone who wishes to know and value Sherrington's achievement. He was evidently concerned to leave his scientific testament in good order. Many will wonder at his highly individual literary style, seemingly so contorted in places and contrasting so strongly with the plain English in which he wrote the letters and reminiscences now published in Eccles' and Gibson's book. One has to remember that he was striving to express ideas which were not yet familiar to his readers. R.S. Creed in his memoir explains that Sherrington's first care was to escape ambiguity and to be concise, rather than to be immediately intelligible. The contortions were not casualties of confused thinking, but the result of deliberate rewriting, often delayed by the search for some crucial word. On these foundations neuroscientists are still building, usually as unconsciously as Granit's pupil. Though modest in manner, Sherrington was not quite without vanity: Denny-Brown has told how he "shyly" produced Hamburger's comment (which prefaces *Selected Writings*) that anyone who had witnessed his demonstration of reciprocal inhibition in a monkey at the Fourth International Congress of Physiologists in 1898 "a enrichi sa connaissance pour toujours". But in his preface to the re-issue of the *Integrative Action* (1947: extracts reprinted by Eccles and Gibson) he referred to it as "my rather elderly book". To J.F. Fulton he wrote (when he had just retired, in his late seventies): "Thank you for mentioning again that the old *Integrative Action* still floats. I know how generously you regard it, and am very grateful. But looked at rigidly I cannot but recognise that it has "had its day". Its best future is for what lives of it to be incorporated — unobtrusively — into what is written with similar scope, now and after, for a time". At about the same period, in his review in *Nature* of Romón y Cajal's autobiography, he quoted the "wistful" passage in which his old friend, whose structural work on the neurone had always complemented his own physiological work, accepted that "the facts associated at first with the name of a particular man end by being anonymous, lost for ever in the ocean of Universal Science. The monograph impregnated with individual human quality becomes incorporated,stripped of sentiments, in the abstract doctrine of the general treatise. To the hot sun of actuality will succeed the cold beams of the history of learning". Sherrington's comment: "We may express this in short by saying that, as Aristotle thought of the soul, a scientific writing has no personal immortality". Yet active scientists do sometimes go to the writings of their forebears for inspiration — a *creative* act of ancestor-worship.

C.E.R. Sherrington, in his Memories now published by Eccles and Gibson, wrote that his father was averse to the idea of any "extensive biography". Sherrington's pupils have respected this wish. In formal memoirs, written at the time of his death, they have recorded the facts of his career and the people who helped and influenced him. Of these memoirs, that by E.G.T. Liddell, in the Royal Society's series, is the acknowledged masterpiece. Liddell's homage took the form of a remarkable book, *Discovery of Reflexes,* in which, with the insights of a neuroscientist as well as those of a scholar who reads seventeenth-century Latin as well as French and German, he painted a splendid landscape of knowledge and ideas about the nervous system at the time when Sherrington began to publish in 1884. This sets in relief the veritably Harveian revolution which Sherrington brought about. Ragnar Granit's *Charles Scott Sherrington: An Appraisal* tells of the modern experimental exploitation of Sherrington's seminal discoveries and concepts: the synapse; central inhibition as an active process; convergence and interaction of excitatory and inhibitory synaptic inputs at the neuronal membrane; receptor organs in muscle and their reflex actions, as proof of their continuing vitality. Eccles and Gibson have also respected Sherrington's wish, though a sentence at the beginning of their Preface (not to mention "the definitive Sherrington biography" proclaimed by the publisher's dust-jacket blurb) might have alarmed him. "More and more, students of history are calling for creative writing on the whole man, particularly when he is a genius. Those interested in the genesis of ideas want to know the settings for discoveries and the relevant circumstances which ushered in new truths and insights". "Creative writing on the whole man" suggests imaginative reconstruction of feelings and motives and of intimate personal relationships. His visits to Eastbourne left Liddell in no doubt about Sherrington's feelings in his very old age. "Hardly ever, he felt, can a biographer discern and interpret the inner thoughts which have moved the mind of another man years before. The mind made the man, and its achievements alone are worth recording". But Eccles and Gibson's wholly delightful book is not that sort of biography. In the first place, getting on for one-third of the words are those of Sherrington himself, a charming anthology of writings relating largely to life outside the laboratory. In the second, the well-known landmarks of his career are freshly illuminated by quotation from a large collection of letters, which, together with other Sherringtoniana, are housed in Professor Gibson's Department of the History of Science and Medicine in the University of British Columbia. Thirdly, both authors worked in Sherrington's laboratory at Oxford, and now add their personal witness to that of the others who shared in the action during his last years, when, in his seventies, he had steered his reflex experiments away from their significance as items of adaptive behaviour and into the neuronal basis of their physiological production and execution, and had brought them to their zenith of technical refinement and quantitative precision.

The Preface says that the book will concentrate on themes that have been "but lightly touched on" by previous writers. One only of its promises is not performed: one finds nothing about any analysis by Sherrington of the lack of productivity of British medical science at the end of the nineteenth century. For readers whose first love is to do experiments, Eccles' story of his exciting years with Sherrington in the 1920s and 1930s will be the highlight of the book. They were counting the muscle-fibres in the motor units and estimating their average contractile force. (The cautionary tale of the "muscle angle" comes in here). The motor nerves had to be emptied of afferent axons by antecedent dorsal root ganglionectomy. Sherrington was not only skilled in this delicate operation, but was also responsible for the perfectly circular and uncrinkled appearance of the myelinated motor axons in transverse sections; he dehydrated the splinted nerves overnight in his bathroom at home, and spent many happy hours in teasing nerves in order to prove the branching of motor axons. They noted the two peaks in the axon diameter spectrum, but inexplicably, in view of their awareness of the motor innervation of muscle spindles and of Sherrington's discussion of its possible significance in his Linacre Lecture

NEW GEO BOOKS FOR OUR TIMES

Ground Freezing

edited by H. L. JESSBERGER

(Developments in Geotechnical Engineering, 26)

Contains the proceedings of the First International Symposium on Ground Freezing held in Bochum in March 1978. The application of the ground freezing technique in geotechnical engineering has increased rapidly throughout the world in recent years and this symposium provided international scientists with the opportunity of exchanging information about engineering with frozen soils and related frost research problems.

1979 viii + 550 pages US $78.00/Dfl. 160.00
ISBN 0-444-41782-6

Elastic Waves in the Earth

by WALTER L. PILANT

(Developments in Solid Earth Geophysics, 11)

Based on a one-year course taught to graduate students at the University of Pittsburgh, here is an advanced textbook on theoretical seismology which provides a complete and up-to-date account of elastic wave propagation.

1979 xii + 494 pages US $48.75/Dfl. 100.00
ISBN 0-444-41798-2

Geosounding Principles, 1

Resistivity Sounding Measurements

by OTTO KOEFOED

(Methods in Geochemistry and Geophysics, 14A)

During the past decade, tremendously important innovations have been made in the methods of interpreting resistivity sounding data, and the advent of smaller, cheaper computers and calculators has made accurate interpretation possible at a reasonably low cost. This book is the first to incorporate all these developments and it will be invaluable both to researchers and to those who apply the resistivity sounding method in practice.

Fundamentals of Reservoir Engineering

by L. P. DAKE

(Developments in Petroleum Science, 8)

TEXT BOOK

"There have been few books published covering Reservoir Engineering since the classic by Craft and Hawkins 'Applied Petroleum Reservoir Engineering' which has been the standard text in the industry since 1959. This book by L. P. Dake may well take its place. It gives a clear up-to-date account of the basics of Reservoir Engineering, starting with the essential physics and leading on to the theory and practice of oil and gas well testing, pressure analysis methods and finally water influx and fluid displacement techniques. The text is clear and is well illustrated by worked examples. Our students have found it most useful."

- Dr. R. A. Dawe, Lecturer in Petroleum Engineering at the Imperial College of Science & Technology, London

1978 2nd repr. 1979 xvi + 444 pages

The Generic Names of Moths of the World

The aim of this series is to provide a complete list of all the generic names, their type-species, designations, and appropriate references, for each of the families of moths treated. By ensuring that each generic name has its type-species fixed in accordance with the *International Code of Zoological Nomenclature*, this series should rectify present confusion and form a basis for a more stable nomenclature. All generic names have been checked for homonymy, and if necessary replaced.

The series is a companion to *The Generic Names of the Butterflies and their Type-species* by F. Hemming. It is expected to run into some seven volumes which will not necessarily appear in numerical order.

Volume 1; Noctuoidea (part): Noctuidae, Agaristidae and Nolidae.
By I. W. B. Nye
1975 Pp. viii+568 frontispiece Crown Quarto Cloth.
ISBN 0 565 00770 X £26.00

Volume 2; Noctuoidea (part): Arctiidae, Ctenuchidae, Dioptidae, Lymantriidae, Notodontidae, Thaumetopoeidae and Thyretidae.
by A. Watson, D. S. Fletcher and I. W. B. Nye.
Publishing 1980

Volume 3; Geometroidea: Apoprogonidae, Axiidae, Callidulidae, Cyclidiidae, Drepanidae, Epicopeiidae, Epiplemidae, Geometridae, Pterothysanidae, Sematuridae, Thyatiridae and Uraniidae.
by D. S. Fletcher.
Publishing late 1979 price about £20.00

The companion volume

THE GENERIC NAMES OF THE BUTTERFLIES AND THEIR TYPE SPECIES
by F. Hemming
Bulletin of the B.M. (N.H.) Entomology Supplement No. 22.
1967 (reprinted 1972) 509 pp. 4to paper covers. £22.00

A STANDING ORDER placed now will ensure that you are kept informed of forthcoming volumes. As each is published you will receive a pro forma invoice informing you of the cost. Your copy will be forwarded on receipt of payment.

in 1924, failed to suggest that the smaller-calibre group was fusimotor. Then came the long series of experiments on the interaction of excitatory and inhibitory reflex imputs, testing Sherrington's already-published theories and leading up to their culminating statement in the final chapter of *Reflex Activity of the Spinal Cord*. The atmosphere of the laboratory comes to life as we learn how they recited Keats and Bridges during the routine preparations, how Sherrington spoke of such things as his belief that Verocchio's studio was like a modern research laboratory, and how, on those two strenuous days each week, they missed lunch but went into the town for an enormous afternoon tea before the final recording session.

Eccles' involvement in the mind-brain problem is well known, most recently from his book with K.R. Popper (*The Self and Its Brain;* Springer: Berlin; for review, see *Nature,* **272**, 770; 1978), and his Gifford Lectures have also been published by Springer this year as *The Human Mystery*. Sherrington thought deeply about the problem in his last years. In 1922, in his Presidential Address to the British Association (reprinted in an Appendix as *The Times'* report), he spoke in evolutionary terms of the "twilit emergence of mind from non-mind, which is repeated in the individual life-history". His Rede Lecture, *The Brain and its Mechanism* (1933) was "eagerly read" in the laboratory "as giving some glimpse of the philosophical thinking he had been developing unbeknown to us". In his Gifford Lectures, *Man on his Nature*, first published in 1940, and about which, also, he was "secretive" (or dismissive: to Fulton — "I fear they are *not* interesting") he developed these themes in a biological epic of Homeric stature, its whole conception and wealth of illustration the product, as Eccles well says, of one of the most cultivated minds of the modern world. The Lectures were on Natural (as distinct from Revealed) Religion, and the audience, mainly of clergymen, can have received little comfort. Supernatural explanations of biological phenomena — heredity, ontogeny, adaptation for survival — had been replaced by natural explanations or shown to be replaceable in principle. Animate nature is amoral and much of it can only be valued by moral beings as loathsome. Yet, though mindless, its products adapt to pressures which threaten survival in ways which seem purposeful. Then comes the gradual emergence of "recognisable mind", linked with the appearance of bigger and more complex brains, and conferring increasing domination of the environment and of other species. Eventually there appear aesthetic and moral qualities which give hope that altruism will supplant predatory behaviour. "It may likely mean a human future led by women more eminently than by men". Yet neurone and synapse seem everywhere the same; and, in spite of the essential unity of bodily and mental life, analysis finds *two* modes of activity, mind and energy — irreducibly. Confronted with this twentieth-century epic, different readers will respond differently. Eccles' response, as shown in the passages he has chosen and in his commentaries, follows the lines of his well-known books, but differs for example from Granit's (we may think) equally valid one. One can agree that Sherrington "embraces as equals all the values", but be puzzled by the statement (page 156) that he "even exalts altruism

Sherrington in 1950, aged 93

Photo: Allan G. Chappelow

above truth". One hopes that readers will be encouraged to go to the source. Schrödinger wrote: "I cannot convey the grandeur of Sherrington's immortal book by quoting sentences; one has to read it oneself".

Though deadlocked about how mind and energy interact in the brain, and unwilling to propose any hypothesis, Sherrington had written (in the Rede Lecture) "I am not a defeatist, for I would urge active pursuit of the enquiry", though "it seems to me, speaking in all humility, that from time to time the biologist has to make plain how far or near he is from the answer". If "man, the best among us", finds out "how the brain does its thinking", he "will certainly try to improve its ways of doing so . . . We need not be prophets to foresee that then will come the long-told speedy extinction of man. The planet will then be re-liberated, free for the next era of animal domination". Today it seems that the same danger could come from psychotropic substances discovered by chemists, whose control of thought and behaviour might bring extinction before neuroscientists have had time to discover "how the brain does its thinking".

Professor Gibson's quotations from his collection of letters illuminate the whole range of Sherrington's activities. As a professor, he never had a secretary, but wrote his many letters by hand and kept his files himself, with help from his wife. He could rely on an extraordinary memory. His letter of 1947, describing how his pioneering use of diphtheria antitoxin saved the life of his eight-year-old nephew in 1893 or 1894, is reproduced in facsimile. Although genial he could be firm when necessary — as when the Dean at Liverpool, an anatomist, tried to cut physiology by half and pathology by a third to gain more time for anatomy. He helped many people, notably Harvey Cushing, Wilder Penfield, Hugh Cairns and Howard Florey, in their careers. Private donors gave hime money for research. In thanking the British Medical Association for financial support, he drew public attention to the £4,000 per annum which in 1907 was all the Government gave to the Royal Society to support research in all fields in the whole of the British Empire. "The sum is about the same in amount as — sad to say — the average yearly takings of a public-house in a poor quarter of this city". He spent much trouble on public education and in service on committees — writing articles for the *Encyclopaedia Britannica*, six chapters for a manual of school hygiene, reports on health in schools, on the importance of longer hours of sleep in public schools, on tests for sight and colour blindness, and even on the infectivity of oysters. Partly to study industrial fatigue he worked during the long vacation of 1915 (he was 58) in a munitions factory. No-one knew who he was, and the foreman offered to write him a good testimonial. Asked by Alan Gregg of the Rockefeller Foundation about the function of modern Oxford, he replied that it could no longer rely on its centuries-old skills in teaching what is known, but "must learn how to teach the *best attitude* to what is *not yet* known. This also may take centuries to acquire but we cannot escape this new challenge, nor do we want to".

Gibson has a fine chapter on Sherrington the Poet, illustrated by several sonnets and extracts from longer pieces. His work was taken seriously by Hardy, Edmund Gosse and Walter de la Mare. An appendix reprints his undergraduate essay on Longfellow. There is a good deal of correspondence about his lifelong collection of incunabula — another interest about which he was ordinarily extremely reticent. His gifts to the British Museum marked him as its "best benefactor in modern times". Then there is his hilarious account of Christmas at Grindelwald in 1887. And so on. Having read it all you will want to browse frequently. □

C.G. Phillips is Dr Lee's Professor of Anatomy at Oxford and Editor of Brain.

Early days of behaviourism

O.L. Zangwill

J.B. Watson: The Founder of Behaviourism. By David Cohen. Pp. 297. (Routledge and Kegan Paul: London and Boston, 1979.) £8.95.

THIS is a biography of Watson; not a study of the origins of behaviourism. Nonetheless, Dr Cohen's well researched and highly readable book tells us a good deal about the early days of behaviourism, a school of psychology which Watson himself once spoke of with evident pride as "this purely American production". His account will do much to demolish the still popular myth that behaviourism amounted to little more than the export of conditioned reflexes from Russia to the United States and the substitution of muscle twitches for mind as the subject-matter of psychology. At all events, in so far as conditioned reflexes are concerned, Watson owed distinctly less to Pavlov than to his contemporary and rival, Vladimir Bechterev, whose correspondence with Watson may still be seen at the Bechterev Institute in Leningrad. Moreover, Pavlov himself made no secret of his detestation of behaviourism and ridiculed its pretensions to be a scientific discipline. Pavlov, of course, was a militant physiologist imbued with the materialist philosophy which he had brought from Germany, whereas Watson was a psychologist through and through, concerned only to establish a viable science of human behaviour. It is not surprising that relations between them were cool.

John Broadus Watson was born in 1878 in Greenville, South Carolina. His father was an impecunious farmer and his mother a pillar of the local Baptist community and a Fundamentalist who evidently ruled her family with a rod of iron. Following graduation from Furman University in 1899, Watson proceeded to the University of Chicago, where he came strongly under the influence of James Rowland Angell, a sometime student of William James' who favoured a biological, or as it was then termed 'functionalist', approach to psychology in contrast to the 'structuralist' approach of Wundt, with its emphasis on classification and introspective method, which Titchener and other early experimental psychologists had exported from Germany. Although Watson came later to disown 'functionalism' almost as radically as 'structuralism', he seems to have retained towards Angell himself a deep and abiding respect.

On Angell's advice, Watson began his graduate work in the field of comparative psychology. His PhD thesis, published in 1903 as a monograph under the title of *Animal Intelligence*, was largely concerned with the growth of learning capacity in the white rat, with special reference to the medullation of the nervous system. (The neurological aspects of this work owed much to the Chicago neuroanatomist, H.H. Donaldson, who evidently thought highly of Watson and to whose personal generosity he owed its publication.) In this study, it is noteworthy that Watson had no hesitation in using the concepts and nomenclature of introspective psychology, and it belongs much more closely within the 'functionalist' tradition than any of Watson's later publications.

Watson continued with his animal work at Chicago for several years and some of it has proved surprisingly durable. With Harvey Carr, he worked on spatial orientation in the rat, with special reference to kinaesthesis and the sensory control of maze learning. At this time, too, he first made the acquaintance of Karl Lashley, then still a graduate student, and collaborated with him in some early studies of bird behaviour. He also came to know Robert Yerkes, then a young physiologist at Yale, who became a firm colleague and friend. From Dr Cohen's account, it might be surmised that, had Watson remained in Chicago, it is by no means impossible that the scandal which was later to drive him out of academic life would have been averted.

In 1908, Watson became a full Professor of Psychology at Johns Hopkins University, and it was at Baltimore that behaviourism was born. No doubt the sympathetic biological climate of this University, and more especially its Medical School, contributed to this happy event, but by far the most important determinant was the advent of Lashley as a PhD student in zoology and psychology in 1911. Although Watson's background in animal psychology and, above all, his total disillusionment with the current schools of experimental psychology, no doubt touched off the behaviourist revolution, without Lashley it seems unlikely that behaviourism would have evolved as a credible competitor or achieved a measure of real scientific distinction. It was these two men working in close association who virtually created the behaviourist movement.

What, then, was the behaviourist position? This Dr Cohen outlines in two substantial chapters, adequate though philosophically less sophisticated than the account given by Dr B.D. Mackenzie in his recent book on *Behaviourism and the Limits of Scientific Method* (Routledge and Kegan Paul: London, 1977). It may be briefly summarised as follows. First, Watson had already proclaimed that psychology is (or should be) "a purely experimental branch of natural science whose theoretical goal is the prediction and control ofhuman behaviour". There seems little doubt that Lashley was fully in accord with this view. Secondly, both men insisted that introspection, for so long viewed as indispensable to the analysis of mind, has no place in behaviourist psychology; nor is the value of its data dependent "on the readiness with which they lend themselves to interpretation in terms of consciousness". Lashley later devoted two important papers to justifying this contention. Thirdly, behaviourism was in keeping with traditional Darwinism in so far as it recognised no sharp distinction between the behaviour of animals and that of man. At the same time, it must be borne in mind that, despite the preoccupation with animal behaviour which seemed almost to obsess the behaviourists, it was the understanding of human behaviour which Watson came increasingly to regard as the primary objective of psychological science.

In his seven years at Johns Hopkins, Watson was somewhat less active in personal research but successful in building up a Department of high standing in its field. He was particularly interested in developing detailed observational study of the development of behaviour in young children, particularly their emotional reactions, in connection with which he drew inspiration not only from Pavlov but, more surprisingly, from Freud, whose observations on infantile sexuality par-

Watson at Johns Hopkins, testing an infant's reflexes

Photos: Johns Hopkins University Archives

ticularly impressed him. Much of this work was carried out by his graduate students, one of whom was Rosalie Rayner, later his second wife, and some of their work was reported in *Psychology from the Standpoint of a Behaviourist* (1919), by far Watson's best book. It is odd that an important paper on conditioned emotional reactions in children, written in collaboration with Rayner, is not cited in Watson' bibliography as given in the present book.

In 1920, Watson featured in a divorce case which brought him considerable notoriety and entailed his enforced resignation from his Professorship. The whole sorry story and its attendant circumstances are fully described by Dr Cohen and it is of some interest to note that E.B. Titchener, a conservative Englishman who for many years represented the Wundtian tradition in America and who had no use whatsoever for behaviourism, was one of the very few professional colleagues who stood by Watson after his fall from grace. In spite of Titchener's support, however, Watson was never again offered a University post and resigned himself to a career in advertising, in which, however, he seems to have been strikingly successful. He also wrote a number of popular articles concerned with child upbringing and education, some of which won the approval of Bertrand Russell, who had himself experienced academic rejection at first hand and was no stranger to the devastating smugness of many American academic institutions some fifty years ago.

The only serious scientific work which continued to engage Watson after his resignation from Johns Hopkins was his observational work on young children. Although much of this was undertaken by a devoted co-worker, Mary Cover Jones, the ideas were undoubtedly Watson's and the work resulted in several interesting, if desultory, publications. Today, this work is of interest largely as the forerunner of what has come to be known as behaviour therapy, which has become a major industry in clinical psychology. Watson, however, did no more than adumbrate the theory and methods of behaviour therapy; its systematic development is the work of others more recent.

Had Watson remained active in psychology, one may hazard the guess that behaviourism would have run a very different, and perhaps more fertile, course. In particular, the obsession with learning theory which infected American psychology in the 1940s and 1950s, and in attenuated form is still with us today, might have proved altogether less dispiriting. On the other hand, the neurological element in Watson's thinking, later developed with such distinction by Karl Lashley, might well have taken earlier and firmer root in American psychology. The advent of behaviour therapy, too, might well have taken place sooner, and been less disfigured by empty 'scientism' and doctrinaire rejection of Freud and all his works. Finally, a tradition of research on human development might have grown up in America well before Piaget became the monolithic institution that he is today. As a "purely American production", Watson's behaviourism had a genuine feel for biology and a healthy freshness and enterprise in tackling the problems of experiment in the sphere of mind. Like many other American products, unfortunately, Watsonian behaviourism failed to survive the Depression. □

O.L. Zangwill is Professor of Experimental Psychology in the University of Cambridge, UK.

Skinnerian behaviour

Stuart Sutherland

The Shaping of a Behaviorist. By B. F. Skinner. Pp. 373. (Alfred A. Knopf; New York, 1979.) $12.95.

To the general public B. F. Skinner is perhaps the best known experimental psychologist. He has attained fame by repeatedly asseverating the principle that all behaviour is governed by reinforcement, and by his sinister but well intentioned suggestion that we should engineer everyone's environment from birth to produce desirable behaviour. The second volume of his autobiography, *The Shaping of a Behaviorist,* describes his life between the ages of 26, when he entered graduate school at Harvard, and 45, when he became a Harvard professor. The title is misleading: the book in fact fails to reveal the schedule of reinforcement that deflected the young Skinner from his interest in English literature and turned him into a Behaviourist so extreme that he denied the existence of mental events. Unfortunately he abides by his own precepts, and gives no hint either of his own feelings and emotions or of those which actuated the numerous colleagues, acquaintances and girl friends who appear in these pages. In consequence, the book resembles a set of scientific protocols in which events are meticulously recorded but all speculation about cause and effect is avoided.

Skinner's professional success is in part due to his capacity for disciplining himself and for making the utmost use of his talents. He seems rarely to have had an idea that did not eventually appear in print: his book on verbal behaviour was planned ten years before it was written. His substitute for prayer was to write stern notes to himself: when he was thirty he prepared a document entitled "Plan of the Campaign for the Years 30—60" which ends with the frank acknowledgement "Plan for the Years 60—(?). These are beyond my present control". To explain how such elaborate exercises in planned self-control are learned would be a nice challenge to his own theory.

The period of his life described was by no means an easy one. It is true that he gained a prestigious Junior Fellowship at Harvard, but finding academic positions in the Depression was difficult and he was forced to exile himself to the University of Minnesota and subsequently to Indiana before returning triumphantly as a full professor to Harvard in 1948. During the War he attempted to train pigeons to guide a missile on to its target, but the idea was never taken up by the military authorities. He brought his second daughter up in a specially designed crib, but his attempts to market the "Heir Conditioner" were unsuccessful. Moreover, much of his early work on animal learning met with little acclaim and was overshadowed by the grandiose theorising of Hull and Tolman.

From an early age Skinner set himself against theorising: he was interested only in finding some behaviour that would vary in a quantitative way with changes in the controlling factors. For him the discovery of such a lawful relationship was enough, and he showed little concern over the novelty or importance of his findings: indeed in the absence of a theory, there can be no criteria for what is an important finding.

Nor did Skinner open up any

B. F. Skinner

Photo: Christopher S. Johnson

fundamentally new areas of investigation, with the exception of the effects of different schedules of reinforcement: even this work led less to the discovery of new principles than to the elaboration of his basic postulate of reinforcement. If a rat is not rewarded for pressing a bar until one minute has elapsed since the last reward, it learns to press infrequently for a time after reward is delivered and more frequently towards the end of the one minute interval. Skinner explained this result by pointing out that only bar presses made after one minute has elapsed will be reinforced, and hence the animal will come to give more responses after that interval and fewer immediately after reward; the nature of the timing processes that underlie such behaviour was of no interest to him.

Within the limits that Skinner imposed on his own thinking, he often displayed considerable ingenuity. He was amongst the first to distinguish clearly between the classically conditioned Pavlovian reflex and 'operant' responses in which reward is made contingent on the occurrence of the response. He also showed great skill in the design of apparatus for the automatic recording of behaviour, though at the expense of restricting the behaviour recorded. He does not make it altogether clear whether the famous Skinner box was an attempt to make the recording of behaviour more objective or whether it was a device to enable him to carry out more experiments with less effort.

It is interesting to speculate how Skinner's impoverished view of the task of psychology came to attract so wide a following. His insistence on quantitative results may have appealed to those who wanted psychology to attain the respectability of a science; his doctrine of the malleability of man fitted the prevailing ethos of self-improvement in America; his insistence that what was inside the organism was the province of physiology, whereas psychology should concentrate on the whole organism gave psychology status as an independent discipline; and his concentration on the role of reinforcement to the exclusion of all other problems obviated the difficulty of thinking about such complicated questions as how the organism stores or retrieves information.

Psychology is now a very different subject and the study of mental processes is once more fashionable. The next volume of Professor Skinner's autobiography will doubtless record how his fame amongst the general populace spread at the time his influence on the academic community was waning. One can only hope that he will relax his professional austerity sufficiently to tell us not only what happened but how he felt about it. □

Stuart Sutherland is Professor of Experimental Psychology at the University of Sussex, Brighton, UK.

The Cardinal Sin

Ann M. Clarke
A. D. B. Clarke

Cyril Burt: Psychologist. By L. S. Hearnshaw. Pp. 370. (Hodder and Stoughton: London; Cornell University Press: Ithaca, New York, 1979.) £8.95.

THIS is a book about an eminent psychologist who committed the scientist's cardinal sin, deception and fraud, during a long productive life which brought him nearly all possible distinctions except Fellowship of the Royal Society. He is to be condemned not for the views he espoused, many of which we share albeit in a less extreme form, but for his irregular conduct over many years. On the penultimate page of Sir Cyril Burt's biography the author writes:

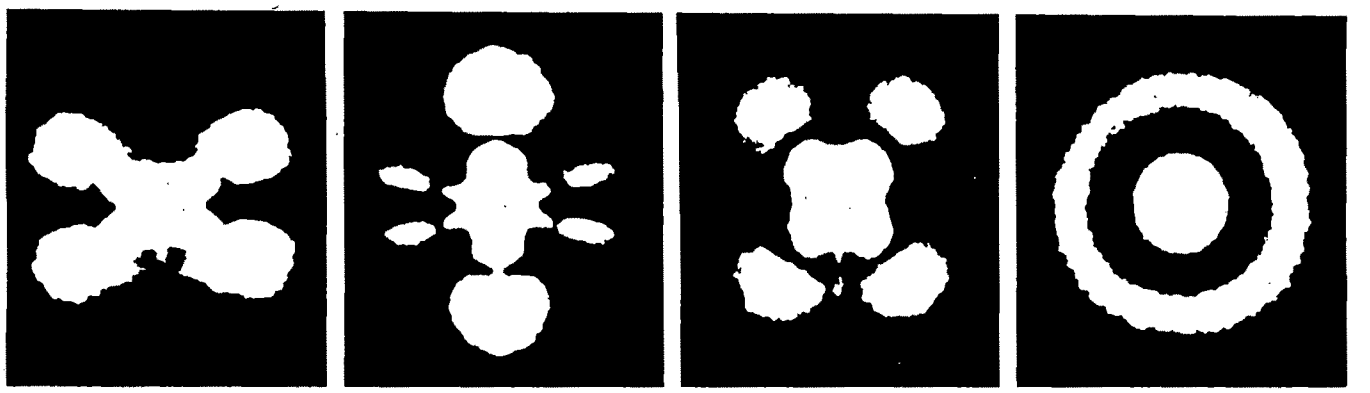
"It would be totally unfair for a final judgement on Burt to focus on his deceptions to the exclusion of all his positive achievements. He was not, perhaps, either by training or temperament a scientist. He was too impatient to reach, and too confident of having reached, firm conclusions which became for him very early in his career, articles of almost religious faith to be defended at all costs. Yet he brought to psychology many conspicuous gifts..."

Be that as it may, his major claim to fame certainly outside his profession, was his work on the heritability of intelligence, and in this connection many distinguished scientists on both sides of the Atlantic accepted his findings on the assumption that the data as reported were sound.

This beautifully written and well researched book records the life and works of an often charming, sometimes generous and kind, always erudite yet unscrupulous man who deserves a high place in science's rogues' gallery. In 1905, while reading classics at Oxford, he recorded in his diary "My purpose in life concerns primarily myself. It is to produce one perfect being for the universe", and went on to list the necessary virtues. Regrettably he failed to follow his own precepts. Shortly after graduation he was appointed assistant to Charles Sherrington at Liverpool. He remained there five years, commencing his research career and gathering his first data to prove that what he called "general cognitive ability" was innate. As Professor Hearnshaw notes:

"inadequate reporting and incautious conclusions mark this first incursion of Burt into the genetic field. We have here right at the beginning of his career, the seeds of later troubles."

In 1912, with a reputation already firmly established and on the recommendation of Spearman and Sherrington, Burt was appointed psychologist to the London County Council on a half-time basis. Spearman had written:



"I can add that he is considered by most experts to be the most brilliant and promising of the younger generation of psychologists in the British Isles...".

Burt seems to have worked indefatigably to collect data on abilities and attainments of London school children and on the development of mental and scholastic tests for their assessment.

Appointed in 1922 to a half-time post in the National Institute of Industrial Psychology to organise its vocational department, Burt remained there for two years and among other things taught some of his colleagues to 'estimate' the IQs of adults without actually testing them! In 1924 he was elected to a part-time Professorship of Educational Psychology in the then London Day Training College, later to become the Institute of Education.

In 1931, aged 48, Burt succeeded Charles Spearman in the Chair of Psychology at University College, London. During the next thirty years, factor analysis became his major interest. He began to make claims to priority as first user of this method, but these were at once retracted when Spearman challenged him. With the latter's death in 1945, however, Burt began to rewrite the history of these statistical techniques, dethroning Spearman as their originator. In a number of publications, especially from 1947 onwards, he began "to make claims about his own early work which were demonstrably contrary to the truth" (page 173). Far from having followed Spearman's lead, he now alleged that he had pursued a different route, and that he was in disagreement with Spearman from the start, a view belied by extant correspondence between them. Later "the claims got more and more extravagant". As Hearnshaw notes, there is a pathology here, of which we could ourselves offer further examples.

Burt retired from his Chair at University College in 1950, after unsuccessfully trying to influence the appointment of his successor. His subsequent attempts at interfering with the running of the Department ultimately led to his exclusion from the College on the decision of the Provost who had earlier warned the new incumbent against allowing Burt any access. The twenty-one years of retirement witnessed a surge of publications on a major theme, the importance of genetic factors in human ability and the unimportance of environment. His most influential papers were all published in journals with which he had a close personal connection. As founder and editor of *The British Journal of Statistical Psychology* from 1947 to 1963 and later as assistant editor, he used it as a frequent outlet. His gross abuse of editorial powers was to some extent known at the time, at least to people like

THE SINKING ARK A New Look at the Problem of Disappearing Species

Norman Myers

The world's stock of species is one of our most valuable raw materials. Properly conserved, the genetic starting-point materials of increasing numbers of foods, drugs and industrial products can be exploited indefinitely – once destroyed, they are irreplaceable. It isn't enough to identify individual endangered species. The resource at risk is diversity in the gene pool, in the "minor" species of plant and insect life constituting over 90% of the total stock. Dr. Myers shows how the adjustment of international resource relationships via the New International Economic Order could defeat the economic pressures towards broadscale species extinction, and explains how environmentalist pressure-groups must now turn to the nuts-and-bolts design of the appropriate institutional fixes.

Proceedings of the International Symposium, Wenner-Gren Center, Stockholm, 1978

Editors: **C Von Euler & H Lagercrantz,** *Karolinska Institute, Sweden*

Featuring contributions from over forty leading physiologists and clinical scientists from Europe and America, this volume displays a smoothly integrated exchange of ideas between 'basic' and 'clinical' research workers. A particularly interesting feature is the section devoted to developmental aspects and perinatal problems.

MUSCULAR EXERCISE IN CHRONIC LUNG DISEASE

Proceedings of a Meeting on Factors Limiting Exercise, Nancy, 1978

Editors: **M. Gimenez & C. Saunier** *INSERM, France*

A considerable amount of research by physiologists has been devoted to the benefits of exercise for those with respiratory insufficiencies. These exercise tests have already been sufficiently proved to be necessary in judging respiratory deficit.
The 39 contributions in this volume examine factors limiting the possibilities of exercise in patients with chronic respiratory insufficiencies.

The Zoology of

THE VOYAGE OF H.M.S. BEAGLE

CHARLES DARWIN

Available for the first time — a 3 volume facsimile reprint of this important and rare work

SPECIFICATIONS
Size: 318mm x 250mm (12½" x 9¾")
Extent: 1008 pages (3 volumes)
Plates: 165 (83 B/W, 82 colour)
Binding: ¼ bound in leather with quality linen
Edition strictly limited to 750 copies
Price £309.00

Over 500 species of fossil mammals, mammals, birds, fish and reptiles are described and illustrated by the best authorities of the time, supervised and edited by Charles Darwin.

Among the numerous illustrations are 50 colourplates of birds by John Gould.

DILLON'S UNIVERSITY BOOKSHOP

1 MALET STREET, LONDON WC1A 7JB Tel. 01-636 1577 (16 lines)

One of the world's leading booksellers, Dillon's invites you to choose from over 150,000 technical, academic and general titles covering all subject areas.

This large and varied stock enables us to provide a comprehensive service to both personal and Mail Order customers. We will post books to individuals and institutions in the United Kingdom and overseas, or arrange subscriptions to newspapers and journals. We also offer credit facilities, and a quotation service for large and small orders alike.

For further information, write to the Mail Order Manager with details of your requirements and subjects of interest.

A Pentos Company

ourselves around London. Apart from publishing 63 articles under his own name, he frequently altered authors' texts without permission, often misrepresenting their intention and adding favourable references to his own work. In addition "Of the more than forty 'persons' who contributed reviews, notes and letters... well over half are unidentifiable, and judging from the style and content were pseudonyms for Burt" (page 245).

Burt could also be kind and generous, as he usually was to us; Hearnshaw records many tributes from former colleagues and students. He could equally be autocratic and vicious towards, for example, a close colleague to whom he wrote a barrage of memoranda and letters pouring scorn on his research. All this to someone to whom staff and students were deeply attached, and upon whose devoted labours the functioning of the Department largely depended (page 143).

With his undoubtedly brilliant mind and wide educational and clinical experience, Burt became from the 1920s and onwards much in demand for evidence and advice on a variety of practical problems. Hearnshaw suggests that he influenced the developing pattern of English education, as well as contributing to policy in such fields as mental deficiency, delinquency and War Office selection procedures.

So far as any scientific theory is concerned it matters little whether Burt's claim to possess a vast store of data on the intellectual status of relatives was true; their poor quality and many anomalies in reporting were outlined in three independent publications in 1974. However, when in 1976 Dr Gillie of *The Sunday Times*, with our support, charged Burt with fraud there were strong protests. Such charges, particularly in connection with his sample of monozygotic twins reared apart (unique both in size and in extent of environmental differences, mainly reported in the 1950s and 60s) could, however, be made with impunity once Dr Gillie's fairly extensive enquiries had established that Burt's alleged collaborators, Margaret Howard and J. Conway, existed in no relevant records, nor were they known to colleagues at University College nor to his secretary/housekeeper. Space precludes a detailed account of Hearnshaw's later careful researches in connection with the charges; in his endeavour to be both brief and balanced, he has omitted many of Burt's conflicting stories to interested scholars during the last few years of his life, confining himself to a small but adequate sample.

Hearnshaw presents overwhelming evidence

"that neither Burt nor any of his alleged assistants carried out any field work after 1955, and it is probable that all his data, such as it was, had been collected prior to his retirement in 1950, most of it, indeed, prior to the Second World War. Burt certainly added no data himself after leaving University College, and there is no evidence of any contact or communication with any assistants" (page 239).

Moreover, he did not have, as he frequently alleged, material stored there.

The biographer acknowledges the possibility that the data simply did not exist, but writes:

"Assuming that the data were collected in the first instance, and there seems reasonable grounds for thinking that at least some was, what happened to it? The answer almost certainly, is that the bulk of it was destroyed during the war."

Cyril Burt

The evidence in support of this conclusion is less than convincing, and includes a letter from Burt to University College written from Aberystwyth in February 1941, requesting permission to store

"files of case-histories of defective, neurotic and delinquent children, rather large collections of children's drawings, compositions etc. systematically gathered while I still had access to London schools..." (page 248).

There is no mention of twin data nor any other material relating to intelligence test results for relatives. Whatever the truth of the matter, one thing is certain: as we pointed out over two years ago, the unknown Miss Conway did not double the size of the separated monozygotic twin sample, between 1955 and 1958, as 'she' and Burt claimed, nor were any further cases examined thereafter. Furthermore, it seems safe to assume that whatever data Burt may once have collected on various kinship correlations these, as M. McAskie (Hull) and more recently D. Dorfman (Iowa) have contended, were not available to him at the time of writing his seminal papers.

It is also clearly established that information on declining educational standards said to have been compiled by another unknown lady, Miss M. G. O'Connor, which included surveys carried out in 1955 and 1965 (discussed in the 1969 *Black Paper* and in the *Irish Journal of Education*) "were at least in part fabricated" (page 259).

Hearnshaw takes issue with those who like ourselves would dismiss Burt altogether on this evidence, pointing to the esteem with which he was held almost universally in the early stages of his career, and by many up to the time of his death. Among these were two of our former teachers, who we believe would never have expressed their approval had they known what is revealed in this book. The author alludes to Burt's use of short cuts, yet maintains that his contribution to applied psychology was important and must be taken into account in the final evaluation. We have reservations about this conclusion. For example, we have a little known report, published in 1924, in which he states that by means chiefly of psychological and educational tests, he had made an intensive study of backward children. "During the four weeks covered by my visit to Birmingham I personally tested 562 children. This was at an average rate of rather over ten minutes to every child". The psychological examination which he personally undertook used "chiefly the Binet-Simon tests of intelligence revised for English children". From our own extensive experience of testing such children we find this a disturbing example of taking short cuts, particularly as Burt was subsequently regarded as an authority on *The Subnormal Mind*. Later advances in this applied field in fact owed virtually nothing to him.

We cannot recommend too strongly this scholarly yet easily read biography. For this reason we refrain from comment on the well researched and fascinating suggestions concerning Burt's pathological personality and why he behaved as he did. This must have been a difficult book to write, partly because Burt was in Professor Cohen's words "a polymath of Renaissance dimensions"; partly because it was originally commissioned by Burt's sister who, after the public charges made against her brother, remained "convinced of Cyril's integrity"; and partly because of the heavy responsibility for sifting the evidence and arriving at an acceptable account of the life and works of an eminent psychologist who inspired devotion in some and distrust in others.

Two disturbing questions remain. First, why were Burt's deceptions unrecognised for so long? Second, is this case unique in our time? □

Organic Stereochemistry

Henri Kagan

In this concise treatment of organic stereochemistry, the author makes few assumptions about the student's previous knowledge, but eventually reaches a level of understanding suitable for most graduate students.
Stereochemistry constitutes an area of chemistry which, if not a distinct science, is an area which can be conveniently treated as a unit. The subject developed within the discipline of organic chemistry and is permeated by the ideas of organic chemistry. However, with the development of effective methods of studying chemical compounds in the solid state, inorganic chemistry has acquired a distinct and comparably large stereochemistry of its own which is better treated separately. Hence it has been necessary to give this text the title 'organic' stereochemistry.

Electronic Logic Circuits

J. R. Gibson

The growing use of electronic logic circuits is leading to the introduction of courses at an early stage of degrees in electrical engineering. This text places its emphasis on applications of logic circuits and on design techniques which lead to reliable circuits. This treatment will also be useful to qualified engineers who have not specialised in the subject but who occasionally wish to incorporate simple logic circuits into a system.

Paper £3.95

Elementary General Relativity

C. Clarke

General relativity is becoming popular both in undergraduate mathematics courses and as a subject for research. Although there are many texts concerned with the less advanced concepts of special relativity, this is the first dedicated to providing a suitable background in general relativity for students and researchers.

Phenomenon of human culture

Edmund Leach

Cultural Materialism: The Struggle for a Science of Culture. By Marvin Harris. Pp.381. (Random House: New York, 1979.) $15.

THIS is the sixth substantial book that Harris has published since the beginning of 1964. It would be unfair to say that to have read one is to have read them all but certainly there is a great deal of repetition. In the present case the author himself points out (page 77, footnote) that chapter 4, "The Scope of Cultural Materialist Theories", is a partial synopsis of his textbook *Culture, People, Nature: An Introduction to General Anthropology* (1971). Other familiar arguments derive from *The Rise of Anthropological Theory* (1968), *Cows, Pigs, Wars and Witches: The Riddles of Culture* (1974) and *Cannibals and Kings: The Origins of Culture* (1977), but have also appeared in various shorter productions. Second and third time round Harris has not modified any of his positions in response to the chorus of criticism from professional colleagues. Instead he stridently proclaims that he has been misrepresented and then counter-attacks in like measure.

The book is in two parts. Part I, "Cultural Materialism as a Research Strategy", summarises Harris' position and only just falls short of claiming that Harris himself will prove to be as significant for the history of anthropology as Darwin has been for the history of zoology. Part II, "The Alternatives", contains chapters labelled "Sociobiology and Biological Reductionism", "Dialectical Materialism", "Structuralism", "Structural Marxism", "Psychological and Cognitive Idealism", "Eclecticism", and "Obscurantism". Collectively these " 'isms" are all embracing and there are few contemporary anglophone or francophone social or cultural anthropologists of any reputation, either distinguished or undistinguished, who do not get an adverse mention somewhere. Indeed, Harris manages to convey the impression that all current forms of anthropological theorising other than his own are completely worthless. For anyone who already knows the facts of the matter most of this shadow-boxing is extremely boring but Marshall Sahlins, whose long review of *Cannibals and Kings* in the *New York Review of Books* provokes repeated anathemas, must be quite delighted to have got such a rise out of his victim.

It is useless for a reviewer to comment in any detail upon these exercises in academic abuse. Harris conducts a one-sided shouting match against named but inaudible opponents, but if one takes the trouble to discover what these opponents actually said it nearly always turns out either that the other side has much the stronger case or else that Harris' sarcasm completely misses the point. No doubt there are many of Harris' undergraduate readers who will only be too delighted to learn from a senior Professor that they need not bother to try to understand the mathematical, transformational intricasies of Lévi-Straussian structuralism because it is all a lot of nonsense anyway; but, to the initiated, all that Harris manages to demonstrate in this particular chapter is that he himself has completely misunderstood Lévi-Strauss.

The attack on the structural marxists has a more personal twist. In the first place Harris wants to persuade his readers that Cultural Materialism is a sort of improved Marxism with the Hegelian dialectic left out! But besides that, in attacking the 'idealism' of the structural marxists, he is also trying to get his own back on former colleague and pupil Marshall Sahlins and Jonathan Friedman, both of whom have treated Harris' earlier publications with mocking disrespect. But here again most readers are likely to feel that Harris gets much the worst of the argument. And so it goes on. No doubt some of the targets for Harris' boomerangs deserve to be hit, but his scorn is so indiscriminate that the only impression that survives is astonishment at Harris' personal vanity and lack of scholarly judgement.

So what is at issue? In part it is a very old argument indeed. Harris' favourite jargon which opposes 'emic' and 'etic' approaches to culture is only a rehash of the mediaeval disputations over the existence or non-existence of universals which divided the realists from the nominalists. Here Harris' support for an 'etic' position entails a realist universalist doctrine, which is curious in view of his otherwise passionate antipathy to the metaphysics of idealism in all its forms! In other respects Harris' creed is the unsophisticated materialism of the mid-nineteenth century, the standard definition of which is "the view that all facts (including facts about men's minds and wills and the course of human history) are causally dependent upon physical processes, or even reducable to them". Harris is obsessed with the idea that the anthropologist's essential task is to elucidate the causes which have produced the phenomena of human culture as they can now be observed and as they have occurred in history. He believes further that these causal sequences have been simple rather than complex and that the underlying causal principles can be discovered by *a priori* reasoning concerning energy inputs

and outputs without any reference to the fine details of historical or archaeological evidence. In Harris' view virtually all the diverse peculiarities of human culture can be "explained" by taking close note of such "empirical" factors as ecology, protein resources, and population density; but, above all, a universally valid economic law of nature will ensure that historical development will proceed in such a way that, in the long run, a minimax principle will govern the balance of cultural costs against cultural benefits. Harris seems to regard this principle as a sort of anthropologist's equivalent to the second law of thermodynamics; but, as Sahlins has pointed out, it is simply a value judgement among other value judgements and closely akin to the profit motive which so many of Harris' neighbours on Manhattan Island also consider to be a law of nature. Just how far Darwin was right in this regard on the issue of biological evolution is still an open question, but Harris' support of Adam Smith's earlier contention that, in free-for-all economic competition, efficiency will always win out against both politics and morality is mere mysticism.

Harris' professional colleagues disagree with him on a great variety of issues. I can mention only a few. Most of us would hold that in the absence of detailed historical records it is just as difficult to reconstruct the past as to predict the future, so that anthropologists will be well advised to devote their energies elsewhere. Harris' exercises in conjectural history are no doubt very satisfactory for that wide class of general reader whose members want to believe that everything is very orderly and simple and that everything that has ever happened in history is quite easily understood if only we apply the most simplistic principles of common sense; but it does not seem likely that there can be many members of the scholarly professions who would take that line.

Another major objection that has been raised against Harris' work is his irresponsible misuse of the limited historical evidence at his disposal. Any ordinary non-anthropological reader of Harris' books must get the impression that it is an unambiguous, fully established, historical fact that at the time of the Spanish conquest of Mexico the ordinary diet of ordinary Aztecs was desperately deficient in animal protein. Harris in fact claims that it is this dietetic deficiency which provides a "scientific" explanation for the uniquely elaborated institution of cannibalistic human sacrifice among the Aztec. But in fact there is no clear evidence that human sacrifice and cannibalism were closely associated among the Aztec or that the Aztec were ordinarily any more deficient in animal protein than most human populations at most periods of human history.

Complaints of this sort can be raised against almost the whole of Part I of Harris' book. He exhibits *Cultural Materialism* as a crudely simplified theory of law-bound social evolution which most professional anthropologists are likely to find even less convincing than that offered by Morgan in *Ancient Society* (1878). The theory is not derived from any ethnographic evidence; ethnography is only brought in as illustration, but often in such a slap-dash way as to be totally misleading. For example, around page 104, Harris is discussing his theory of the origin of the state, which is heavily dependent upon the theory put forward by Wittfogel in 1957 concerning the significance of large scale irrigation works for the formation of centralised forms of administration. "It seems likely", writes Harris, "that there was a causal relationship between the size and importance of irrigation systems and the degree of centralisation of political power". He then illustrates this thesis by the examples which Wittfogel himself used: Nile Valley, Yellow River, and so on. But how likely is likely? How large is large? Harris never tells his readers that the earliest large scale irrigation system so far identified by the archaeologists is in Highland New Guinea, a discovery which runs entirely counter to the whole of Harris' *a priori* argument!

Nor is it only on technical issues of anthropology and archaeology that Harris seems at times to be almost wilfully careless. Harris would like his readers to believe that he is well grounded in the philosophy of science. At pages 13-14 we are given a one paragraph summary of logical positivism which is described simply as "a movement which arose in Vienna" (no names; no dates). Two pages later we are told that the verification principle of the logical positivists has been "severely attacked in recent years" under the influence of "the English philosopher Karl Popper". Needless to say *Logik der Forschung* (1935) is cited only in the English edition of 1959. For a scholar who makes such a fuss about the importance of origins and causal sequences this is surely a very astonishing way of presenting the complicated history of the Vienna Circle of which Popper himself was, almost from the start, a very influential, though peripheral, member.

This book will not add to Harris' professional reputation but, regrettably, the cheap sarcasm which Harris directs against the serious arguments of his colleagues often makes a good read. Consequently it may well reinforce the illusion created by Harris' other books that social/cultural anthropology is not a serious academic pursuit at all and that explanation in these fields exists only at the level of Kipling's *Just So Stories*. Some anthropological writing is like that, but not all. □

Sir Edmund Leach is Professor Emeritus of Social Anthropology in the University of Cambridge, UK.

For publication in December:

Fundamentals of Mycology
Second edition
J. H. Burnett
A revised and updated edition of an established textbook which was the first to depart from the traditional taxonomic treatment of the fungi and deal with the general features of the group as a whole.

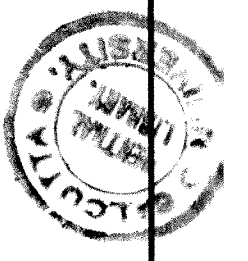
Reviews of the first edition:
'This scholarly book is almost breath-takingly comprehensive . . . Such is its vision and scope that few mycologists will fail to profit from reading it, whatever their special areas of interest.' — *Transactions of the British Mycological Society.*

'A remarkable synthesis of ideas and data in what is now a vast subject area . . . the book presents a clear coherent picture of our current state of knowledge.' — *Journal of Biological Education.*

'A unique and masterly book that everyone who wants to know about or work with fungi should possess.' — *The New Phytologist.*

Paper £16

Social Behaviour in Primates
Neil Chalmers
Contemporary Biology Series
This area of study has expanded rapidly in recent years and Dr Chalmers provides a conceptual framework within which he organises the available facts. He discusses three different aspects of primate behaviour, namely infant development, sexual behaviour and dominance, and concludes by examining critically adaptive explanations of primate social behaviour and comparisons of human and non-human primates.



Paper £6.50

Field and Laboratory Exercises in Ecology
S. D. Wrattan and G. L. A. Fry
This book represents the first practical integration of quantitative exercises in plant and animal ecology. Fifty-six exercises, grouped in pairs of complementary field and laboratory experiments and arranged round five major ecological themes, are worked through in full detail and a further 150 variations, some suitable for long term projects, are offered.

Gaia and creative evolution

René Dubos

Gaia: A New Look at Life on Earth. By J.E. Lovelock. (Oxford University Press: Oxford and New York, 1979.) £4.95.

I HAVE always disliked the expression "Spaceship Earth" to designate our planet and I believe that it has led to faulty thinking about environmental problems. The word spaceship calls to mind a mechanical structure carrying a limited supply of fuel for a defined trip and with no possibility of significant change in design. The Earth, in contrast, has many attributes of a living evolving organism. It constantly converts solar energy into innumerable organic products and increases in biological complexity as it travels through space. I was therefore much interested when Jim Lovelock suggested in *New Scientist* in 1975 that the surface of the Earth behaves as a highly integrated organism capable of controlling its own composition and its environment. He used the name of the Greek Earth goddess Gaia to symbolise this complex biological behaviour of the Earth. Lovelock has now developed the Gaia hypothesis in a book that I have read with immense pleasure. I shall first briefly summarise its factual contents, then formulate a few questions in the hope that they will lead to a further development of the hypothesis.

It is not the first time that the Earth has been regarded as a living organism. In a book entitled *The Land Problem,* Otis T. Mason, one of the early American environmentalists, wrote in 1892, "Whatever our theory of its origin, the earth may be discussed as a living, thinking being . . .". The Gaia hypothesis is more concrete and can best be formulated in Lovelock's own words: "The physical and chemical condition of the surface of the Earth, of the atmosphere and of the oceans has been and is actively made fit and comfortable by the presence of life itself. This is in contrast to the conventional wisdom which held that life adapted to the planetary conditions as it and they evolved their separate ways.".

The Gaia concept has its origin in the fact that the chemical composition of our atmosphere is profoundly different from what it would be if it were determined only by lifeless physicochemical forces. In an Earth without life, purely physicochemical phenomena would produce for example an atmosphere containing approximately 98% carbon dioxide with very little if any nitrogen, whereas the corresponding figures for our atmosphere are approximately 0.03%, 79% and 21%. Lovelock presents numerous other examples of such profound departures from chemical equilibrium and postulates the existence of a global force which is able to bring about and keep fairly constant a highly improbable distribution of molecules. He believes that this hypothetical global force consists of the countless forms of life which create and maintain states of disequilibrium through cybernetic systems. Some of these are described in the book. As I do not have the competence to evaluate the validity of Lovelock's physicochemical arguments, I shall restate the problems he discusses in biological terms with which I am more familiar.

The fitness of an organism to its environment is, of course, an essential condition of its biological success and even survival. All living things seem to be endowed with a multiplicity of mechanisms that enable them to achieve fitness by undergoing adaptive changes in response to those of the environment — genetic changes that occur during the evolution of the species, physiological and anatomical changes that occur during the existence of each particular organism. In higher species and especially in humankind, these biological mechanisms are supplemented by adaptive social forces. Early in the present century, however, the Harvard physiologist L.J. Henderson pointed out that there was more to fitness than the adaptive potentialities of living things. As he claimed in his famous essay "The Fitness of the Environment," the achievement of fitness depends not only on adaptive mechanisms but also on the fortunate fact that the terrestrial environment has certain physicochemical attributes which happen to be just right for life. But this theory now seems essentially meaningless for the following reasons.

Many present forms of life would certainly be annihilated if the surface of the Earth were very different from what it is now. They could not adapt rapidly enough if the salinity, the acidity, the relative proportions of gases, minerals and organic substances — or any of the other physicochemical characteristics of the Earth — were to deviate far from their present values for any length of time. In other words, the present environment does indeed exhibit fitness for the present forms of life but — and this is what Henderson had overlooked — it would have been unsuited to those of the distant past. An atmosphere with 21% oxygen, for example, would have been extremely toxic for the earliest forms of life.

During the past 3.5×10^9 years, the global environment has progressively changed, probably as a consequence of the activities of living things, and living things also have undergone corresponding changes through a feedback process. The Gaia system postulated by Lovelock therefore seems be a result of co-evolution. Instead of listing the chemical examples of this creative process discussed by Lovelock, I shall quote a picturesque phrase taken from one of his recent articles: "The air we breathe can be thought of as like the fur of a cat and the shell of a snail, not living but made by living cells so as to protect them against an unfavorable environment.".

A few years ago, theoretical discussions were instigated by NASA to consider the possibility of making the planet Mars suitable for human life — which meant providing water, oxygen, moderate temperatures, protection from ultraviolet radiation, and so on. The general conclusion was that Mars could be made habitable only through the progressive introduction of living species capable of creating, over an immense period of time, more and more complex ecosystems similar to the ones which have evolved on Earth during more than 3×10^9 years. This analysis has helped us recognise the profound and innumerable changes that life had to bring about on the surface of primitive Earth to create, for present living things, the fitness of the terrestrial environment that L.J. Henderson had taken as the normal state of affairs.

According to the Gaia hypothesis, the Earth's biosphere, atmosphere, oceans and soil constitute a feedback or cybernetic system which seeks an optimal physical and chemical environment for life on this planet. At any given time, this system results in a relative constancy both in the composition of the environment and in the characteristics of living things. Repeatedly throughout his book, Lovelock refers to this equilibrium as "homeostasis" — a word invented by the Harvard physiologist, Walter B. Cannon, to denote the remarkable state of constancy in which living things can maintain themselves despite changes in their environment.

The word homeostasis, however, does not do full justice to the Gaia concept, which implies in addition that living things have profoundly transformed the surface of the Earth while themselves undergoing continuous changes, in a co-evolutionary process. Practically all the examples that Lovelock discusses refer, in fact, to creative evolution rather than to homeostatic reactions. For example, the accumulation of oxygen in the air which became significant 2×10^9 years ago (as a result of biological photosynthetic activities), probably destroyed many forms of life for which this gas was poisonous. In Lovelock's words, however, "Ingenuity triumphed and the danger was overcome, not in the human way by restoring the old order, but in the flexible Gaian way by adapting to change and converting a murderous intruder into a powerful friend.". Cybernetic mechanisms progressively brought about the emergence of biological species capable of living in the presence of oxygen and of using it for the production of energy. In this case, as in

Plasma Proteins

edited by **B. Blombäck,** *Institution for Coagulation Research, Karolinska Institute, Stockholm*
and **L.A. Hanson,** *Department of Immunology, Institution for Medical Microbiology, University of Gothenburg, Sweden*
Co-ordinating editor: **H. Winberg,** *AB KABA, Stockholm, Sweden*

This book provides a survey of the developments in the field of the chemistry of the plasma proteins. The biochemistry, physiology and clinical aspects of the more important proteins are discussed in special chapters.

October 1979 — 420 pages
0471 99730 7 — $62.00/£22.50

Progress in Resource Management and Environmental Planning Vol. 1

edited by **T. O'Riordan,** *University of East Anglia School of Environmental Sciences,*
and **R. d'Arge,** *Department of Economics, University of Wyoming*

The first is a series of volumes containing detailed reviews of the state of the art in environmental management.
In line with the general aim that each volume will contain a group of chapters dealing with a particular issue, this book includes two chapters concerning population issues, three on aspects of pollution control in the UK and two on methodological developments in environmental planning. (Series: *Progress in Resource Management and Environmental Planning)*

October 1979 — 336 pages
0471 99746 3 — $38.50/£14.00

Natural Resource Economics: Issues, Analysis and Policy

by **C.W. Howe,** *University of Colorado*

A unified exposition of the principles of optimum use of renewable and nonrenewable natural resources, set in the framework of historical natural resource concerns and real resource markets. The author has utilized the most up-to-date theoretical and empirical research results from economics, geology, hydrology, and the environmental sciences.

August 1979 — 380 pages
0471 04527 6 — $22.95/£10.50

Rocks and Rock Minerals

by **R.V. Dietrich,** *Central Michigan University,*
and **B.J. Skinner,** *Yale University*

Provides a guide and reference that explains how rocks occur, their commercial usage, and how to identify them through macroscopic, handspecimen features. The authors give complete coverage of rock-forming minerals, rocks, and man-made rock-like materials, as well as meteorites, impactites, grossans, and others.

October 1979 — 334 pages
0471 02934 3 — $14.00/£6.75

Soil Physical Properties and Crop Production in the Tropics

edited by **R. Lal,** *International Institute of Tropical Agriculture, Ibadan, Nigeria,*
and **D.J. Greenland,** *International Rice Research Institute, Manila, Phillipines*

This book is intended as a reference work on the physical properties and management of soil in the tropics. For such regions, this book is the first of its kind.
Different aspects of the constraints and their management are written by experienced researchers in the individual subject areas. Soil physical properties, such as structure, water transmission, water balance, soil-temperature regime, root growth, and crop performance are discussed in detail. In addition, a review of recent work in physical properties of tropical soils is presented with a critical appraisal of the methodology used.

ELEONORA'S FALCON

Adaptations to Prey and Habitat in a Social Raptor
Hartmut Walter

Named after a fourteenth-century Sardinian princess, Eleonora's falcon is the only European bird to breed in autumn and to feed its brood on birds migrating from Europe to Africa. It breeds in colonies of up to 200 pairs and often hunts in groups. This beautifully illustrated study is the first in-depth view of a social raptor that shows the tense interaction among raptor species, man, and the ecosphere. 59 line drawings, 38 photographs. £18.50

JOURNAL OF ECOLOGICAL AND LIFE CHEMISTRY

Edited by Derek Bryce-Smith and John Mann

CALL FOR PAPERS

The journal brings together research reports in life chemistry, which up till now have been dispersed in specialist journals of limited readership. While coverage is wide, papers are required to focus on distinct elements of chemical interest. High standard, coupled with breadth of interest and implication, imbues the *Journal of Ecological and Life Chemistry* with editorial scope extending beyond narrower specialist boundaries in biochemistry. The journal contains review articles, original papers, and short communications dealing with all aspects of the chemistry of life processes, for example biosynthesis; organic geochemistry; pherome chemistry; inorganic and organic aspects of metabolism, nutrition, and toxicology; chemotherapy *inter alia*.

CALL FOR PAPERS. The editors would welcome for consideration high-quality papers in the field, and will be happy to provide any further information concerning scope etc. Manuscripts and enquiries should be sent to: Professor Bryce-Smith, Department of Chemistry, University of Reading, Whiteknights, Reading RG6 2AD, England.

SUBSCRIPTION RATES 4 issues per vol.
US/Canada $130 Elsewhere £65
Supscriptions should be sent to London office.

most other environmental changes, the Gaian way was not an automatic homeostatic reaction but a creative co-evolutionary response.

It seems worth considering that the Gaian control results in global homeostasis only over a period of time which is short on the evolutionary scale. One figure will suffice to illustrate the magnitude of the terrestrial changes that are continuously caused by life. In their aggregate, all the green plants now fix approximately 840 $\times 10^{12}$ kilowatt hours of solar energy per year in the form of biomass. This is more than 10 times the amount of energy that all of humankind uses annually, even with its most extravagant technologies. Who can doubt that this continuous process of accumulation of organic matter and energy will eventually affect both the surface of the Earth and various forms of life. Furthermore, Lovelock himself points out that the process of change may pick up speed and complexity as a result of human interventions, and he appropriately quotes me in stating that, on a local level, profound co-evolutionary changes have occurred in certain terrestrial environments and in their biological systems during historical times.

In the last chapter of his book, Lovelock has the courage to explore the relevance of the Gaian hypothesis to the effects of human interventions into nature. I wish I had space to explain why I agree with him when he states that environmentalists often shoot at wrong targets because the resiliency of the Earth, considered as an organism, probably makes ecosystems more resistant to pollution than commonly believed. As I cannot discuss these problems here, I shall conclude by expressing my wish that in the next edition of his book, Lovelock emphasises not only the homeostatic aspects of the Gaia hypothesis but also its creative aspects. This would be in the spirit of his statement that the Gaia concept is an alternative to the "depressing picture of our planet as a demented spaceship, forever travelling, driverless and purposeless, around an inner circle of the sun". □

Pollution in perspective

Kenneth Mellanby

A Perspective of Environmental Pollution. By M. W. Holdgate. Pp. 278. (Cambridge University Press; London, New York and Melbourne, 1979.) £15.

SOME ten years ago I was invited by a British publisher to write a book with the title *Pollution in Perspective*. This was to have been a 'popular' book in which I would try to distinguish between real, damaging pollution and trivial environmental contamination which, though harmless, nevertheless caused so much public concern. Being an idle fellow I procrastinated, and my text is still mainly in my imagination. Therefore, when I saw Dr Martin Holdgate's new book, with so similar a title, my emotions were mixed. On the one hand I felt guilt for not having completed my own book on such an obviously important subject, and on the other hand I experienced relief that someone else had done the job so competently.

For there can be no doubt that Dr Holdgate has produced an excellent book. Although he modestly denies having given his subject complete coverage, I cannot find any significant gaps. All major topics in the field of pollution are dealt with clearly, scientifically and with a full understanding of the facts, where these are easily available, and also the lacunae in our knowledge are always mentioned.

The book starts by placing pollution in its ecological context, and then goes on to define pollution and classify pollutants. A very important chapter is "The significance of pathways" which deals with the way substances are dispersed in the air, in fresh water and in the sea. The significance, sometimes overestimated, of the transmission of toxic substances through food chains is assessed. The great value of the book is that it constantly relates the concentrations of specific pollutants in the environment to the real effects on man or other targets. It thus shows how standards for pollution control may be scientifically determined, and how monitoring may be used to determine dangers and enforce controls. The costs of pollution control, and the way these may — or may not — be balanced against benefits are discussed. The international problems caused when pollutants cross frontiers are described.

The general theme is admirably stated in the book's last paragraph:

> "Finally, there are grounds for optimism. There appears to be no reason why pollution should be the doom of mankind or the destroyer of the ecological balance of the world. But pollution control is an essential element in sound environmental management. The higher the standards of environmental quality and safety we demand, the more effort we shall have to make, and the more it will cost. It is a matter of wisdom and judgement how much risk is acceptable and how high environmental quality should stand amid the other goals that compete for the resources of society".

No doubt there are those who will accuse Holdgate of "complacency" for not preaching doom and gloom, but thoughtful readers will welcome his clear assessment of the national and global situation. He shows that if mankind is destroyed by pollution, it will be our own fault.

Within its limits, which I shall discuss later, this book deserves nothing but praise. It is well written, and reasonably free from jargon. It will be a godsend to lecturers in universities, polytechnics and colleges of higher education who have to give courses on pollution or pollution control. Most of them could improve their current lectures simply by reading aloud from Holdgate's text.

My only criticism of the information given is that it is not always up to date. Dr Holdgate is a senior civil servant, with the characteristic respect for his sources, particularly where these are such things as the prestigious reports of the Royal Commission on Environmental Pollution. He reproduces (as others have done) a number of their admirable diagrams. For instance, from their first (1971) report we have graphs showing the amounts of smoke and sulphur dioxide in Britain's air at different dates. These figures show the remarkable improvement in air quality between 1950 and 1968 or 1969. For smoke, we are even given the "projection" for the year 1975, four years before this book appeared. As Dr Holdgate is Director General of Research in the Department of the Environment, where there are many junior scientists who have up-to-date figures for the period since the Royal Commission reported readily available, it is a pity that the diagrams were not redrawn and updated. This is not a trivial point, for the result would have reinforced many of the book's arguments, for the figures would have shown that there has been a further, substantial, improvement in air and water quality right up to the present day.

Notwithstanding this minor fault, this is a book which deserves a wide circulation. However, I fear that its sales will be reduced by the way it has been presented by the publishers, who have not served their author well. The text is set in reasonably clear type, but it is much too small to make reading a pleasure. The sections all bear unnecessary numbers (for example, 2.5.1 Pollution in the air) which may make prospective buyers who run through the pages in a book shop think that they are being offered a government report, and so they will be put off. Finally, the price of £15 for 278 pages (with no expensive plates) will not deter the lecturer who has to deliver a course on the subject, but his students will not be able to afford their own copies. This may, of course, be welcomed by some teachers, who will be able to keep up the pretence

that their oratory arises form their own original deliberations. The book is also too costly to circulate widely among concerned members of the public who need the information to allow them to make correct decisions on environmental problems. Also, though well written, the style is of the good scientific paper, which may present difficulties to those used to lighter literature.

So, although Dr Martin Holdgate's *A Perspective of Environmental Pollution* is a fine book, valuable to the élite, it may not reach the mass audience envisaged by the publisher who wanted me to write *Pollution in Perspective*. So I fear that Dr Holdgate may not have let me off the hook, and that I may still have to write my own book. If I do, I, like all future writers on this topic, will have to thank him for marshalling so much information so admirably, and for reducing our work so considerably. □

Kenneth Mellanby is Editor of the international journal Environmental Pollution.

Pragmatic humanism

Stephen H. Schneider

The Climate Mandate. By W. Roberts and H. Lansford, Pp. 197. (Freeman: San Francisco and Reading, 1979.) Hardback £6.70; paperback £3.30.

In the past five years at least twice this number of popular books on climate has crossed my desk. Some promise ice (for example, *The Cooling*), others fire (for example, *Hothouse Earth*) and one even has the title *Ice or Fire*? Among these offerings one of the most recent, *The Climate Mandate*, is one of the best. Its authors are Walter Orr Roberts, former Director of the National Center for Atmospheric Research (NCAR) and Henry Lansford, a science writer and former Informaion Officer at NCAR. Dr Roberts is presently Director of the Program in Food, Climate and the World's Future of the Aspen Institute for Humanistic Studies. His concerns with humanity are well reflected in *The Climate Mandate*.

The team of a scientist/humanist and a science-writer has resulted in a very readable (and mercifully short — only 197 pages) selection of topics related to climate and climatic change. We are spared the uncaveated railings and pet theories of some climatic prognosticators that climatic doom is nigh as well as the bland assurance of some ostrich-like professional meteorologists that there is no climate problem worthy of public note, let alone a dozen books.

Of course, in 197 pages one cannot fully lay out the range and depth of all phases of the climate problem. *The Climate Mandate* will thus likely be only a partial help to those looking for a non-specialist textbook on climatic change to supplement, say, a beginning level college course in geography. On the other hand, it is much better than most of its competitors in confronting directly the place of climate and climatic variability in the world food picture. In fact, the book is organised to build up to the last chapter ("Defining the Problem — Malthusian Pessimists, Social Idealists, and Technological Optimists") in which the authors offer scenarios for world development within the demanding constraints of population growth, environmental stress, ideological differences, economic inequities and, of course, fluctuating climate. The scenarios comprise "the climate mandate".

To back up their solutions to the world predicament, there are chapters which review briefly climate history; the physical factors influencing climate; the climate theories of various scientists; the difficulties of climate forecasting; the respective roles of climate; technologies and infrastructure in crop productivity; and a cautious description of some weather modification operations in the US. If one extrapolates slightly from their carefully hedged remarks on weather modification, they seem to suggest that more dollars have flowed from granting agencies to weather modifiers than from seeded clouds to water users. They caution that such technological fixes are not panaceas, an apt thought in which to transition to the final chapter, where the food/population/energy/environment/climate problem (that is, the human predicament) is addressed.

The human predicament had been addressed often in the two hundred years since Malthus, and Roberts and Lansford bring it up to date with an overview of three modern contrasting views. First, there are the "Malthusian pessimists", personified by ecologist Garrett Hardin, who counsel "lifeboat ethics", whereby rich countries like the US are advised to abandon hope of feeding chronically poor countries with high population growth rates. The "technological optimists", on the other hand, believe that modern energy and capital-intensive farming can easily accommodate the foreseeable growth of world population — if only Third World governments would provide markets for farmers to sell their produce and incentives for corporations to transfer their technologies. Finally there are the "social idealists", who fear that transfer to the poor of modern large-scale technologies is another form of imperialism, as it makes the developing countries dependent on products developed and produced abroad. They counsel the overthrow of the "elites" who dominate Third World governments and the establishment of locally self-reliant, labour-intensive production systems.

Roberts and Lansford believe, as do I, that it is simplistic to view the human predicament simply as a problem of monolithic cause ("the danger lies in the conviction that a single aspect of the problem is so overriding that attempts to deal with any others are simply a waste of time and money"). They propose, instead, an approach they call "pragmatic humanism", in which we are to accept the "premise that many human lives can be saved and much misery avoided by a diversity of efforts". Technology or the Green Revolution are legitimate tools in this "whole-system approach", but their applications must meet local needs. The authors then offer "scenarios" which comprise "the climate mandate". The first element is to establish a "world food emergency reserve" and distribution system to mitigate the effects of local climatic variability. (This reviewer could hardly disagree without revoking his own writings.) Next is the need to develop agricultural self-reliance in developing nations — with US and USSR joint-help. The key to success is flexibility and cooperation on all sides. Specific examples of how to bring this about, however, are few. According to their scenarios the Earth could "have the ability to produce adequate food for a doubled or tripled world population", but they admit (and unfortunately this is the only reference to this crucial issue) that "the ecological implications have not been examined in any comprehensive way".

The authors conclude optimistically, despite the litany of obstacles they properly point out, that "if we heed the climate mandate, and if we accept the fact that the Earth's people are bound together by mutual needs and expectations that must transcend our rivalries and contests, humanity should be able not only to survive but to prevail over the hunger and starvation that have threatened so many people for so many centuries.".

The Climate Mandate is a compassionate book; it reflects the authors' own humanity. Its hopes and sentiments are appealing. But if past experiences with global cooperation remain our only reference, I would continue to rate the prospects as "technologically optimistic, but politically bleak". □

Stephen H. Schneider is a climatologist at the National Center for Atmospheric Research, Boulder, Colorado, and Editor of the journal Climate Change.

H. Stephan, G. Baron, W. Schwerdtfeger

The Brain of the Common Marmoset (Callithrix jacchus)

A Stereotaxic Atlas

1980. 73 plates, 5 figures.
Approx. 100 pages
Cloth DM 168,–; approx. US $92.40
ISBN 3-540-09782-1

Contents: Introduction.– Material.– Zero Coordinates.– Reference Coordinates.– Histological Procedures.– Shrinkage Factors.– Variability.– Standardization Proposals.– Photomicrographs for Atlas.– Presentation and Nomenclature.– Acknowledgements.– References.– Index.

Marmosets belong to the anthropoid or simian primates which include species closest to man. In contrast to other simians, the care and breeding of marmosets is relatively easy and their reproduction rate considerably higher. These characteristics make marmosets of great interest for primate research, especially as the supply of simians from the wild becomes increasingly limited.

This atlas presents 73 photomicrographs of serial sections from the brains of common marmosets. Taken at 0.5 mm intervals, the sections are stained for both cells and nerve fibers and shown on facing pages for comparison. Stereotaxic coordinates are labelled in detail and methods for their standardization discussed.

The accuracy of the stereotaxic descriptions provided here will greatly aid researchers using marmoset brains for neurophysiologic, neuroanatomic, neurochemical and behavioral investigations.

J.T. Enright

The Timing of Sleep and Wakefulness

On the Substructure and Dynamics of the Circadian Pacemakers Underlying the Wake-Sleep Cycle

1979. 103 figures, 2 tables.
Approx. 290 pages.
(Studies of Brain Function, Volume 3)
DM 49,–; approx. US $27.00
ISBN 3-540-09667-1

Contents: Introduction.– A Description of Activity-Rhythm Recordings and Their Implications.– The Pacemaker and its Precision.– A Class of Models for Mutual Entrainment of an Ensemble of Neurons.– A "Type Model" and Its Behavior. Partial and Loose-Knit Mutual Entrainment.– Precision of Model Pacemakers.– Influences of Constant Light Intensity.– A Brief Detour: Further Thoughts About the Discriminator of the Models.– General Features of Entrainment: The Type Model.– Responses to Single Light Pulses. Part I: Nocturnal Rodents.– Responses to Single Light Pulses. Part II: Diurnal Birds.– Plasticity in Pacemaker Period: A Dynamic Memory.– Predictions from Coupled Stochastic Systems.– Further Predictions: A Modest Success and Two Problem Cases.– Morphology of the Models: Where is the Pacemaker? – A Reprise and Synopsis: On the Advantages of Apparent Redundancy.– Subject Index.

J.-P. Ewert

Neuroethology

An Introduction to the Neurophysiological Fundamentals of Behavior

Translated from the German by W.L. Gray
1980. 171 figures, mostly two-colored, 1 in four colors, 9 tables.
Approx. 340 pages.
DM 49,–; approx. US $27.00
ISBN 3-540-09790-2

Contents: What is Neuroethology.– How Does a Stimulus Elicit Muscle Contraction? – Key-Stimuli and Releasing Mechanisms: Some Fundamental Concepts in Ethology.– Neurobiological Basis for the Recognition and Localization of Environmental Signals: How Does a Toad Brain Recognize Prey and Enemy? – Functional Areas in the Visual System of Vertebrates: Comparative Aspects.– Examples for Release and Control of Behavior Patterns by Other Sensory Systems.– Neuronal Circuits for Fixed Motor Behavior Programs.– Central Representation of Behavior Motivation.– Methodological Appendix.– Special References.– Suggested Reading.– Subject Index.

The content of the highly successful German original has been up-dated and expanded in this translation with new illustrations and recent experimental findings.

Howard Florey

The Making of a Great Scientist
Gwyn Macfarlane

Howard Florey came to Oxford from Australia as a Rhodes Scholar in 1922, determined to make a career in scientific medicine. His inspiring drive and unerring flair for research enabled him to found one of the best schools of experimental pathology in the world and to overcome tremendous difficulties to make penicillin therapy a reality. This biography, based on extensive research, is a study of the personal and professional qualities that are needed for such scientific success at the highest level of achievement. Illustrated £7.95

Cosmical Magnetic Fields

Their Origin and their Activity
E. N. Parker

This book explores the universal spontaneous generation of magnetic fields in astronomical bodies and the agitation of the bodies by those fields. The properties of magnetic fields, their appearance throughout the astronomical universe, and the havoc they wreak are described in physical terms, and the theoretical effects are demonstrated with formal mathematical illustrations from the basic electromagnetic equations. £45
International Series of Monographs on Physics.

Spin Temperature and Nuclear Spin Relaxation in Matter

Dieter Wolf

The basic theories of nuclear spin relaxation due to atomic, molecular, and defect motions in solids, liquids, and gases are reviewed from a common viewpoint. This leads to the formulation of a unified spin-temperature theory of nuclear spin relaxation which is applied to phenomena such as diffusion and molecular reorientations in crystals and liquids, quadrupolar effects associated with lattice defects, and electronic effects in metals and semiconductors. The author hopes that this book will make it easier for experimentalists to analyse NMR relaxation data and thus encourage a broader use of NMR techniques in solid-state physics and materials science. £15 *International Series of Monographs on Physics*

Mushrooms and Toadstools

A Field Guide
Geoffrey G. Kibby

This book will supply the need for a really effective identification guide to British and European fungi. There are sections on the structure, classification, and reproduction of fungi. The identification section consists of 100 pages of full-colour drawings, each page faced by detailed descriptions of the species illustrated, in taxonomic order. £7.95 *Oxford Paperbacks* £4.95

Circle No. 35 on Reader Enquiry Card.

The Prehistory of Polynesia

Jesse D. Jennings, Editor

International experts on Polynesian archaeology and anthropology tell the story of Polynesia from its origins to the first encounter with Europeans. The book moves chronologically from the early Lapitan villages to Fiji, Samoa/Tonga, the Marquesas, Easter Island, Hawaii, the Society Islands, and New Zealand. Further chapters explore the contemporary Polynesians and their environment.

Companion to Biochemistry Volume 2

Selected topics for further study
Edited by A T Bull, J R Lagnado, J O Thomas and K F Tipton

This volume runs alongside the existing *Companion to Biochemistry*, and covers topics not dealt with in the first volume. Both books bridge the gap batween basic texts and specialist reviews by providing a collection of articles on various important aspects of biochemistry. Sixteen specialists have contributed to *Volume 2*, which will be of value to advanced undergraduates of biochemistry.

Nuclear detective story

J.H. Fremlin

Nuclear Disaster in the Urals. By Zhores A. Medvedev. Pp.214. (W..W. Norton: New York; Angus and Robertson: London, 1979.) $12.95; £5.95.

DR MEDVEDEV has spent much time in studying widespread but indirect information about a very serious nuclear accident which occurred in the Urals, seemingly around 1957. His book begins with an extensive account of the hard and ingenious detective work which was needed to extract information from seemingly irrelevant papers on radioecology published in Russia, often years after the event. He gives an impressive picture both of the all-pervasive thoroughness of the censorship and at the same time of the number of points which nevertheless slipped through, and from which he has built up a convincing picture of serious contamination over a large area on the eastern side of the southern Urals where the original Soviet military nuclear industry was situated.

Dr Medvedev seems unnecessarily anxious to establish his excellent case for the reality of the disaster, and his arguments are not always individually convincing. For example, he says that papers written during the following few years on the radioecology of the region purported to describe the take-up of radioactive material, especially ^{90}Sr (strontium-90), by plants and animals and the food chains connecting these. To do this properly, he claims that less than 10% of the animals concerned could have been trapped or shot without disturbing the ecology which it was desired to investigate. This is hardly relevant, at least in the short term, for deer which are at the end of a chain (assuming that human hunters are not to be sampled). Using this figure of 10%, he deduces that the area contaminated must have been at least ten times the area found by dividing the number of deer shot, by the average population density. It could however, have been intended to shoot 100% of the larger contaminated ungulates, to prevent them from migrating to regions where they might later be shot and eaten. In this case one would deduce a maximum area ten-times-smaller than Medvedev does.

The book has clearly been written rather hurriedly, leading to some errors. For example, on page 173, he states that ß-particles can penetrate 2 — 8 cm into living tissue and he (or the translator) has missed a misprint of protons for photons. More seriously, on page 74, he defines the permissible dose of radiation as being the amount that is assumed not to cause harmful effects, and on page 21 says that the next generation will suffer severely if they are born from parents with ^{90}Sr in their bones. This and its daughter product ^{90}Y (yttrium-90) are both pure β-emitters with a range of only a few millimetres in tissue.

In spite of these minor errors, I accept without reservation that a major accident must have happened around 1957 which contaminated probably tens and conceivably hundreds of square kilometres — to a level of 1000-4000 Ci/km^2. For the reason given above, I do not accept the numerical estimate of 400 square kilometres of heavy contamination, but there seems no doubt that Dr Medvedev is right in describing the event as a major disaster, and that this was connected, like our Windscale reactor fire, with the military production of plutonium for bombs.

The final sixth of the book is speculative. The censorship has successfully hidden the cause of contamination. The US intelligence services may know the truth, but the thoroughly "sanitised" documents extracted from the CIA do not divulge it. Accordingly Dr Medvedev has had to rely on hearsay. Early guesses by local but uninformed people included an accidental bomb explosion and an escape of material from a runaway reactor. A third guess is that the wastes left after extraction of plutonium and unsatisfactorily stored, exploded. At first sight either of the first two seems possible and the third seems impossible on thermodynamic grounds, for the same reason that you cannot make a good fire with the ashes of an earlier one. Nevertheles, this is the theory that Medvedev espouses, and as his arguments are plausible they need to be examined.

The major positive argument is the size of the area affected. In each square kilometre the ^{90}Sr observed was of the order of that produced by the fission of a kilogram of uranium or plutonium. By 1957 the accumulated wastes could have sufficed to cover 400 km^2 if an adequate distribution mechanism existed. So could a 'dirty' H-bomb, with no distribution problem; but a fire in a runaway reactor could hardly do so. The actual area covered by heavy contamination is therefore important.

The second argument is the low ratio of ^{137}Cs to ^{90}Sr which varied from 1:8 (in a lake) to 1:1000 in soil, instead of the roughly 1:1 expected from fission. Dr Medvedev suggests that most of the ^{137}Cs had been removed from the wastes for industrial or medical use. The large difference between lake and surface soil, however, looks much more like the result of leaching away of the mobile caesium in the soil leaving the less mobile strontium near the surface.

The chief argument against the waste-explosion theory is the impossibility of producing an explosion which would pulverise the (non-volatile) material to the 1—10 μm sized particles needed to spread it over hundreds of square kilometres. Such an explosion would have to be of the same order as the Bikini H-bomb test and is not consistent with the type of steam explosion that could arise due to water running into radioactively heated waste. This could throw a lot of material for hundreds of metres but could not produce the fine pulverisation of the whole mass of material needed for its uniform distribution.

Dr Medvedev's alternative source of energy lies in the plutonium with which the wastes are invariably contaminated. At the Hanford works in Richland, Washington (one of the largest atomic plants in the US) some 100 kg of plutonium was concentrated over a decade, by a process equivalent to chromatography, in the topmost layer of mud in the trenches into which liquid wastes were run. This process might indeed eventually produce a critical concentration and this could support a chain reaction. This would, however, necessarily start slowly with a "delayed-critical" concentration in wet material, as the plutonium could not be chromatographically concentrated in the dry. This reaction would probably raise the temperature and reduce reactivity to equilibrium values at which plutonium was burnt as fast as it was added. At most it could raise the temperature only so fast (the delayed doubling time being several seconds) as again to produce a steam explosion. It is difficult to see how this could reach the effect of even a ton of TNT and quite impossible to see how it could reach the megaton scale required to contaminate hundreds of square kilometres.

Although the visible flash lighting up the sky reported by the CIA in 1955 (page 195) is consistent with an accidental H-bomb explosion, I do not think this the only possible explanation of the facts. I am unconvinced by Dr Medvedev's ecological arguments that the area involved was 400 km^2, and a very respectable smaller area could have been contaminated to the level observed by an uncontrolled reactor fire in which a large part of the uranium fuel was burnt and dispersed with the smoke of burning carbon moderator. Dr Medvedev realises himself that there are difficulties with any of the mechanisms proposed for a waste explosion. In his own words (page 163), "Truly, scientific imagination (or a capacity for 'science fiction' if you will) is needed to construct hypotheses about the exact causes of the explosion". I can only agree. But I hope a lot of people will read the book and see whether they agree too. (I congratulate the translator.) □

Unorthodox epidemiology

D.A.J. Tyrrell

Diseases from Space. By Fred Hoyle and Chandra Wickramasinghe. Pp.196. (Dent: London, 1979.) £6.95.

THIS is an unusual book. It is well produced and easy to read, being written in a narrative and popular style; but its six chapters and three appendices are apparently intended to be a serious presentation of a theory put forward by the authors. The subject matter ranges widely. They start with cosmology and their interest in the organic molecules to be found in interstellar space. They suggest that life may have evolved in cometary bodies composed of organic chemicals, which would have had an inner zone protected from radiation and warmed to about 10°C by internal chemical reactions. In this "pool", primitive life-forms like bacteria and viruses evolved and then, when the comet passed near the Earth, were shed into space as micrometeorites, protected from ultraviolet radiation by a coating and sufficiently small not to be overheated on entering the Earth's atmosphere. They then sank towards the Earth, were carried on down to its surface by storms, and thus initiated biological life in the primeval Earth. They further assert that the process continues and that clouds of viruses, particularly those of influenza and the common cold, rain down upon the Earth and cause epidemics of these diseases; and that epidemics of smallpox, and of bacterial diseases like cholera and plague, may occur in the same way.

The authors have obviously read widely and thought deeply, and I am unable to express a useful opinion on their theory of the origin of life. However, as they extend the theory to explain epidemics, this can be examined in relation to present knowledge of infectious diseases. For instance, they argue that influenza viruses descend from space and are breathed in by birds, animals and man, and that the transmission from person to person or animal to animal is unimportant. They do not explain how an organism which must have produced untold billions of particles in a cometary puddle in space (and which they suggest may have arrived on Earth inside a bacterium) was also exquisitely adapted to replicate in avian and mammalian cells. The influenza virus has specific functioning elements by which it penetrates membranes, involves the cell nucleus, is replicated in ribosomes and forms new particles by inserting viral protein into the cell membrane which then bulges out and envolopes the virus nucleic acid and other peptides lying in the cytoplasm beneath. In Earth laboratories many common cold viruses, rhinoviruses and coronaviruses multiply only in human cells, and only some such cells — in what sort of cells do they replicate in space? The influenza viruses found around 1930 have almost exactly the same internal peptides as those that circulate now — does all influenza come from one cloud of meteorites?

A key fact of their argument is that they have looked at published literature, investigated outbreaks of influenza in schools and found no evidence that influenza spreads from person to person. They state that if influenza did spread in this way it would be distributed in the children in a school by a random process. They show that it is not random — at Eton some houses were heavily affected and others virtually free, as judged by clinical diagnosis — so they prefer the earlier theory that influenza is due to a "miasma". It is stimulating to have current thinking challenged in this way, but I doubt if their theory provides a better model to explain known facts than do our present concepts. There is evidence that different individuals shed varying amounts of virus, so in small groups they would be expected to infect at different rates — and I think the spread of the recent H1N1 virus from China across the USSR, and to Hong Kong and across the world, is better explained by spread from person to person than by viruses descending from space first in one area and then in the next. I would expect an influenza virus coming from space to appear over a very wide area if it really has to sediment slowly and negotiate the jet streams as the authors describe, even if it does survive desiccation and ultraviolet radiation.

I cannot agree with the theme of the book, which smacks more of science fiction than of science, but I think it is good that it has appeared. I would hate to think that unorthodox views could be suppressed, or that authors could never be published if editors or reviewers did not like their work. □

US politics and the test ban

Edward Bullard

Blowing on the Wind: The Nuclear Test Ban Debate, 1954-60. By Robert A. Devine. (Clarendon/Oxford University Press: New York and Oxford, 1978.) £7.95.

THIS book is a detailed account of the reactions of US politicians, scientists and the public to the attempts to stop tests of nuclear weapons. It is confined almost entirely to the time when Eisenhower was President (1952-60) and is a political and sociological study rather than a technical discussion. Technical questions are mostly dismissed with the statement that some scientists said one thing and others said the opposite.

To have the events, and the views of the people concerned, set out in chronological order is useful. There are some well-documented judgements that run counter to widely held beliefs; for example John Foster Dulles appears as a strong and consistent supporter of a test-ban.

Useful as it may be, the book makes dull reading. This is, in part, due to the almost exclusive concentration on US views; negotiations require at least two parties and the interest lies largely in the contrast of aims and methods of the two sides. The extent to which this book ignores all non-US participation is lamentable. The only references in the bibliography to publications by non-American authors are to Khrushchev's memoirs (transcribed and edited in the US), *Sakharov Speaks* (also a US publication) and Harold Macmillan's memoirs. The last of these is the only item in the bibliography that is not published in the US. It is, of course, difficult to understand the motivations and internal struggles of a closed society, such as the USSR; it is, however, important to make the effort. The first route to understanding is the study of official pronouncements and propaganda. If propaganda loses touch with the real world and with real intentions, it loses plausibility and becomes unconvincing to those it is intended to influence or deceive. For example, it was possible to follow the German retreat across Russia in 1944 by noting the westward progression of the locations of alleged German victories. For the Russian views on the test ban there is much more evidence than propaganda.

The 1958 'expert' discussions hold a special place as the first discussions with the Russians in which there was any real meeting of minds. Stalin had been dead for 5 years and Khrushchev had consolidated his power. There was a new situation in which Russian good faith and intentions had to be assessed anew. These matters are inadequately dealt with by the author who seems to have read only the final agreed report and not the transcripts of the day by day discussions, which are much more instructive.

The 1958 meetings were also of interest from another point of view. The American delegation consisted of a mixture of Hawks

and Doves who had not reached agreement on a 'party line' before setting out for Geneva. The reason for this probably lay in Eisenhower's belief in consensus and dislike of controversy and of having to decide between contesting parties. The meetings of the western delegates were often difficult. Most of those present were interested in assessing Russian intentions and motives, but the Hawks were primarily concerned to prevent any kind of agreement wiht the USSR. They even maintained, for a while, that atmospheric tests could not be sufficiently monitored because the wind might blow round and round in circles and never carry the radioactive debris out of Russia. By confining himself to published sources and Presidential papers the author has missed the details of these interesting controversies. He seems not to have discussed the negotiations with any of the participants.

The breakdown of the negotiations for a complete test-ban came in the political talks late in 1958. The US withdrew its support for the conclusions of the 'experts' concerning underground tests, introduced hastily analysed data from recent tests and declared that the technical matters must be discussed *de novo*. This interesting situation is very inadequately discussed and no references are given to Russian views; for example, to the detailed discussions by Riznichenko.

Throughout the book the discussion of technical matters is marred by an apparent lack of interest in the meaning of numbers. For example, on page 103 it is stated that Willard Libby calculated the amount of Sr-90 in the atmosphere to be 24 megatons. It is doubtful if every reader will understand this oracular statement. Much more confusing are the two values given for the amount of Sr-90 in the soil of the US in 1958 (pages 263 and 272); these differ by a factor of a million. The larger of them is a factor of 1000 less than that given by the AEC for 1961 in *Effects of Nuclear Weapons*. This muddle may be connected with the author's belief that m is the abbreviation for micro.

Perhaps I have been unduly severe, the book is about American politics and my complaints are that it is not about other aspects of the subject. It does unearth some fascinating things, such as a remark made in 1958 by a member of the President's Scientific Advisory Committee. He (who was he?) is said to have said: "These men who don't want a test moratorium are like a kid you are trying to put to bed. First he wants a drink of water and then he wants to go to the bathroom, but what he really wants is not to go to bed". □

Sir Edward Bullard is an Emeritus Professor of Geophysics of the University of Cambridge, UK, and of the University of California at San Diego. He attended the 1958 Geneva discussions on the possibility of a test-ban treaty.

Commitment to logic

Aaron Novick

Origins of Molecular Biology: A Tribute to Jacques Monod. Edited By A. Lwoff and A. Ullmann. Pp.246. (Academic: New York and London, 1979). $17.50; £11.35.

MOLECULAR BIOLOGY had its origins in several centres which served as gathering places for people from around the world. In the very beginning, it was Cold Spring Harbor in New York and soon after the Institut Pasteur in Paris and the MRC Laboratory in Cambridge, among others. These places developed for a variety of reasons not the least important of which was the presence of some of the leading figures in this new field. At the Institut Pasteur it was André Lwoff, Jacques Monod and Francois Jacob. Jacques Monod died in 1976 and a number of his colleagues and disciples have contributed to this *Tribute*, a volume which describes from a number of points of view an exceptional person who played one of the major roles in the development of our present understanding of the control of gene expression. From its title, it seems to be a companion volume to *Phage and the Origins of Molecular Biology*, edited by J. Cairns, G.S. Stent and J.D. Watson (Cold Spring Harbour Laboratory, 1966), a volume dedicated to Max Delbruck on his sixtieth birthday.

The personal accounts in volumes such as these provide descriptions of important and fascinating details in the development of scientific ideas never reported in the usual forms of publication. Because of its memorial character, the present volume includes many personal details in its descriptions of a man of great spirit whose life outside the lab as well as in it was of heroic scale, whose friends included scientists and public figures throughout the world.

Of particular interest is the collection of personal statements from most of the people involved in the series of discoveries which culminated in the giant step represented by the Jacob-Monod model for gene expression and regulation. The reports provide a fine illustration of the development of a great scientific idea, but one must recognise that the picture is limited by the modesty of some of the participants in this memorial volume. André Lwoff and Francois Jacob were no less important both to the exciting and creative spirit at the Pasteur and for their own remarkable scientific contributions. As a history, the volume does not make it adequately clear that the critical experiments which showed that control of the *Lac* gene occurs through action of an endogenous repressor could be done only because of Jacob's timely development of the necessary genetic technology.

It is also fascinating to follow the development of Monod as a scientist. Here is a man for whom science was a great personal adventure and a means of personal expression, yet a man fervently dedicated to logic and reason. He exulted in the power of deduction and was known to shout after an observation verified one of his deductions that this was again proof that Descartes was right and Kant wrong. Despite his commitment to logic, he had a remarkably successful intuition for how things must be, and he could present these pictures with great force. Even when he was later proved wrong, the vehemence and sharpness of his argument expedited the clarification of a problem.

Some of the authors also note his audacity. He never limited himself to the disciplines of his education nor did he ever restrict himself to minor objectives. In his crowning work, the development of the allostery model for regulatory proteins, despite being trained as a zoologist he used modern physical chemical ideas with no inhibitions to formulate a remarkably original and innovative theory. "It is no longer a question of right or wrong", one of my colleagues in the field remarked. "The Monod theory has changed the style of thinking among the biochemists."

An impressive feature of the volume is the honesty of some of the reports which describe the personal faults as well as the greatness of Monod. His enthusiasm and pursuit of fundamental problems inspired the people he worked with. His candour came as an exciting surprise when it was first encountered by his disciples. This lack of stuffiness along with his generosity and the confidence he placed in his students created love and great loyalty. But he also had personal faults, and these too are reported. He could be vain and arrogant in a pointless way. Surely it is because they held him in such high regard that his colleagues were free to describe these faults so honestly.

As occasional allusions in the volume indicate, Monod's life outside of science was also remarkable. He was aware, wise and, when he felt it necessary, active in the world of politics. During the hysteria in the United States in the early 1950s, when foreign visitors were required to sign non-communist affidavits, the *Bulletin of the Atomic Scientists* published statements by a number of European scientists; I recall that by far the best of these was the one by Monod, who with characteristic perception saw the larger implications of US policy. Again, on the occasion of the Nobel Prize, rather than basking in the adoration and pride the French have for their Nobel Prize winners, he took advantage of the public attention to improve the support of science in France by making a strong public statement severely critical of his government's science policy,

a statement which apparently infuriated DeGaulle.

Some contributors make reference to Monod's service during World War II in the Resistance and later in the re-established French Army, but the volume's guidelines prevented fuller description of these parts of his life, for the same reasons the authors say little about Monod's significance as a public philosopher, illustrated by his book, *Chance and Necessity*, which was a sensational bestseller in France.

The essays are generally of exceptionally high quality, and they will bring back memories of great times for the large number of scientists throughout the world who have spent time with Jacques Monod and his colleagues in those laboratories built originally for Louis Pasteur. It will also bring the pleasure of enlightenment to many others who were not directly involved. In addition, for those totally outside of molecular biology, it is a worthy addition to the developing literature on the origins of this field which has so revolutionised biology. And this appearance of a memorial volume ought to stimulate interst in a more complete biography of this impressive man whose life touched so many of the important developments of the middle decades of this century. □

Aaron Novick is Professor at the Institute of Molecular Biology at the University of Oregon. He spent 1953-54, 1962-63 and 1967-68 in Jacob and Monod's laboratories.

Challenge to promissory materialism

Anthony Flew

The Human Mystery. By John C. Eccles. Pp. 255. (Springer International: Berlin, Heidelberg and New York, 1979.) DM34.

EVEN had Sir John Eccles not begun this his own first series of Gifford Lectures with quotations from "My great master, Sherrington" (page 2) any sympathetic reviewer would have been bound to refer to the fitting facts that it was just 40 years earlier, under the same foundation and in the same University of Edinburgh, that that "great master" himself gave the lectures which were later to become *Man on His Nature* (Cambridge, 1940). *The Human Mystery*, though thoroughly worthwhile, lacks the magic of that predecessor: how could it not? The present Eccles project, of which we have here only the first and probably less distinctive half, is strictly in accordance within the terms of Lord Gifford's will: ". . . to promote and diffuse the study of Natural Theology in the widest sense of that term — in other words the knowledge of God".

The aim is to mount a challenge to what, following his friend Sir Karl Popper, he calls "promissory materialism", a challenge along the entire front but with the main weight concentrated in the sector of his own lifelong concentration, the human brain. Promissory materialism is defined as the "claim that science is so powerful and pervasive that in the not too distant future it will provide an explanation in principle of all phenomena in the world of nature including man, even human consciousness in all its manifestations" (page 7). So, after a first introductory lecture, Eccles proceeds through the "Origin and Evolution of the Universe", the "Planetary System and Planet Earth", the "Origin of Life and Biological Evolution", to "Human Evolution: The Story of Cerebral Development". It is in the second half that we come to the real speciality of the house: "Cultural Evolution with Language and Values: The Human Person"; "The Creation of a Self"; "Structure of the Neocortex: Conscious Perception"; "Learning and Memory"; and "The Mind-Brain Problem".

To the scientific layman the story which Eccles tells in his first half is fascinating, though here and elsewhere to follow him closely requires frequent consultation of those handy Penguin dictionaries of the sciences: if he has succeeded in his attempt "to present scientific material . . . with a minimum of technicality", then one must pray to be spared the failures.

The Gifford aspect appears at once in "the Big Bang story as suggesting the operation of a supernatural Creator" (page 15); although it is curious that Eccles mentions only in an aside the notion of a Creator upon whom — whether or not, He, or She, 'in the beginning' also started the Universe off — it continues to be always absolutely dependent. After all, it was precisely and only continuous creation in this theological sense which St Thomas insisted could be known on the basis of natural reason, without benefit of revelation.

Two other Gifford points stressed in the first half are the unpredictable chanciness of the emergence of life, and of the actual course of biological evolution; and the fact that the whole cosmological story would have had to be very much as it has been if beings capable of knowing that story were going to become part of it. About the former Eccles maintain, and surely he is right, that "There is no predictable line of evolutionary development" (page 49). It seems to be as true of the evolutionary biologist as of the human historian that most of his most important explanations are of how something was possible, rather than of why it was inevitable. No doubt other readers will share my own pleasure in two pieces of Eccles mischief: the suggestions that the most primitive mammals "brought about the dinosaurs' downfall by preying on their eggs" (page 58); and — of "the attempt to communicate with super-intelligent humanoids in our galactic system" — that it is "highly likely that this romantic project will be killed by boredom" (page 73).

In wondering what to make of the second of the two points stressed in the first half we must give some weight to the point, which Eccles does not notice, that these conclusions are derived only for a Universe obeying the same fundamental laws of nature. The argument is that "If we economise and have the Big Bang producing the mass for one galaxy of 10^{11} stars, which is still an immense universe", then, given what we now know of the fundamental laws of the actual Universe, "the time from Big Bang to Big Crunch is reduced to one year" (page 28). But a Creator, having it in mind to furnish his creation with potential knowers, would not, presumably, be restricted either to or by any actual or possible natural laws.

In his rather longer second half Eccles is at least equally fascinating. In lecture 6 he begins by contending, as is surely correct, that "cultural evolution is exclusively human" (page 98). This and much of the later discussion is presented in terms of Popper's distinction between "three Worlds: World 1, the matter-energy of the cosmos; World 2 of all subjective experiences; and World 3, which is the cultural heritage of mankind" (page 98). The reader needs to be aware always, as their spokespersons so often are not, that the second and third of these can be identified only as aspects of the first. We have, that is to say, no knowledge of any kind of consciousness other than the consciousness of organisms; and perhaps we cannot even give sense to talk of any consciousness that is not thus rooted in the matter-energy of World 1. The whole cultural achievement of World 3 is likewise embodied in, and inseparable from, such incontestably World 1 objects as buildings, books and computer tapes.

In the rest of this lecture Eccles considers the enormous importance of language and — what could not exist without language — the self-consciousness which is so much more than mere consciousness. As one expression of his constant and most welcome concern to resist the *1984* which is "engulfing more and more of our planet" (page 237), and after crediting to the Sumerians the two incomparably important inventions of both writing and the wheel, Eccles remarks that for most of its history Sumer "was an amazingly open and tolerant society" (page 114); though it does not occur to him that those market

Announcing!

Both in its theoretical and applied aspects, interest in ecology is developing rapidly. However no single ecology text-book is likely to satisfy fully the needs of the student. This new series has been designed therefore to offer a variety of small volumes, written by acknowledged experts in the field, each on a topic of fundamental importance.

The first two titles are now available.

OUTLINE STUDIES IN ECOLOGY

Series editor: G M Dunnet and C H Gimingham

Island Ecology M Gorman

This book presents a concise review of current studies in Island Ecology, considering both real islands surrounded by oceans, and habitat 'islands' surrounded by more or less inhospitable terrain. The author emphasizes the highly dynamic nature of island biogeography. Students of ecology and conservation at all levels will find this a readable and well-illustrated introduction to island studies; the many references will provide a valuable guide to the original literature.
October 1979 216 × 136 mm 80 pages
Pb Illustrated 0 412 15540 0 £1.95

Vegetation Dynamics J Miles

An awareness of how and why plant populations change with time is essential for the effective management and conservation of all types of vegetation. This is the first book to provide a comprehensive introductory account of the subject, bringing together material from a wide variety of sources in a balanced discussion of the nature of vegetation and its enormous variability with time. The book is well-illustrated, and contains more than 300 references.
October 1979 216 × 136 mm 80 pages
Pb Illustrated 0 412 15530 3 £1.95 Sixth Edition

Selective Toxicity A ALBERT
The physico-chemical Basis of Therapy

Selectivity is the most important consideration in the development of chemical agents necessary for the control of disease, whether of man, animals or crops. The sixth edition, while preserving the general structure of the fifth, has again been revised and extended to take account of recent developments in the field. The text is liberally illustrated and the comprehensive reference section covers the whole history of the development of selective drugs.
November 1979 252 × 159 mm about 600 pages
Illustrated Hb 0 412 15650 4 £15.00

Biological Energy Resources M SLESSER and C LEWIS

This book provides a concise account of how energy from the sun is captured by plants through photosynthesis, and the subsequent conversion of these plants into fuels for use by man.
Beginning with an introduction to the nature of solar energy and its role in photosynthesis, the authors continue with a discussion of the different technologies available for the conversion of this energy to a form utilisable by man. These include direct combustion to obtain heat, chemical treatments yielding solid, liquid and gaseous fuels, and microbiological processes leading to alcohol and methane production.
October 1979 240 × 159 mm 200 pages
Illustrated Hb 0 419 11340 1 £8.50

Theoretical Statistics D R COX and D V HINKLEY

This book provides a systematic statement of the theory of statistics with emphasis placed on general concepts rather than on mathematical rigour. Now available in paperback for the first time, this book will be of interest to all who are seriously concerned with the theory of statistics.
September 1979 240 × 159 mm 524 pages
Pb 0 412 16160 5 £6.95

Receptors and Recognition GREAVES
Series A Volumes 1-6
Edited by P CUATRECASAS and M F

Review volumes providing comprehensive coverage of important advances in studies of the cell surface and biological recognition systems.
Now available as a set of six paperback volumes.
October 1979 0 412 14280 5 Illustrated £30.50

Some Basic Theory of Statistical Inference E J G PITMAN

In this book the author presents with elegance and precision some of the basic mathematical theory required for statistical inference, at a level which will make it readable by most students of statistics.
September 1979 222 × 141 144 pages

FROM THE MACMILLAN PRESS

New Titles

THE ECOLOGY AND CONSERVATION OF LARGE AFRICAN MAMMALS
S. K. Eltringham, with a foreword by Sir Peter Scott CBE DSC
"The flora and fauna of Africa are one of the greatest wonders of the world. Mankind has a responsibility to assure their continued existence and I believe this book will significantly help to do just that." *Sir Peter Scott*
A scholarly but readable account, summarising the findings of the many wildlife research stations at work in Africa.
£15.00 0 333 23580

EVOLUTIONARY ECOLOGY
Bernard Stonehouse and Christopher Perrins
Available for the first time in paperback
"This is a book which every keen amateur naturalist should read." *Oxford Mail.*
21 essays in honour of Dr. David Lack. They cover four main areas; Population regulation and Function of territory, Feeding adaptions and Ecological segregation, Breeding adaptions and Reproductive rates, and Behaviour, Adaption and Taxonomic relationships.
£5.95 0 333 281626

DECISION MAKING FOR ENERGY FUTURES: A case study of the Windscale inquiry.
D. W. Pearce et al.
Who decides the Scientists and Technicians or the Politicians?
Using the application by BNFL to set up an oxide fuel reprocessing plant at Windscale the authors of this study examine the ways in which our energy future is being decided.
The come to some controversial conclusions. They believe that national issues are being removed from democratic control as a result of their deliberation outside parliament and within the bureaucratic planning machinery.
£10.00 0 333 274385

A DICTIONARY OF THE ENVIRONMENT
Michael Allaby
Now in PAPERMAC
DEFINES SOME 6,000 WORDS AND PHRASES.
"The rapidly evolving vocabulary of any one of the life or earth sciences ... can be bewildering both to the lay reader and the specialist trained in another field. Michael Allaby's *A Dictonary of the Environment* attempts to cover them all, and to appeal to lay reader and scientists alike." *Richard Clarke-Nature*
£3.95 0 333 274490

To be published in February 1980

GROWTH WITHOUT ECODISASTERS
N. Polunin
The environment is under attack. Its resources have been plundered to sustain industrial and technological growth. If growth is to continue and man is to live in a pleasant and healthy environment its use must be carefully planned and controlled.
The 18 chapters in this book are based on the keynote papers, and the discussions that followed them, presented at the 2nd International Conference on Environment Future held at Reyjavik in 1977. Papers, each of which was presented by a specialist in the field, range from Fresh waters and their biota to Life-style alternatives and the Ethics of biospheral survival.
£17.00 0 333 235515

THE CHAIN STRAIGHTENERS: FRUITFUL INNOVATION – THE DISCOVERY OF LINEAR AND STEREO-REGULAR POLYMERS
Frank M McMillan
The story of the remarkable burst of scientific discovery and technological innovation that gave science mastery over the 3-dimensional structure of high polymers and the world its most useful group of plastics and synthetic rubbers. A story surrounded by controversy, where science meets big business and powerful personalities clash. This will undermine many of the conventional views of scientific innovation.
£9.00 0 333 259297

FROM DNA TO PROTEIN: The Transfer of Genetic Information
Maria Szekely
This is the first textbook which discusses gene structure on the basis of recent discoveries of overlapping and split genes and which gives a consistent image of the ways in which genetic information can be encoded into the genetic material and how it can be transfered to other materials.
A perfectly up-to-date account of our present knowledge of the structure and expression of genes in prokaryotic and eukaryotic organisms and the only available text showing the correlation between the structure and function of nucleic acids.
£14.00 0 333 218361
£6.95 0 333 218388

CHEMISTRY FOR THE LIFE SCIENCES – 2nd edition J.C. Dawber and A.T. Moore
An integrated chemistry text intended for undergraduates studying science subjects other than chemistry.

MACMILLAN PRESS

Circle No. 51 on Reader Enquiry Card.

interests which he was earlier inclined to chide might have been one necessary condition of this tolerance (page 110).

Lecture 7 examines "the role of World 3 in producing the next generation"; making much, but never too much, of the crucial fact that it is thanks to this that "The creation of a cultured person" can now "be accomplished in a few years", whereas "it took at least 50,000 years to create a high civilisation" (page 123). This chapter contains one section which will especially delight any philosopher who has ever faulted Hume's *Treatise of Human Nature* for its "paralytic's eye view of causation": Eccles tells of experiments with kittens in gondolas which show that exploratory learning will not take place without active movements by the learner (page 132).

Lecture 8 on "Conscious Perception" constitutes necessary preparation. In lecture 9 on "Learning and Memory" the thesis is that memory is essential to anything deserving to be called knowledge: "Without memory there could not be a knowing of existence" (page 180). In lecture 10 Eccles wants to construe mind and brain as "independent entities, the brain being in World 1 and the mind in World 2 (Fig. 6-1)", and to urge that these are both entities which "somehow interact, as illustrated by the arrows in Figure 10-2" (page 212).

But this, as the rally-drivers say, is going a bit quick. For all our ordinary talk about minds, ordinarily understood, is just talk about certain sorts of things which some creatures of flesh and blood can and do do or suffer. To say that, for instance, she has a first-class mind just is to say that she is capable of operating at that high academic level. So if anyone wants to hypothesise some independent entities to be called minds, he has first to provide some account of how such entities are to be identified and individuated. For minds in the common everyday sense of the word are not what is required: they are not, that is to say (logical) substances — things which, like chairs and tables and unlike grins and tempers, could significantly be said to exist separately and in their own right. To speak of her first-class mind surviving her death and cremation would, in the everyday sense of 'mind', be about as sensible as speaking of the grin on the face of Alice's Cheshire Cat outlasting the cat of whose face it was a configuration. On the other hand, much of the history of philosophy since Descartes can be read as showing how difficult if not impossible it must be to think up a notion of minds as immaterial substances; which could be identified as subjects of discourse, re-identified through time, and individuated one from another. □

Precious cult of scientific knowledge

Martin Pollock

Paradoxes of Progress. By Gunther S. Stent. Pp. 231. (Freeman: San Francisco and Reading, UK, 1978). Hardback £8; paperback £3.90.

THIS is a collection of articles on modern science, already published over the past ten years or so and now strung together, a little forcedly perhaps, under a title which can serve a multitude of themes. It is therefore, inevitably, somewhat of a ramble. The common thread is Professor Stent's own idea of what is happening to our precious cult of scientific knowledge, where it is going and what its principles mean, or should mean, for us. His opinions are worth studying, though cramped by a rather awkward style of writing and even if — or especially if — one does not agree with them. The problems he raises and the questions he asks are those which most scientists do not even like to think about, let alone try to answer.

All the essays are worth reading in their own right, although two of them — a review of Jim Watson's *Double Helix* and an analysis of "Prematurity and Uniqueness in Scientific Discovery" — stand rather apart from the rest, being of borderline relevance to the central issue. Three are of outstanding interest. These are: (1) "The Dilemma of Science and Morals" which discusses the many desperate problems of how our continuously expanding knowledge should be applied practically and includes a brief but fascinating comparison between the science and technology of classical China and western scientific philosophy; (2) "Limits to the Scientific Understanding of Man", being essentially a clear-cut criticism of positivism and its later manifestations in the form of simplistic acceptance of a reality that is "built on cumulative experience" alone and is now referred to as "Scientism"; and (3) "The Decadence of Scientism" ('Decline' might have been a more appropriate word), which discusses a neo-Kantian basis for understanding and a practical morality that recognises the impossibility of true objectivity or value-free conclusions, and involves adopting what is now often referred to as a "Structuralist" and anti-beviourist approach to thinking and acting; this itself depends on analysis of "deep structures" beneath the superficialities to which alone our senses are directly responsive.

According to Stent, science, as we now know it, is on the way out. The spirit of "Faustian man" who believes in "progress" and outward striving (defined as the "will to power") is on the wane and yielding diminishing returns; it is anyway self-limiting because it seeks, and to a large extent obtains, a sense of security which quenches the thrust for more power. Faustian man, born in the ages of enlightenment of the seventeenth and eighteenth centuries and reaching maturity in the nineteenth where the solution to all problems was viewed in the context of a continuously progressive increase in knowledge and power over the outside world, is on his death bed. His spirit will be succeeded by something similar to the Polynesian-based dream of a life of ease but without grand ambitions, a rejection of the idea of "progress" and materialistic sophistications and an acceptance of the Zen principle that the recognition of subjective sensation is the only reality. The "noble savage" is not a fancy directed backwards to the distant past, but something to anticipate in the years to come. The different articles share a common theme by illustrating the problems and paradoxes which herald the end of our era. And the author, who has rightly emphasised the many analogies between science and the arts, believes that similar factors are involved in the decline of the arts which have now lost all style and discipline, become totally "freed" and will have to start again with a new impulse.

One of the first signs of the end was, according to Stent, the "beatnik" movement in Berkeley of the late 1950s and (to a later and lesser extent) the hippy creed of the 1960s. Amongst scientists themselves, the relevant factors include a growing sense of the limitations to the objectivity of our observations and conclusions and increasing estrangement between our intuitive common sense and what we have to accept as most appropriate explanations; in particular, the principle of indeterminism in physics, which is equivalent to saying that like causes do not necessarily have like effect would seem to undermine the fundamentals of scientific explanation.

Stent also refers to a phenomenon described by Mandelbrot termed "second-stage indeterminism" where probably random events, such as "noise" in an organised system, theoretically able to be eliminated by a statistical approach, nevertheless seem on analysis for limited periods, to conform to certain laws of fluctuation (for example, in coin tossing experiments). This problem is the old one of how to decide when to introduce the concept of chance and what the idea of randomness really means — a dilemma which has faced scientists for very many years. To what extent, for instance, are the structural patterns we think we see around us simply illusions, based on too superficial and prematurely completed analysis of a series of events that require an impractically long period of study for

establishing their truly random nature?

One might go further on the basis of belief in subjective reality, and ask, even in the name of science, how many of the patterns we think exist in nature are only a reflection of pre-determined patterns in our brains. But we would still have to try and decide how our brain patterns appeared in the first instance.

Associated with the rather difficult idea of "second-stage indeterminism" is that of the "spontaneous activity of the system itself" which Stent also pursues. This is really rather frightening. Are we to suppose that every system in nature has some inherently endowed freedom of action which transcends natural laws and is thus immune to scientific study? If so, it might still be argued by Mandelbrot (if not by Stent) that this is no more than what most people ascribe to the human organism in the form of intrinsic freewill, upon which we all base our ordinary lives (*and* our science) whether we believe in it or not. And so we pass on to the equally difficult concept of *self* and one's own consciousness, forever a stumbling block for most philosophers. Even the most positive of positivists would surely have to admit that to use the machine itself for studying the machine is begging a shattering question and must involve some crucial assumptions, such as that the "thing in itself" is "truly" (whatever that may mean) what we perceive it to be, which few of us would be prepared to accept.

The final paradoxical problem raised concerns the moral dilemma of what should be the principles guiding our actions in science. And it looks here rather as if Stent is more than just vaguely sympathetic to the Taoism of ancient China which teaches that man is part of an inscrutable nature and must retreat from personal striving in order to attain inner fulfilment. This, of course, is the direct opposite of Western science where nature is *not* regarded as "inscrutable", but on the contrary responds strikingly to reason and has allowed us to exploit our environment with extravagant success — at least viewed from a strictly technological angle. With Tao, "instead of Truth and Justice", he writes, "Wisdom and Harmony would [then] become the primary values". And he quotes Joseph Needham: "with their appreciation of the relativism and subtlety and immensity of the universe, [the Chinese scientists] were groping after an Einsteinian world picture without having laid the foundations for a Newtonian one". Is the implication here that, in one sense at least, the Chinese have leap-frogged Western science and could soon be way ahead on the basis of a Tao-based structure for dealing with ourselves and the world around us?

Some recent advances in brain physiology are then described, in particular the fascinating work of Hubel and Wiesel on cells of the visual cortex. This emphasises the specific selective nature of

Gunther Stent in 1949

Photo: Cold Spring Harbor Laboratory

cell response to visual stimuli, indicating that patterns we "see" are made up of an integrated synthesis of the reactions of a composite of cells programmed by the combined effect of early environment and genetic predisposition to respond only to certain restricted types of input signal. This kind of selective mechanism of response to the immediate environment applies also to other types of (biochemical) cell reaction, such as enzyme induction. It is another aspect of the type of evidence that supports a "structuralist" approach to the mechanism of understanding, being closely related to Chomsky's ideas of "deep structures" in linguistics and has taken over, during the past 30 years or so, according to Stent, from the later stages of positivism expressed, for example, in "behaviourism" which is now largely discredited. And so, it is argued, we are back — or nearly so — to the original ideas of Kant in favour of "innate, *a priori* knowledge" (that is, *not* derived from experience) which could have evolved. Darwinistically, because it was the most suitable for survival at the time. And why not? If we cannot achieve absolute understanding, why not make do with the brain mechanism presumably evolved to supply the type of "explanation" most suitable for dealing with ourselves in the world as it is — or as it was!

Stent seems inclined to use a similar neo-Kantian method for postulating an "innate ethical deep structure", present in all human beings, which he recognises as not all that far removed from Kant's "categorical imperative", defined as an ethical principle so universally applicable that it has to be accepted as a natural law . . . . so obvious that it "goes without saying" — and thereby, one suspects, is different for every individual because nobody ever seems to have to formulate it in words.

One does not have to accept all or any of the implications offered in this book in order to benefit from thinking about them. The author is not very dogmatic, anyway, and only in his predictions about the end of our era in science does he attempt to make a firm case — which is, in fact, not very convincing. We may, perhaps be at a point of inflection in the development of science, but does it really amount to the end of an era? It is indeed, strange to view his arguments about the forthcoming "age of leisure" and a rejection of material efficiency, against a background of a world where nearly 50% of the population exist near or below subsistence level and the simplest types of technological improvement could, if properly applied, ease the lot of hundreds of millions of human beings. Modern science may not reveal the truth about the Universe or solve our ethical problems, but so long as people want H-bombs, space exploration, computer technology, and so on, or simply fast transport and more plentiful forms of energy and food; then our science will be needed because it alone can deliver the goods. A philosophy of pragmatism still has a lot to be said for it, but it is not much discussed here, except as a rather unimpressive spin-off of what the author dismisses as "soft-core" scientism — a less noxious type of scientism in comparison with the "hard-core" variety which maintains that science (especially biology) provides a morality (a "moral norm") of its own based on evolution and the "natural behaviour" of animals.

This is a stimulating and thought-provoking book which is worth reading in depth by all scientists who want to consider seriously the meaning of what they are doing and who wonder why they are sometimes pressed to discuss the philosophical implications of their work and not restrict themselves to its immediate practical results or just fiddle around with an intellectually amusing toy. Our science would be in a better position to defend itself if there were more scientists who can react to Professor Stent's arguments and at least understand what it is *not;* and who can realise, with A.N. Whitehead, that despite (or along with) all its practical achievements and intellectual magnificence, we are liable "to forget how strained and paradoxical is the view of nature which it [modern science] imposes on our thoughts". □

Cell and Tissue Research

Continuation of "Zeitschrift für Zellforschung und mikroskopische Anatomie"
ISSN 0302-766X Title No. 441

Edited by W. Bargmann 1949–1978

Editors: D. S. Farner, B. Lofts, A. Oksche (Managing Editor), B. Scharrer, L. Vollrath
In Cooperation with A. Björklund, R. A. Cloney, G. v. Ehrenstein, J. Flament-Durand, G. Goldspink, T. Hökfelt, D. Szöllösi

The introduction of electron-microscopic, cytochemical, and quantitative methods is mainly responsible for the rapid progress now being made in research on the ultrastructure of cells and tissues.
Cell and Tissue Research formerly **Zeitschrift für Zellforschung und Mikroskopische Anatomie**, enables the reader to keep up with advances in these expanding fields. The journal publishes original works dealing with all aspects of descriptive and experimental cell and tissue research, including microscopic studies of human and animal morphology.
The journal is published entirely in English

Fields of Interest: Cytology, Histology, Neurohistology, Neuroendocrinology, Immunocytochemistry, Ultrastructure, Cell and Tissue Culture, Electron Microscopy, Biology, Zoology

Parallel editions in microfiche for subscribers to the journal can be purchased at one-quarter the price of the original paper edition.

Subscription Information:
1979: Vols. 196–205 (3 issues each).

All countries:
1979: DM 2780,–; plus postage and handling.
Send your order or request to: Springer-Verlag, Journal Promotion Department, P.O. Box 105280, D-6900 Heidelberg

North America:
1979: US $ 1438.50 including postage and handling.

Autumn titles from
TAYLOR & FRANCIS

SPEAKING OF SCIENCE Volume 51
Proceedings of the Royal Institution of Great Britain

A collection of evening lectures given to the Royal Institution, on a variety of topical scientific subjects, adapted for publication and written for a general readership.

0 85066 186 2 176pp 230x152mm paper £8.00

SEARCH AND THE HUMAN OBSERVER
J. N. Clare and M. A. Sinclair

Sixteen papers presented by invited experts at the 'Search and the Human Observer' seminar, Loughborough, 1979, are contained in this book. The chapters provide an up-to-date review of the psychophysical, neurophysiological, operations research, design and experimental aspects of visual research.

0 85066 193 5 196pp 230x152mm paper £8.00

FITTING THE TASK TO THE MAN
E. Grandjean

The third edition of this book, which has been considerably revised and expanded to include the latest information on work physiology and its place in the science of ergonomics. The organization of work geared to man and the optimization of man-machine systems are the central features of this work.

0 85066 191 9 380pp approx. 240x165mm cloth £14.50

DEMOGRAPHIC PATTERNS IN DEVELOPED SOCIETIES
R. W. Hiorns

Volume 19 in the Society for the Study of Human Biology Series. The chapters deal with patterns of fertility in the UK, Western Europe and the United States, sex differentials and recent trends in marriage, divorce and mortality and the fear of population decline in Europe between 1870 and 1940.

0 85066 185 4 204pp 216x139mm cloth £10.00

THE WYKEHAM SCIENCE SERIES

PARASITIC WORMS
D. W. T. Crompton and S. M. Joyner

This book is an introduction to parasitic worms and parasitism, treating the parasites as part of a dynamic relationship with their hosts, and using where possible an ecological approach to investigate the parasite in its habitat. Extensively illustrated.

0 85109 830 4 200pp approx. 216x139mm paper £5.00

sipri publications

WARFARE IN A FRAGILE WORLD
Military impact on the human environment

An examination of the extent to which warfare and other military activities contribute to a degraded environment, evaluated separately in the light of the civil use and abuse of various habitats.

0 85066 187 0 300pp approx. 230x152mm cloth £12.00 approx.

NUCLEAR ENERGY AND NUCLEAR WEAPON PROLIFERATION

This book contains the papers presented at an international symposium organized by SIPRI to examine the ways of minimizing the risks of diversion of fissionable material from civilian to military purposes, as well as the effectiveness of existing safeguards.

0 85066 184 6 460pp 230x152mm cloth £14.00

WORLD ARMAMENTS AND DISARMAMENT
SIPRI Yearbooks 1968-79 Cumulative Index

An indispensable aid for users of the ten SIPRI Yearbooks published to date. Detailed entries with thorough cross-referencing will make easily accessible every aspect of the wide range of topics covered.

0 85066 189 7 180pp approx. 230x152mm cloth £7.00 approx.

NEW JOURNAL — CALL FOR PAPERS! — NEW JOURNAL

Information Retrieval announces

The Journal of
Plankton Research
first published Spring 1979

As papers on plankton are presently scattered throughout diverse publications, this new journal will supply a focus for research results on this specialist subject.

Executive Editor:
Dr. D. H. Cushing, Ministry of Agriculture, Fisheries & Food, Directorate of Fisheries Research, Fisheries Laboratory, Lowestoft, Suffolk NR33 0HT, England

Deputy Editor:
Dr. T. Wyatt, also of above address

Production Editor:
Carolyn Roberts, Information Retrieval Ltd., 1 Falconberg Court, London W1V 5FG, England

Editorial Board:

D. J. Tranter, Sidney	R. Margalef, Barcelona
T. Bjornberg, Sao Paulo	E. D. S. Corner, Plymouth, Devon

G. Berge, Bergen	T. Vúcetic, Split
J. B. L. Matthews, Blomsterdalen	N. Della Croce, Genova
M. Omori, Paris	M. Takahashi, Tsukuba

Scope
The Journal of Plankton Research will publish papers dealing with both zoo- and phytoplankton, in marine, freshwater and brackish environments. The three main topics covered are: (1) the ecology (including model studies) of plankton, including larval and juvenile stages; (2) the physiology (including experimental results) of planktonic organisms; (3) the distribution, life histories and taxonomy of planktonic organisms.

Submission of Manuscripts
Contributions falling within the above scope are invited. Papers will not normally exceed 20 pages in length, although in exceptional cases, longer papers will be considered. Manuscripts (the original and two copies) should be submitted directly to the Executive Editor. Guidance notes for contributors may be obtained from the Production Editor.

Subscription Information
Quarterly

Subscription prices:

USA, Canada, Central & South America	US $65.00
Rest of the world (surface mail)	£35.00

Exercises in the traditional style

John Ziman

Teleology Revisited. By Ernest Nagel. Pp. 352. (Columbia University Press: New York and Guildford, UK, 1979.) $25.

THE official theology of science — as it might be enacted for example by the Council of the Royal Society if they were so wrongheaded as to ignore their own statutes forbidding such exercises — is empirical rationalism. For several centuries philosophers have been trying to elucidate and validate this creed. Of course, like any successful cultural movement, science really justifies itself by its works. But there is a species of intellectual who is not satisfied with the appearances of power, and tries to draw back the curtain hiding the machinery of science and show that it really does deserve our confidence.

In the past twenty years or so, these philosophers at the court of science have suffered a rude shock: all that they could find behind the fearful mask of the Wonderful Wizard was a little old man, gentle and wise but with no hot line to the Absolute. Critics such as Karl Popper, Norwood Russell Hanson and Thomas Kuhn have effectively demolished the claims of the scientific method as a means of arriving at certain truth.

For the older generation, this movement of Reformation has been an unhappy experience. Should they trendily embrace the latest doctrines, or should they stick with familiar beliefs that they cannot honestly discard? Professor Nagel retains "the outlook of an unreconstructed empirical rationalist", which he defends with characteristic wisdom and tolerant precision of thought and expression in this collection of essays. Although these were published independently over a period of more than 40 years, and are not artfully melded into a continuous narrative, they are remarkably consistent and coherent in style and content. If their outlook would be stigmatised as old-fashioned by the Younger Turks, it is not reactionary, and is very far from outmoded as a practical faith for the working scientist.

In fact, there are truths here that must be reckoned with. In the earlier chapters he brings to a halt the sloppier elements in Popper's fallibilist attacks on the traditional position. It may not be possible to define a general distinction between theory statements and observation statements, so that all science is in principle conjecture. But that does not mean that scientists are talking nonsense when they make such distinctions in the course of their research. Nagel acknowledges Popper's contributions in other respects, but repulses what he aptly calls the "Mephistophelian view of science . . . according to which to suppose even for a moment that any problem is really solved is to lose one's soul". And he annihilates Paul Feyerabend's irregulars after their wildly undisciplined charge to the cry "anything goes".

On the other flank, he repudiates false allies. The critique of Carnap's attempt to construct a logic of inductive reasoning is polite and detailed — but devastating. The mathematical theory of statistical inference has, I think, made some technical progress in recent years, but no intellectual structure can be safely founded on a symbol that is supposed to stand for the number of primitive predicates that might hypothetically be postulated concerning some body of evidence. To put it more succinctly than Nagel, it all seems to be a question of knowing how many beans make five. Empirical facts do not support theories by any device of strict logic.

Nevertheless, within these limits, his position is very open to attack from quite another quarter. That is to say, his genuine concern for the realities of the research process is applied solely to the arguments by which scientific knowledge is justified in the public literature. He admits that "assured knowledge in science is the product of a community of thinkers, each of whom is required by the tacit traditions of his group to be unsparing in his criticisms and evaluations of the cognitive claims presented to him" (page 13). But he does not seem to realise the corollary — that the scientific community may be (usually quite reasonably) persuaded to accept a cognitive claim on evidence that is much less watertight logically than philosophers would like. Nagel quite ignores the element of what Michael Polanyi called "tacit knowledge" in the assessment of research, and makes no reference to the social relations of the scientific community where this non-logical expertise is valued and shared.

In this light, the earliest essays in this book (dating from the 1930s) are of peculiar interest and significance. They show in detail, through the history of algebra and geometry, the pressure that can be exerted on an empirical science by the demand for logical consistency and completeness, The paradoxical appearance of imaginary numbers and imaginary points gradually drove nineteenth-century mathematicians into the modern stance, where each branch of pure mathematics is regarded simply as a system of relations derived conventionally from a prescribed set of axioms, without reference to any particular reality. In every stage of this process, extra power is gained by the increased generality of the results; but the outcome can only be correctly stated in Bertrand Russell's dictum that the pure mathematician does not know what he is talking about nor whether what he says is true.

Empirical rationalists have always been strong supporters of mathematical theory in science. They are very conscious of the value of reliably rigorous logical passages in scientific statements. But the more we purify a mathematical formalism, the more we come to realise that it is only the *medium* of communication between scientists and does not of itself constitute a *message* about the natural world. The empirical element in a scientific statement can only be expressed intelligibly in natural language, whose categories are inevitably somewhat vague. It is a pity that Nagel's remarks on this point were written before Stephan Körner had demonstrated its deadly significance for any strong logic of scientific justification.

What is also missing is a realisation of the dependence of scientific communication on non-logical human capabilities such as pattern recognition. It is true that a geometrical theorem can only be proved generally by the juxtaposition of abstract symbols for logical relations: but for most practical purposes the old Euclidean method, with its reference to diagrams, is suffiently convincing. From experimental high energy physics to sociobiology, every branch of the natural sciences is knit together by communications conveying diagrammatic inferences that cannot be interpreted by any known logical formalism but which are perfectly intelligible to another human being.

In the real world, it is the consensus that can eventually be reached by systematic intersubjective communications that defines our standards of objectivity and rationality. This applies at every level, from the everyday world of tables and chairs to the hidden world of quarks and neutrinos. It also applies to metascientific discourse on such questions as the relationship between theory and observation, or between cause and function. The point is that words like these are thematic rather than categorical. Like a picture, or a diagram, or a familiar model, they can convey very important ideas which cannot be defined, or paraphrased briefly, or precisely, or entirely unambiguously. They can only be understood in the light of experience, not of formal logic. In the final essay, Professor Nagel struggles to define the concept of teleological explication in biology, and effectively admits at the end that it was an impossible task.

Nevertheless, such strenuous exercises in the traditional style remain highly instructive for the research scientist, who must surely continue to believe, along with Professor Nagel, that "the logical methods of the modern natural sciences are the most effective instruments men have yet devised for acquiring reliable knowledge of the world and for distinguishing warranted

claims to such knowledge from those that are not". This (as the Council of the Royal Society would correctly perceive) is the faith upon which science is built, and the disciplinary code, at platoon, regimental, and divisional level, which binds it together in its war on ignorance and error. And yet there are perhaps occasions when such simple loyalties fail us, and the direction of the Army itself has to be called into question. □

John Ziman is Professor of Physics at the University of Bristol, UK.

Updated science policy almanac

Austen Albu

Science and Government Report International Almanac, 1978-1979. Edited by D.S. Greenberg and A.D. Norman. Pp. 368. (Science and Government Report, Inc., P.O. Box 6226, 3736 Kanawha St NW, Washington DC, 20015, 1979.) $54.

It can be assumed that any study published today on government policy and organisation for science will be more concerned with technology than with pure science. Whether in captialist or communist countries this represents a victory for those pre-War marxist scientists who advocated planned support for science applied to utilitarian ends. The new edition of this valuable report, covering a period when economic difficulties restrained the expediture of most countries on R&D, makes it clear that pure science plays a decreasing role in government support policies compared with applied science and technology. Even Israel, which claims high support for basic research, based on its traditional approach to learning, has seen a significant increase in the proportion of applied research and development in the past few years. Although they do not all follow the same pattern, these national reports give an invaluable picture of recent developments in public policy and attitudes, and in changes in organisation for scientific advice and the carrying out of policy.

All governments support R&D, but the degree to which they do so financially and the organisations they use for the purpose vary a good deal. Britain and France seem to be among those countries with the most centralised structures among the advanced industrial nations. Even the USSR, if one forgets the overarching position of the Party, seems to have a wider range of institutions, although they are constantly changing. The growing emphasis on R&D to improve industrial production seems to have led to some decline in the prestige of the Academy of Sciences in face of the State Committee for Science and Technology.

In the United States the growth of anxiety in official circles about the country's apparent diminishing capacity for industrial innovation was one reason for President Carter's proposals to raise the rate of growth of funds for R&D, especially basic research. Congress, however, had rather different ideas and kept the 1979 expenditure to a total only fractionally more than that of 1978. One of the results of the increased involvement of governments in science and technology is the politicising of the decision-making process. In that most democratic of federations, Switzerland, the voters in referenda have displayed hostility to expansion of the universities and to subsidies to industry for R&D. This may be of little importance as Switzerland has the highest per capita rate of R&D expenditure in the world; 80% of it by private industry. Apart from wishing to curtail government expenditure, some voters in most countries are becoming increasingly interested in 'ethical' aspects of science or questions of the effects of technology on 'life style'. The main targets at present are nuclear energy and recombinant DNA. The former is an obvious embarassment for governments struggling with energy problems and no doubt adds to the growing part energy plays in national research programmes. Popular interest in the supposed dangers of recombinant DNA has been greatest in the USA and UK; in most other countries it has only attracted the attention of scientists and administrators.

The richer countries are concerned with problems of health research, both its changing nature and its accelerating cost. In the USA the Secretary of the Department of Health, Education and Welfare addressed scientists last year on the need to devise "health research principles" to be used for planning a "rolling" five year budget for the Department's programmes. The Federal Republic of Germany has published a programme of Promoting Research in the Service of Health, 1978-1981, of which an extremely interesting excerpt from the English translation is reproduced. It includes an examination of the difficulties of health research and a detailed list of fields in which greater R&D efforts would seem to be necessary.

So far the Trades Union in most countries have not shown much sustained interest in the problems involved in the results of scientific research. Only in the Scandinavian countries have permanent bodies been established by the Unions to keep them under survey. In France the scientific associations acted as pressure groups during the Presidential election of 1979 in which science policy played a prominent part.

Some rather unexpected figures in the output of scientist are revealed. In Sweden there was a fall in the output of Doctorates in the Natural Sciences between 1970 and 1976 from 461 to 172. In Britain, during the period of university growth in the 1960s scientific subjects got left behind, so that the "swing away from science" in the 1970's seems by contrast fairly modest. On the other hand engineering, at least in numbers, kept pace with university expansion. This, however, does not take account of a rapidly growing number of foreign students. The most unbalanced figures come from India which, in 1977, produced 140,600 graduates in the Natural Sciences and 15,000 in Engineering; bringing the total number of science graduates in the population to 1,182,272 of whom 16.1% were unemployed and of engineers to 251,860 of whom 2.4% were unemployed.

The most significant differences between nations lie in the ratio of government to private industry financed R&D and the proportion of military expediture. This may provide at least a partial explanation for the decline of British industrial performance. In Britain, France and the USA goverment provides more than half the nation's R&D funds; in Germany, Italy, the Netherlands, Sweden and Canada between 40 and 50%. In Japan the figure is about 30%, but Japan has the third largest R&D programme in the world. What is more significant is the fact that in the UK annd the USA roughly 50% of government R&D funds are spent on military programmes against a EEC average of 23%, a German figure of 12 and Japanese of 2. In all the major Western countries except the UK the share of government R&D spent on military programmes declined during the 1970s. In the UK it increased between 1970 and 1976 from 41 to 48%. If research expenditure is to be reduced these figures indicate where the possiblities of cuts should at least be scrutinised. On the other hand it seems that R&D activity by industry has been declining in the UK while that of the UK's main competitors has been rising; a matter which must be of concern to a government committed to reversing the decline of British industrial competitiveness.

This is the second year of publication of this important almanac. As an essential source of reference for scientific administrators, politicians and students of the subject it is to be hoped that it has now become firmly established in the rather overgrown forest of journals dealing with science policy. □

New myths for old

Jon Beckwith

From Genesis to Genocide: The Meaning of Human Nature and the Power of Behavior Control. By S.L. Chorover. Pp. 238. (MIT Press: Cambridge, Massachusetts, and London, 1979.) £9.35; $14.

IN recent years a number of controversies have erupted over theories and practice in the biological and medical sciences. These debates include the subjects of genetics, race and IQ; the XYY male; sociobiology; psychosurgery; behavioural control practices in prisons; and the giving of drugs to school children said to be suffering from minimal brain dysfunction. A number of books have already appeared which deal with most of these issues from a critical perspective, including notably Kamin's *The Science and Politics of IQ* (Halsted: New York, 1974), Schrag and Divoky's *The Myth of the Hyperactive Child* (Dell: New York, 1975) and Ann Arbor Science for the People's *Biology as a Social Weapon* (Burgess: Minneapolis, 1977). However, nowhere, to my knowledge, has there been any extensive attempt to draw connections between all of these controversies. Now, Stephan Chorover, in this remarkably concise piece of writing (208 pages of text), for the first time, places all of these issues in a common framework and describes them in terms of a long historical tradition which preceded them.

Chorover, a psychologist at MIT, with a long-standing interest in abuses in psychology and psychiatry, unites what might seem to be disparate subjects by analysing them in terms of "meaning and power" in the realm of behaviour control. By these terms he refers on the one hand, to those mythologies, religious doctrines or scientific theories, which have served to structure people's view of their place in the world. ". . . what people believe about the essential nature of human beings has a powerful influence upon social expectations. Such beliefs tend to shape the ways in which people in a given social context are treated, and these in turn, significantly influence how they behave." Thus, ". . . ideas about human nature . . . deserve to be regarded as powerful instruments of behaviour control in their own right". "Power", on the other hand, refers to the power of certain groups in a society to apply these theories in practical ways for social control. The extreme example is, of course, genocide practiced by the Nazis based on biological theories of racial inferiority and superiority.

The book abounds with other historical and contemporary examples. Perhaps two of these will give some feeling for the analysis. In 1851, Dr Samuel Cartwright, a respected Louisiana physician, published a report commissioned by the Louisiana Medical Association purporting to explain among other things why there were runaway slaves. The roots of this problem, according to the doctor, lay in a disease of the mind which he termed "drapetomania", "the insane desire to wander away from home". Various punishments of the runaway slave could then be considered merely as medical treatments.

In a contemporary case study, Chorover describes in detail the story of "Thomas R." a portion of whose brain was removed during the heyday of psychosurgery in the late 1960s. Among other frightening stories associated with this case, he reports that the surgeons concluded that Thomas R. was psychotic partly on the basis that he was convinced that his wife was "carrying on with a neighbour". However, after the surgery took place his wife filed for divorce and eventually married that same neighbour. Thomas R., himself, has been socially non-functional since the operation and has spent much of his time in mental institutions.

Chorover, in reviewing the long history of what are essentially biological determinist theories, goes back to what he refers to as "Plato's lie". This term refers to the theory presented in *The Republic* that different people are born with different qualities of metals (gold, silver or brass and iron) mingled into their bodies, and that the metals in turn determine what status in society individuals will occupy. According to Plato (through Socrates) such a lie is necessary to justify existing social stratification. To Chorover "the basic texture of human nature mythology remains everywhere and always the same and . . . Plato's myth of the metals may be considered a prototype for todays myths".

It must be asked, of course, whether modern science has provided a much more solid basis for theories of human nature than earlier religions and mythologies. Chorover's answer is a clear no. He points to arguments used in the nineteenth and early twentieth centuries in the name of science (eugenics, phrenology, craniology, and so on) which we now recognise as totally without foundation. As a curious means of self-justification in the face of their critics, practitioners of these sciences have always likened themselves to Galileo, persecuted for trying to present the truth. Of course, Galileo, as Chorover points out, was attacked because his theories challenged the established order of things, whereas the makers of what Chorover generally calls sociobiological theories have, for the most part, provided rationales for existing social arrangements. He sees contemporary sociobiological theories as having no more solid scientific

new books from
Blackwell

The Restoration of Land
the Ecology and Reclamation of Derelict and Degraded Land
Studies in Ecology Volume 6 by A. D. Bradshaw and M. J. Chadwick. December 1979. 314 pages, 193 illustrations. About £12.50
This book deals with the problems of derelict land on a world-wide scale. It shows how the problems can be solved most effectively by a proper scientific understanding of the ecological factors that effect plant growth, but it takes a practical viewpoint and will be invaluable for the engineer and landscape architect as well as for the scientist.

Developmental Biology of Prokaryotes
Studies in Microbiology Volume 1, edited by M. Parish. 1979. 310 pages, 93 illustrations. £19.00
Prokaryotes are bacterial and related organisms. Their developmental biology comprises morphogenesis, differentiation and pattern formation or development. The book discusses these processes with reference to the bacterial cell cycle, sporulation, morphogenesis in arthrobacters, life cycles of streptomycetes, bdellovibrios, cyanobacteria and myxobacteria.

Plant Health
the Scientific Basis for Administrative Control of Plant Diseases and Pests
Edited by D. L. Ebbels and J. E. King. December 1979. 334 pages, 21 illustrations. About £16.00

Population Dynamics
20th Symposium of the British Ecological Society, edited by R. M. Anderson, B.D. Turner and L.R. Taylor. December 1979. 448 pages, 144 illustrations. £20.00

Decomposition in Terrestrial Environments
Studies in Ecology Volume 5 by M. J. Swift, O. W. Heal and J. M. Anderson. 1979. 392 pages, 112 illustrations. £22.50

Demography and Evolution in Plant Populations
Botanical Monographs Volume 15, edited by O. T. Solbrig. December 1979. 240 pages, 36 illustrations. About £15.00

basis then their predecessors and laments the "inability or unwillingness of scientists to examine the social preconceptions inherent in the organization and conduct of their own work."

Although Chorover has done an impressive job of drawing the connections between his different topics, there are times when the attempt to unite all of the issues seems strained, as represented, for instance, by the title of one chapter "Genocide: The Apotheosis of Behavior Control". Further, although the role of sociobiological theories in justifying an inferior status for women is mentioned at several points, this subject deserves much more extensive treatment, particularly in the light of the recent resurgence of such ideas. These defects, however, do not seriously detract from the unusual service that this well-documented and well-referenced book performs for biologists, social scientists, psychologists and the public at large. For, to this reader, one is not equipped to evaluate these issues as they appear without an analysis which considers the social context and historical background to particular questions at the interface of science and society. □

Instantaneous expertise

Thomas H. Jukes

Malignant Neglect. By the Environmental Defense Fund and Robert H. Boyle. Pp275. (Alfred A. Knopf: New York, 1979.) $10.

THE dust-jacket of this book modestly states that it "is based upon the enormous resources and scientific knowledge and authority of the Environmental Defense Fund (EDF), the nation's leading force in the field of environmental health". One author is a journalist, one a biochemist, one a science associate, and the qualifications of the other four are not listed.

A normal metabolite, acetaldehyde, is called a "known or suspected carcinogen" (page 105), and ammonia a "toxic organic vapor". The familiar litany is recited that no level of a carinogen is insignificant, and that the latent period for development of cancer is 5-40 years (page 6). Actually, the risk and length of time required for appearance of symptoms are both dose-related.

A graph (page 21) compares increase in cancer mortality rate for 1940-1975 (uncorrected for smoking, page 214) with increases in production of plastics and other organic chemicals. Compared with plastics, similar increases have occurred in skateboards, tomato production and pocket calculators.

Chapter 3 is about polychlorobiphenyls (PCBs). There is no lack of public information on this topic. But what is the record of the EDF on PCBs? Jensen's publication in 1966 (page 64) attracted wide attention to contamination by PCBs. The EDF virtually ignored PCBs and campaigned against DDT, so that in 1969, the "end of the ocean" by 1979 was predicted as a result of the arrest of photosynthesis in marine algae by DDT. However, Harvey *et al.* in 1973 reported that PCBs were present in surface water of the North Atlantic Ocean at about 20 p.p.10^{12}, and the level of DDT was less than 1 p.p.10^{12} Scott found in 1975 that DDT, 100 p.p.m. of diet, had no effect on hatchability and shell thickness in laying hens, as compared with lethal effects produced by PCBs at 20 p.p.m. PCBs were dumped promiscuously, because they were never subjected to the justifiably careful regulations that govern insecticides.

Page 102: "Driving through New Jersey... On U.S. 1, ... one begins to detect a pungent odor, like that of rotting friut. At first the odor is faint, but as the car swings into the New Jersey Turnpike, the smell grows stronger... Closing the windows does no good; the stench pours through the vents. The sky become visibly darker, like the twilight or an eclipse of the sun. At last, ... the source comes into view. It is perhaps the largest complex of oil refineries and petrochemical plants in existence... At night the flares atop the refineries produce an eerie light that transforms the scene into something from Dante's *Inferno*... Fourteen thousand poeple die each year from cancer in New Jersey".

On September 24, 1979, I drove south from Newark on the New Jersey Turnpike. I passed through the "refinery complex" at 6.45 p.m. There was no odour, there were no flares, and the only visible emission from the refinery was a few wisps of steam. To the west, there was a brilliantly clear sunset in which a range of hills, 30 miles away, was sharply etched against the sky.

Alarming statements are made about diethylstilboestrol (DES) used in meat production, and it is said (pages 149-151 and 219) to be detected in 1-2% of table meat and in pancreas. It has been detected only in liver, and only 0.6% of 8,293 beef livers sampled contained more than 0.5 p.p.b. The DES intake from meat is less than 0.001% of the equivalent daily oestrogen production by a nubile woman. Page 151 infers erroneoulsy that nitrofurans are antibiotics, and states "Even minute residues of antibiotics in meat and poultry can sensitize people and cause allergic reactions, such as rashes and shock, when one of these antibiotics is medically administered". I know of no evidence for this. Insufficient emphasis is given to the carcinogenic role of alcohol.

Arsenic and chromium, listed as

carcinogens, are nutritionally essential trace minerals, which is not mentioned. Either there is a threshold below which such substances are not carcinogenic, or there is no threshold, and therefore life is carcinogenic, but we cannot deny *both* of these possibilities. But the authors repeatedly emphasise that there is no safe dose of any carcinogen, and, on page 211, they say "'Life' is not carcinogenic". I disagree. First, there must be a threshold for certain carcinogenic stimuli (such as iodine deficiency in rats). Second, life can be carcinoginic because mutations accumulate in DNA during ageing, including mistakes in DNA replication and those caused by environmental mutagens.

Appendix A says that caffeine "may cause miscarriages or birth defects". Such a statement is pointless without being quantitative and is also irresponsible and sensational. The final chapter is "The Solution to the Problem", emphasising pages 224-232) "Personal Involvement in the Regulatory Process".

Leading experts in the field of environmental cancer are far less dogmatic than are the EDF sextet. John Higginson concludes (*Science*, **205**, 1363; 1979), that the manner in which people live — diets, dress, sexual and child bearing patterns, and especially tobacco and alcohol consumption — account for the great variations in cancer rates in different countries, and may be far more important than chemical pollutants. He reports that cancer patterns within Europe show no correlations with industrialisation. He says... "people would love to be able to prove that cancer is due to pollution or the general environment. It would be so easy to be able to say let us regulate everything to zero exposure and we have no more cancer. The concept is so beautiful that it will overwhelm a mass of facts to the contrary". □

Thomas H. Jukes is a Professor in Residence in the Department of Biophysics and Medical Physics, and a Lecturer in Nutritian Sciences at the University of California at Berkeley.

Potency of interferon

D. C. Burke

The Interferon System. By W. E. Stewart. Pp.421. (Springer: Wien and New York, 1979.) DM98; $53.90.

THIS book is a comprehensive review of the entire interferon literature, and fills a considerable gap. The last single-author book on interferon appeared in 1969 and the last multi-author book in 1973. Since then a number of specialist reviews have appeared, but no-one until now has had the courage and energy to tackle a survey of the field single-handed. The author is to be congratulated on a fine achievement, and the book will be greatly used.

As the author points out, interferon has received considerable recent publicity in both the scientific and popular literature as a potentially useful antiviral and antitumour agent. Its potential as an antiviral agent has indeed been obvious ever since its discovery by Isaacs and Lindenmann in 1957, but it has been slow to realise it. In retrospect, this is partly because quite inadequate amounts of interferon were available for the early trials, and partly because we did not choose the most suitable infections for treatment.

Attention has now swung away from treatment of respiratory infections to such life threatening conditions as chronic active hepatitis and viral infections of immunosuppressed or immunodeficient patients. Here useful and encouraging trials are taking place. It is, however, the potential use of interferon as an anti-tumour agent that has attracted most recent attention, for, stimulated by a careful ongoing trial against osteogenic sarcoma in Sweden, there have been several well-publicised reports of its activity against human cancer in the USA. In addition, interferon has emerged as a cellular modulatory factor, affecting the growth of cells, the immune system and the growth of tumours; and the mechanism by which it is produced is being investigated as a model for gene derepression in eukaryotes.

The book is therefore timely. Interferon research has continued apace and we greatly need a good critical summary. The book will be invaluable for those who are starting research in the area, but also for those who, like the reviewer, have been in the field a long time but who cannot remember who did what and when. The book has a complete coverage discussing topics as disparate as the structure of double-stranded RNAs, the genetics of the interferon system, the pharmacokinetics of interferon, and its role in normal recovery from virus infection, in addition to the trials as an antiumour and antiviral agent. The bibliography contains nearly 2500 references and the author has compiled 18 tables, many of which summarise information which has not previously been drawn together — for example, a compilation of the properties of type II interferon and a seven-page table of the cross-species activities of interferons.

However, the book is more than a compilation, for the author does not hesitate to comment, often constructively. There are, for example, interesting discussions of the different hypotheses which have been advanced to explain the mechanism of virus induction of interferon, of the mechanism of superinduction, and of the various schemes for interferon purification.

Unhappily, in spite of the wide usefulness the book will undoubtedly have, the book is flawed by personal animus against a few scientists, and by occasional lapses into slangy diction. Cells do not "quit" making interferon, and sentences like "Studies on the mechanisms controlling the transcription and translation of interferons will likely soon enable better artificial regulation of these mechanisms, to provide sufficient interferon messenger RNA to allow its retrocopy into prokaryotic cells from which clones interferon can become truly abundant" make one gasp. □

D. C. Burke is Professor of Biological Sciences at the University of Warwick, Coventry, UK. He has worked on interferon since April, 1957, starting to collaborate with the late Dr Alick Isaacs and Professor Jean Lindenmann a month or two after the initial discovery.

Elements of cloning

Marie A. DiBerardino

Cloning: A Biologist Reports. By R.G. McKinnell. Pp. 130. (University of Minnesota Press: Minneapolis, 1979.) $8.95.

PROFESSOR MCKINNELL terminates his book with the following three sentences in the epilogue: "Cloning is one of many experimental procedures that provide information that may help in solving problems such as cancer and ageing. That is the why of cloning. And to assist people in understanding that "why — i.e., the rationale of cloning — I have written this book". The author has accomplished his objective. He is a research biologist who has carried out nuclear transplantation studies (one form of cloning) directed towards understanding normal cell differentiation, cancer, immunobiology and ageing. Few scientists possess both the authoritative background and literary talent to communicate accurately the relevance of bench-work research to its future potential for solving biomedical problems. McKinnell, however, manages to convey the significance of this basic research to the non-scientist.

McKinnell begins his book by correcting erroneous and inflamnatory statements about cloning and points out that the cloning of plants has been in practice for over 4000 years and has served to enrich man with beauty and food. This process is achieved by means of asexual reproduction resulting in a genetic replicate of the parent, whereas sexual reproduction involves the combination of genes from two parents and thus produces an individual containing a diversity of genetic traits.

The author then embarks on a description of classical animal studies carried out during the late nineteenth and early twentieth centuries that laid the ground-work for the amphibian cloning experiments. During this period there occurred a fusion of the disciplines of genetics, embryology and cytology; and the central problem that occupied these early scientists was the theory of nuclear equivalence. They sought to determine whether the diverse specialised cells of an organism retain the same set of genes as the nucleus of the fertilised egg. The earliest scientists recognised the stability of the differentiated state, that is, liver remains liver even if a person lives beyond ninety years, as pointed out by McKinnell. To explain this phenomenon, a theory of genetic differences among the progeny of the zygote nuleus was proposed by Weismann to account for the origin of cell diversity and stability. However, this proposal was refuted at least for nuclei from the earliest stages of development by the primitive cloning experiments of Loeb in the sea urchin and later of Spemann in the salamander. Finally, in 1952 "a fantastical experiment" termed and proposed by Spemann, was accomplished by Briggs and King. They sought to extend the primitive cloning experiments and transplanted a living nucleus from a cell from a frog blastula embryo, a day old, into a frog egg whose own nucleus had been removed surgically. The blastula embryo contained thousands of cells all derived from a zygote nucleus, but these blastula nuclei were still capable of promoting eggs to develop into normal larvae and eventually in later studies into normal frogs, demonstrating that the donor nuclei contained a set of genes equivalent to the zygote nucleus. This prototype experiment has been repeated many times in various amphibian species throughout the world, and it is now well established that many nuclei from early embryonic stages are *totipotent*. The theory of nuclear equivalence is still the central problem of developmental genetics today. The cloning studies have been most extensively carried out in two amphibian forms — the leopard frog, *Rana pipiens*, and the South African frog, *Xenopus laevis*. Cloning experiments have shown that during the course of embryogenesis, transplanted nuclei become progressively restricted in their ability to promote normal development of the eggs; and so far no nucleus of an *adult* cell has programmed an egg to develop normally. Despite this, a most extraordinary result does occur when nuclei from adult cells are cloned. A small percentage of eggs develops through embryogenesis to early larval stages and contain all the cell types and tissues of a larva, indicating that an extensive gene complement is still present and functional. Similarly, frog nuclei from adult kidney tumours when transplanted to eggs also lead to the formation of larvae. This subject, an area in which the author has made important research contributions, is discussed at some length. He points out that the formerly held pessimistic view of the irreversibility of cancer has been alleviated by these and other experiments. Thus, although important strides have been made in studying problems of normal cell differentiation and cancer, much more needs to be done in the future. McKinnell proposes: "If more were known about cancer-cell genetic material and about regulating its differentiated state, there would be the rational hope that a cancer chemotherapeutic agent could be devised that would regulate differentiation of these malignant cells".

Although amphibian cloning has been the most extensively studied among multicellular organisms, there has also been some work done on insects and fish. However, attempts at mammalian cloning have so far not been successful. But McKinnell points out that many of the techniques are available and the expectation that the remaining ones will be solved is encouraging. Cloning of farm animals may have agricultural advantages — for example, one could select for outstanding milk production, quality of wool, disease resistance, and so on; and this approach would be extremely faster than selective breeding for genetic traits.

Finally, McKinnell reviews some of the concepts of human cloning theorised by science-fiction writers, philosophers, theologians and lawyers. He addresses himself as a biologist and expert cloner to the social, ethical and biological problems inherent in their suggestions. Among his various refutations he emphasises that cloning may result in genetic replicates but not carbon copies, a widely misunderstood point. He also points out that species are successful due to the diversity of genes available through sexual reproduction, and so cloning is not a sound reproductive method.

McKinnell has performed an important service for both scientists and non-scientists in his well balanced and critical review of cloning, and at an appropriate time when both groups need an accurate account of the applications of nuclear transplantation studies to the biomedical sciences, in order to evaluate the erroneous and exaggerated notions of cloning that have been perpetrated upon the public. This book will be especially invaluable to non-specialists. A series of superb illustrations, together with the clarity and simplicity of prose, will permit the non-specialist to understand the basic elements of cloning and its biomedical implications.

Marie A. DiBerardino is Professor of Anatomy at the Medical College of Pennsylvania, Philadelphia. Dr DiBerardino began her nuclear transplantation studies with the originators of cloning (Briggs and King) during the 1950s.

Dahlem Workshop Reports

Dahlem Workshops derive their name from the section of the City of West Berlin where they were founded. Four times annually top experts from the international scientific community are invited to spend a week in Berlin in order to do hard and creative work: They discuss an interdisciplinary subject of high topicality until an authentic and well balanced report on the state of the art can be given.

These unique reports are subsequently publicized as ***Dahlem Workshop Reports.***

Besides taking stock of contemporary knowledge, every Dahlem Workshop is expected to review new concepts and new experimental techniques. Here the task of the group is to recommend future directions of research, which are both promising and urgently needed in order to fill gaps of knowledge. Again, these recommendations constitute part of the Dahlem Workshop Reports.

Each Dahlem Workshop Report is published within six months after the end of the conference. In this way the international community of scientists can benefit from the results at the earliest possible point in time.

From the two series ***"Physical and Chemical Sciences Research Reports"*** and ***"Life Sciences Research Reports"*** 13 titles are available altogether. For more and detailed information please use the attached Info-Coupon.

Spherical Models

MAGNUS J. WENNINGER

This beautifully illustrated and charming book from the author of the widely praised *Polyhedron Models* explains how to make models of spherical polyhedra from simple materials, using simple mathematics, a ruler and a compass. The author gives detailed instructions and illustrates these with photographs, drawings and computer graphics. This book will be enjoyed by all those interested in recreational mathematics and by students and teachers of art, design, architecture and mathematics.

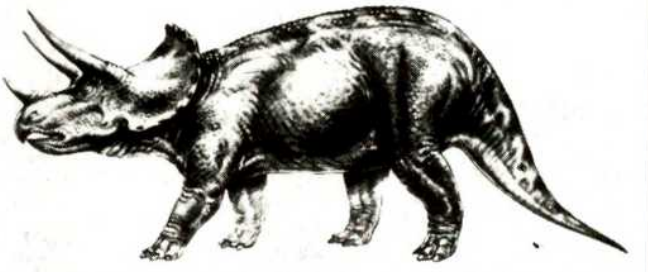
The Messier Album

JOHN H. MALLAS and EVERED KREIMER
Edited by OWEN GINGERICH

Based on the authors' highly praised series of articles in *Sky and Telescope* this volume is a blend of expert astronomical observations, superb pictures and historical lore that will be welcomed by amateur and professional astronomers and beginning observers. The book recalls the life and works of Charles Messier and other eighteenth-century astronomers, and illustrates the most spectacular sights in his list with a 31-page gallery of superb colour photographs.

'It is a handsome volume, well produced, and good to dip into . . . .' David Allen in *Sky and Telescope*

228 x 152 mm 248 pp. 31 colour subjects, 100 line diagrams
0 521 23015 2 **£6.95 net**



What Little I Remember

OTTO FRISCH

In this delightful autobiography the late Otto Frisch relates some of the most exciting developments of modern physics, including his discovery of nuclear fission, a term he himself coined. Professor Frisch describes vividly how he witnessed the unravelling of the double helix, the making of the first atomic bomb and the birth of radioastronomy. His entertaining anecdotes of the many great scientists he met during his lifetime create the background for his pen portraits and the many photographs included in the text.

'This is a happy book, from which the author's personality and his enjoyment of physics, of music, of life emerges clearly.' Rudolf Peierls in *Nature*

216 x 138 mm 240 pp. 47 half-tones, 6 line figures
0 521 22297 4 **£9.50 net**

Dinosaurs and their Living Relatives

BRITISH MUSEUM (Natural History)

This book is being produced to coincide with a major new permanent exhibition at the British Museum (Natural History). The exhibition explores the relationships between dinosaurs (animals that died out 65 million years ago) and other animals, both living and extinct, notably birds and crocodiles. Most of the material in the exhibition is being specially adapted for the book, and the lively and informal approach is retained throughout. The book is extensively illustrated with beautiful colour pictures, and there is a useful glossary as well as notes on the lifestyles of many of the dinosaurs.

216 x 216 mm c. 72 pp. numerous illustrations

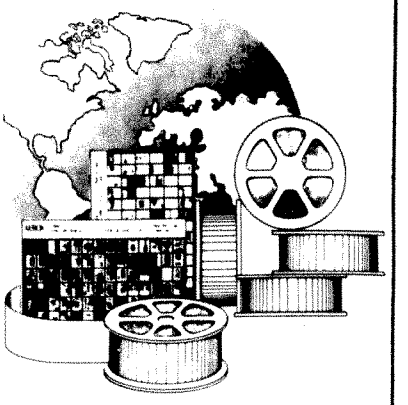
Cytogenetics stages its own revival

Susumu Ohno

Human and Mammalian Cytogenetics: An Historical Perspective. By T.C. Hsu. Pp. 186. (Springer: New York, Heidelberg and Berlin, 1979.) Paperback $13.20; DM24.

IN 1959, Jerome Lejeune of Paris discovered the trisomy of chromosome 21 in those unfortunate individuals afflicted with the congenital syndrome then known as mongolian idiocy, now called Down's. With simultaneous discoveries by several British groups of the X0 sex chromosome constitution as the cause of Turner's syndrome in sterile women as well as of the XXY constitution in sterile men with Klineferter's syndrome, 1959 heralded the birth of human cytogenetics. Although the scale was obviously at least an order of magnitude smaller than that of the discovery of the DNA double helix in 1953, these discoveries, nonetheless, generated immense interest. In the heady day of an emerging molecular biology that was sure to become the core of the new biology, who would have thought that the venerable chromosome cytology of a distinctively pre-War vintage would stage its own revival? Furthermore, in so delicate a creature as *Homo sapiens*, who would have thought so gross a genetic imbalance as the trisomy of a whole chromosome could give rise to live births?

In spite of its belated birth, at least by 10 years in my reckoning, the revived old soldier did not immediately fade away. On the contrary, subsequent events made a long success story out of human and attendant mammalian cytogenetics. Soon, Lyonisation (inactivation) of one of the female's two X-chromosomes was established as the dosage compensation mechanism unique to mammals, and the discovery of evolutionary conservation, as opposed to innovation, of mammalian linkage groups in general, and the X-linkage group in particular, dramatically altered our view of the nature of natural selection. Somatic genetics based on cell fusion to produce interspecific somatic cell hybrids became the precocious child of human and mammalian cytogenetics. The technique of *in situ* hybridisation proved useful in localising prepeated DNA sequences on individual chromosomes. When an apparent senescence was about to start, Caspersson came to the rescue with the innovation of a chromosome banding technique.



Now that senior members of the group involved in these initial excitements have passed or are approaching retirement age, one might expect a series of memoirs of those events. Professor T.C. Hsu of Houston opens up with a noteworthy salvo giving his own breezy and gossippy account. Of course, Rudolph Virchow's dictum *Omne cellule a cellule* applies equally well to scientific discoveries. The well publicised discoveries of 1959 were preceded by earlier ones; for example, the development of tissue culture techniques, the use of hypotonic pretreatments (T.C.'s own discovery) and colchicine, and the correct description of the normal human karyotype by J.H. Tijo and A. Levan that rectified earlier misunderstandings. Earlier still, a few outstanding investigators such as Sajiro Makino of Sapporo and Robert Matthey of Lausanne had accomplished a great deal in mammalian cytogentics without any of the above noted modern conveniences. In T.C.'s portrayal of those participants of the drama, one finds a number of witty gems; for example his accounts of Sajiro Makino and Kurt Benirschke.

It should be pointed out, however, that three participants of the same event are likely to give three entirely different versions of it. The fact is that the excitement of 1959 was essentially a European affair to which those of us across the Atlantic played second fiddle. Therefore, I await with great anticipation equally witty, but entirely different versions from some senior members of the European group.

Who should read T.C's memoir? I should say everybody, particularly those researchers of the younger generation — as recommended by M.J.D. White in his foreword, but for a different reason. I see one lamentable defect in the otherwise bright young generation brought up with the television screen. Because of their apparent abhorrence of printed words, the papers that they never read are unashamedly quoted and misunderstood and the writing style of scientific manuscripts is becoming entirely monotonous, as though they had been turned out by the same old computer. Julius Ceasar wrote his *Commentaries* and Augustus his *res gestae*. While nobody seems to care about them, almost everybody seems to know Claudius' gossippy memoir *à la* Robert Graves. If books like T.C.'s can rekindle the joy of reading in the heart of younger scientists, Professor Hsu should feel very proud. □

Core of controversy over biohazards

Sheldon Krimsky

The Recombinant DNA Debate. Edited by D.A. Jackson and S.P. Stitch. Pp.385. (Prentice-Hall International: Englewood Cliffs, New Jersey, and Hemel Hempstead, UK, 1979.) £14.55.

THE controversy of the past eight years over the regulation of recombinant DNA techniques has left in its wake some unusual and vexing policy issues. For the non-molecular biologist peering through the key-hole at the disputants, listening to a genetic vernacular that could pass as extra-terrestrial noise, the debate gives the appearance of a family feud. And it might have remained just that way were it not for the scientists who alerted the public to the potential hazards of their own work. Given the public's concern about this area of research and development, scientists may view similar acts of social responsibility as a danger to their disciplinary autonomy.

The principal target population affected by controls and regulation is a group of scientists engaged in basic research. Consequently, predominant expertise resides with a major interest group. The experts who are called upon to guide us through a safe technology path and on whom we must depend for objectivity can hardly qualify as impartial. Paradoxically, without them there could be no risk assessment.

The recombinant DNA episode holds many riches for science-watchers. It has stimulated discussion on a wide range of problems from public participation in the formation of science policy to the future prospects for human genetic engineering. In their edited volume *The Recombinant DNA Debate* David A. Jackson and Stephen P. Stich provide a series of essays that reach the central core of the scientific controversy over biohazards and, in addition, examine some of the moral and legal issues involved in the regulation of scientific inquiry. Stich, a philosopher, was on the faculty of the University of Michigan during the period the volume was in preparation. David Jackson, a University of Michigan microbiologist, was senior author of the first published paper on recombinant DNA techniques. Jackson also helped establish Genex, a US firm set up to develop commercial uses for recombinant DNA techniques.

The book, consisting of seventeen papers written between 1975 and 1977, is divided into three sections: Part I introduces the non-specialist to the techniques of genetic engineering; Part II examines the risks and benefits from various sides of the controversy; and Part III considers legal, social and philosophical issues. Most of the scientific contributors have also been principal actors in the debate (A.M. Chakrabarty, Roy Curtiss III, Bernard D. Davis, Joshua Lederberg, Robert Sinsheimer and George Wald). For this review I shall limit my comments to selected essays.

A.M. Chakrabarty reviews the areas in which recombinant DNA techniques may prove fruitful. These include drug, chemical and fuel manufacturing, crop improvement, and the treatment of genetic disorders. It is too early to judge whether or not Chakrabarty's optimism that recombinant DNA, by revolutionising the manufacture of biologically active proteins, "would make them available in large quantities at modest cost and would contribute significantly to the betterment of human health and welfare.". It is perhaps a symptom of the snail's pace of technology assessment that neither in this volume nor in the vast literature on this subject does their exist an analagous technical discussion of areas of potential misapplication or willful misuse of recombinant DNA technology.

Roy Curtiss III describes his construction of a strain of *E.coli* with twenty-four specific mutations designed to render it safe for molecular cloning. While initially an integral part of a strategy for biological containment, the skillfully engineered strain of *E.coli* (Chi 1776) may soon be irrelevant for the vast majority of experiments in the US. Recently, the Recombinant DNA Advisory Committee of the National Institutes of Health (NIH) voted to exempt most experiments from the NIH guidelines when ordinary laboratory strains of *E.coli* K12 are used. Little incentive remains for scientists to continue using the highly sensitive Curtiss strain despite its widely acclaimed safeguards.

Papers outlining the potential dangers of gene-splicing are contributed by Robert Sinsheimer, George Wald, and the recombinant DNA study group of Science for the People. Both Sinsheimer and Wald implore their colleagues to consider the long-term ecological consequences of this new-found power to rearrange genetic substance across widely divergent species. Their emphasis is on the possibility of unexpected events or "evolutionary booby-traps", in contrast to specific scenarios of danger.

As a counterpart to the DNA critics, there are contributions by Bernard D. Davis and Rolf Freter focusing on imagined, as opposed to real, dangers of the research. Davis invokes Darwinian evolutionary principles to argue that Nature abhors new pathogens. In his view, biological competition and natural selection operate in tandem to inhibit the establishment of novel pathogens in the ecosystem. Freter reviews the experimental data relevant to the question of whether *E.coli* K12 can be transformed into an epidemic pathogen. The evidence, he concludes, suggests that we cannot produce an *E.coli* superpathogen by recombinant DNA techniques. Nevertheless, he emphasises the importance of weakened hosts in gene-splicing experiments for the safety of laboratory personnel and recommends the use of *E.coli* strains incapable of growing in germ-free mice (a property of Chi 1776).

Two philosophical papers appear in Section III. Stephen Stich examines several types of moral reasoning voiced during the most active period of the debate. He challenges the view that scientific research should be curtailed if it can lead to the discovery of knowledge that might be disastrously misused. He believes that such a principle, if consistently applied, would paralyse all research: "It is hard to think of an area of scientific research that *could* not lead to the discovery of potentially dangerous knowledge." While Stich gives serious attention to the use of probability estimates of biohazards, he neglects to apply similar reasoning to the application of research programmes. The potential for misuse of science is not distributed uniformly among all research enterprises; consequently, some may warrant greater social control than others.

Carl Cohen, in his essay "On the Dangers of Inquiry and the Burden of Proof", wields a philosophical scalpel to the critics of recombinant DNA research. He skillfully dissects their arguments, exposing lack of rigour and their weak analogical reasoning and use of criticism, to which no response is possible ("heavy question arguments"). Cohen's reconnaissance of the terrain of criticism is limited to the most radical critics. Moreover he says nothing about the faulty reasoning and emotional responses of proponents of laissez-faire science. There, too, one finds arguments built on conjectures and quasi-scientific findings.

This is the first collection of papers on the recombinant DNA debate by a major publisher for a non-technical audience that addresses scientific, philosophical and policy issues. The essays are generally of high quality. They centre around the controversy in the US up to 1977. Since that time new issues have surfaced including the patenting of novel life forms, the rise of commercial interest in recombinant DNA techniques, the health of workers in large scale fermentation plants, and the disposal of by-products in production.

The weakness of this collection is in its failure to cover the political and sociological context of the debate. With the slight exception of an essay by sociologist Max Heirich on how the funding of science affects decision-making about science, there is no treatment of the key determinants that shaped DNA policy in the US. Factors of interest are: the

REIDEL'S AUTUMN LIST

Dynamics of the Magnetosphere

S.-I. AKASOFU (ed.)
Contains papers by experimenters, analysts, and theorists on major substorm problems with special emphasis on theoretical interpretations in terms of plasma processes.
662 pp. Cloth Dfl. 130,– / US $ 68.50
ISBN 90-277-1052-X

An Introduction to Nuclear Astrophysics

J. AUDOUZE, S. VAULCLAIR
A complete and simple introduction to the most modern aspects of nuclear astrophysics. Describes the formation of chemical elements which constitute the Universe.
about 185 pp. Cloth Dfl. 75,– / US $ 39.50
ISBN 90-277-1012-0
Paper Dfl. 40,– / US $ 19.95
ISBN 90-277-1053-8

The Large Scale Characteristics of the Galaxy

W. B. BURTON (ed.)
Papers based on I.A.U. Symposium No. 84. Emphasis is placed on the relationship between recent work on other galaxies and the large-scale study of our own galaxy.
about 620 pp. Cloth Dfl. 140,– / US $ 73.50
ISBN 90-277-1029-5
Paper Dfl. 70,– / US $ 36.85
ISBN 90-277-1030-9

Quantum Theory of Chemical Reactions

Volume I: Collision Theory, Reaction Path, Static Indices
R. DAUDEL, A. PULLMAN, L. SALEM, A. VEILLARD (eds.)
Discusses the fundamental problems which occur when studying a gas phase reaction or a reaction for which the solvent effect is not taken into account.
about 247 pp. Cloth Dfl. 65,– / US $ 34.20
ISBN 90-277-1047-3

Techniques and Applications of Fast Reactions in Solution

W. J. GETTINS, E. WYN-JONES (eds.)
Proceedings of a NATO conference on new applications of chemical relaxation spectrometry and other fast reaction methods in solution.
621 pp. Cloth Dfl. 110,– / US $ 57.90
ISBN 90-277-1022-8

Palladium Catalyzed Oxidation of Hydrocarbons

P. HENRY
Reviews the sub-field of palladium as well as synthetic and mechanistic aspects of the oxidation of organic compounds by palladium salts.
about 420 pp. Cloth Dfl. 125,–/US $ 65.00
ISBN 90-277-0986-6

Language of the Stars

Z. KOPAL
Develops and describes a new branch of celestial cryptography and comprises the methods of analysis of the light changes (signals) of stars known as eclipsing variables.
about 285 pp. Cloth Dfl. 120,–/US $ 63.00
ISBN 90-277-1001-5
Paper Dfl. 55,– / US $ 28.95
ISBN 90-277-1044-9

Introduction to Advanced Astrophysics

V. KOURGANOFF
Introduces radiative transfer and internal structure of normal stars, white dwarfs, neutron stars, pulsars, Newton's Law, binary systems, galactic X-ray sources, cosmology, elementary theory, and basic observational data.
about 490 pp. Cloth Dfl. 135,–/US $ 71.05
ISBN 90-277-1002-3
Paper Dfl. 55,– / US $ 28.45
ISBN 90-277-1003-1

Advances in the Preparation and Properties of Stereoregular Polymers

R. W. LENZ, F. CIARDELLI (eds.)
Proceedings of a NATO meeting investigating the design, synthesis, characterization, and application of stereoregular or structurally-ordered polymers.
about 400 pp. Cloth Dfl. 85,– / US $ 44.75
ISBN 90-277-1055-4

Intercalated Layered Materials

F. A. LÉVY (ed.)
The first book ever to be devoted entirely to intercalated compounds. Serves as an essential reference and research manual.
about 575 pp. Cloth Dfl. 150,– / US $ 78.00
ISBN 90-277-0967-X

2nd E.C. Photovoltaic Solar Energy Conference

R. VAN OVERSTRAETEN, W. PALZ (eds.)
Discusses the ever-increasing applications of solar cells and reviews the recent developments in the field. It forms a unique reference work and serves as a guide to national R & D activities.
1228 pp. Cloth Dfl. 135,– / US $ 71.05
ISBN 90-277-1021-X

Wave Instabilities in Space Plasmas

P. J. PALMADESSO, K. PAPADOPOULOS (eds.)
Reviews and presents new trends in a number of problems connected with nonlinear effects of waves in space. Intended primarily for the ionospheric, magnetospheric, and plasma physicist.
316 pp. Cloth Dfl. 75,– / US $ 39.50
ISBN 90-277-1028-7

Catalysis in Chemistry and Biochemistry Theory and Experiment

B. PULLMAN (ed.)
Proceedings on the 1979 Jerusalem Symposium on quantum chemistry and biochemistry. Reviews the present status of catalysis in chemistry and biochemistry from theoretical and experimental points of view.
about 385 pp. Cloth Dfl. 85,– / US $ 45.00
ISBN 90-277-1039-2

Optically Active Polymers

E. SÉLÉGNY (ed.)
Investigates the synthetic or natural chiral macromolecules; ORD or CD techniques; and studies conformational or interactional problems.
about 425 pp. Cloth Dfl. 135,– / US $ 71.05
ISBN 90-277-0904-1

Refractional Influences in Astrometry and Geodesy

E. TENGSTROM, G. TELEKI (eds.)
Papers based on I.A.U. Symposium No. 89. It summarizes the results of recent research such as new extra-atmospheric observing techniques, and research in refraction on the vertical, and lateral longitudinal effects.
about 430 pp. Cloth Dfl. 95,– / US $ 50.00
ISBN 90-277-1037-6
Paper Dfl. 50,– / US $ 26.50

From Reviews of the First Edition

'... an excellent little volume ... will be invaluable to those who wish to gain access to exciting new developments ...'

Nature

'... admirably clear and up to date ... an excellent introduction to a most intriguing development in human genetics.'

Journal of Medical Genetics

'... entirely praiseworthy ... highly recommended for almost anyone interested in HLA from undergraduate students to advanced workers in the field who will find it a convenient source of key references.'

Annals of Human Biology

This volume is the second, revised edition of a work highly acclaimed for its success in surveying the most important basic facts concerning the HLA system. In concise fashion, the authors introduce the reader to the historical background of HLA, genetic aspects, and methods of typing. Of particular interest are sections focused on areas of clinical medicine where HLA studies have improved understanding of etiologically obscure diseases. The original references, praised for their completeness, have been supplemented with over 100 additional citations current through 1978.

Fields of Interest Anatomy, Histology, Embryology; Immunology; Biology for Physicians; Genetics, Immunobiology, Serology, Transplantation

Main Headings

– Note on Nomenclature
– Introduction
– Historical Background
– Components of the HLA System
– Linkage Relationships of HLA
– Geographical Variation
– Homologous Systems in Animals
– Notes on the Biochemistry of HLA Antigens
– Biology of the HLA System
– HLA in Clinical Medicine
– HLA in Paternity Testing and Twin Classification
– Appendix: Methodology

effectiveness of the scientific lobby; the commercial ties of scientists in the recombinant DNA field; the control of the risk assessment process; the ability of scientists to contain the issues to laboratory biohazards; the role of environmental groups; and the politics of the Recombinant DNA Advisory Committee. We shall await another collection of papers to bring the issues up to date and address these critical factors. □

Sheldon Krimsky is Acting Director of the Program in Urban Social and Environmental Policy at Tufts Unversity, Medford, Massachusetts.

Synthetic biology

Richard Roblin

A Double Image of the Double Helix: The Recombinant DNA Debate. By Clifford Grobstein. Pp. 177. (Freeman: San Francisco and Reading, UK, 1979.) Hardback £6.90; $11; paperback £3.50; $5.95.

THE tone of books about the recombinant DNA policy debate has both reflected and fueled the intensity of public concern. As the debate grew heated during 1976–78, books by journalists and science-writers vividly detailed the early history of the controversy, and discussed possible biohazards. In the quieter atmosphere of 1979, Clifford Grobstein has contributed a balanced, analytical view of the American sector of the recombinant DNA landscape which emphasises the science and public policy issues thrown up by the turmoil. In doing so, he has written an excellent primer for the next stage of discussion about recombinant DNA policy issues.

Grobstein's book will be read with profit by a variety of readers. Here, interested members of the public will find an outline of the relevant science, a history of the controversy, and thought-provoking discussions of exploration, risk and research regulation. Scientists should find interesting Grobstein's interpretations of the social and political context of their research, even though they may not like the world which he describes. Bureaucrats and legislators should ponder Grobstein's comments on the incompleteness and instability of current public policy on recombinant DNA research. In Grobstein's opinion, failure to extend application of the NIH Recombinant DNA Research Guidelines to industrial as well as academic research risks undercutting their effectiveness.

One of the major sections of the book deals with the issues surrounding regulation of basic research. Grobstein finds such regulation generally distasteful, and articulates several requirements for sound regulation of research. He views continued research and expansion of human knowledge as "essential to the public interest", and would restrict these only when "there is compelling evidence of clear and present danger." However reassuringly familiar this criterion sounds to American ears, how would it apply in the recombinant DNA case? The conjectural nature of recombinant DNA biohazards remains the central intellectual dilemma of recombinant DNA policy. Except for intentionally malevolent applications, there never was, and may never be, compelling evidence of clear and present danger in the use of recombinant DNA techniques. What policy to follow given this uncertainty remains the central issue of the recombinant DNA debate. Does this mean that Grobstein believes the guidelines approach and the concommitant public and legislative furore to be an example of unsound regulation? He doesn't say, and I believe he would have made his book better if he had been more specific in this and several other places.

One thorny problem associated with the recombinant DNA debate is the role of the public in policy formation. If there are conjectured risks to public well-being because of the use of recombinant DNA techniques, then should the public have a say in how these techniques are to be used? Grobstein points out the tendency to apply criteria and procedures developed for regulation of human experimentation to recombinant DNA research. This analogy led some to suggest that appropriate policy for recombinant DNA research required something like a public 'informed consent' before proceeding with widespread use of the technique. Grobstein raises, but does not directly answer, the question of whether this extension of the principles of risk–benefit calculation and informed consent is appropriate for research in general (or recombinant DNA in particular). My own feelings are that these criteria are not appropriate where risks are conjectural, because meaningful risk–benefit estimations cannot be made. In addition, why single out the area of recombinant DNA research, when public "informed consent" has not been seriously urged in other research situations (for example, deepspace exploration) where risks could also be conjectured?

Inevitably, in an area as fast moving as recombinant DNA research, the pace of new discoveries outstrips the rate at which books can be conceived, written and published about them. Thus, Grobstein mentions only in a footnote the recently discovery that the DNA sequences which code for several eukaryotic viral and cellular proteins are not all adjacent to one another as they are in bacterial DNA. The discovery of 'split genes' and RNA splicing in higher eukaryotic cells, and the lack of evidence for RNA splicing mechanisms of comparable specificity in *E. coli*, have led many scientists to conclude that split eukaryotic viral and cellular genes will not be correctly translated into functional proteins in *E. coli*. If many eukaryotic genes are split and cannot produce functional proteins in *E. coli*, then the chance of producing pathogenic *E. coli* through 'shotgun' cloning of eukaryotic DNA segments is reduced still further. These arguments were partly responsible for the considerable reduction in containment for such cloning experiments in the December 1978 revision of the NIH Guidelines. It is unfortunate that Grobstein was unable to include the impact of this new information in his discussion of potential risks in recombinant DNA research.

Grobstein ends his book with a suggestion that a presidential study commission be appointed to work toward a comprehensive assessment of issues generated by the recombinant DNA debate. He feels that this would create a needed arena "in which all issues can be examined and which gives full access to all interested parties and experts". However, since Grobstein's book was written, there have been significant changes in both the content and administration of American recombinant DNA policy. Estimates of the possible risks of recombinant DNA experimentation have dropped further. Accordingly, containment requirements for several types of experiments have been reduced, and significant supervisory authority over recombinant DNA experiments has been delegated to local Institutional Biosafety Committees. The NIH Recombinant DNA Advisory Committee (RAC) has been enlarged to 25 members, thus expanding its expertise and diversifying it politically. Meetings of the RAC have become a national forum for debating and voting to recommend changes in the NIH Guidelines, the chief ingredient in current American recombinant DNA research policy. RAC procedures, which provide for prior publication of proposals to be discussed and publicly accessible meetings, have opened a permanent channel for public input into decision-making on recombinant DNA research policy. In addition, the major scientific and procedural objections of critics like Sinsheimer, Wald and King have either been accommodated or been found to be generally unpersuasive. In the light of these recent developments, one wonders whether Grobstein would continue to advocate a presidential study commission.

Given the current trend, we are at the beginning of a period in which the NIH Guidelines will be partially or completely

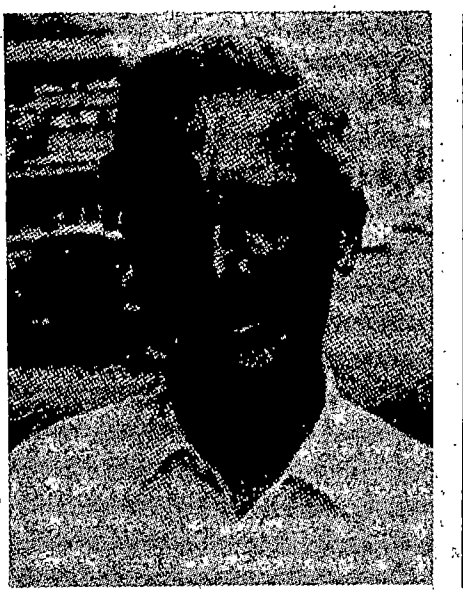
dismantled. Some scientists believe that it will be possible to stuff the genie of regulation of recombinant DNA research back into the bottle. If so, what kind of a legacy will the recombinant DNA debate leave? Perhaps it is too early to clearly assess this question, but the following thoughts come to mind. The development and evolution of guidelines for recombinant DNA research provides a case-study in innovative formation of a policy to cope with uncertainties generated by a major expansion in human knowledge and power. Early discussion of the possibilities in public, a continuation of cautious research coupled with risk-assessment studies, and built-in mechanisms for modifying regulations in the light of new knowledge may prove to be useful principles in analogous future situations. In addition, the recombinant DNA debate has conveyed to a wide audience the vast potential of the 'synthetic biology' opened up by recombinant DNA techniques. Thoughtful consideration of the ends to which this potential is being and could be applied should commence, as concern over potential biohazards diminishes. □

Richard Roblin was a member of the National Academy of Sciences Committee on Recombinant DNA Molecules and the organising committee for the 1975 Asilomar Conference on Recombinant DNA Molecules. He is now Head of the Molecular Biology of Tumor Cells Group, Cancer Biology Program, Frederick Cancer Research Center, Frederick, Maryland.

Drives and action patterns

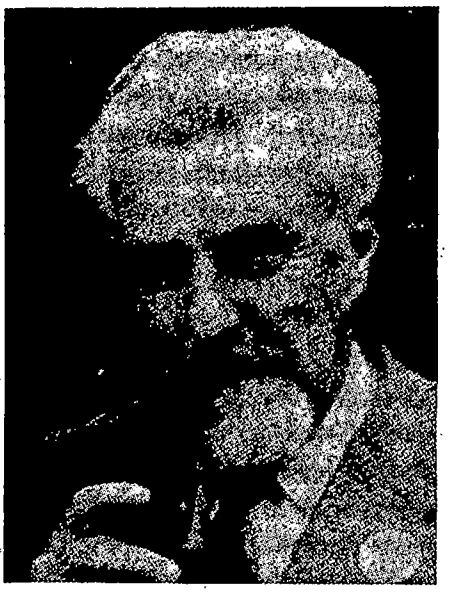
John R. Krebs

The Origins and Rise of Ethology: The Science of the Natural Behaviour of Animals. By W. H. Thorpe. Pp. 174. (Heinemann Educational: London, UK; Praeger/Holt, Rhinehart and Winston/CBS: New York, 1979.) £5.90.



THIS book is an extended version of the first Niko Tinbergen lecture, given by Professor Thorpe to the Association for the Study of Animal Behaviour in 1974. He describes how ethology started, what it was like in the middle of the twentieth century and what it is about today. The middle section of the book, which is full of anecdotes and personal recollections of Professor Thorpe, is to my mind the best.

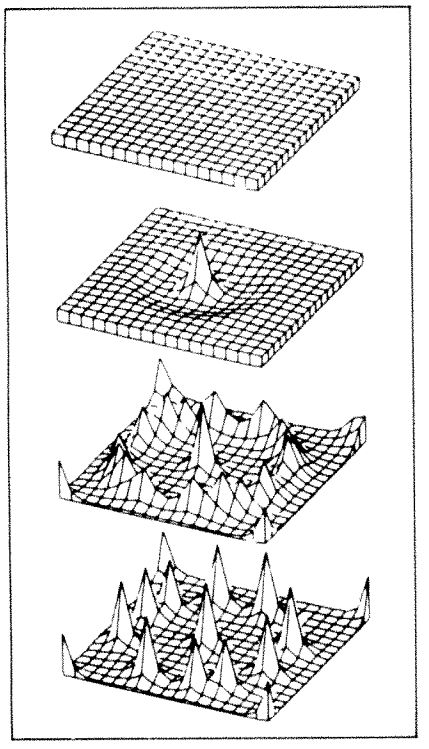
The early history of ethology is traced by Thorpe to John Ray, the seventeenth century British naturalist who, among many other things, did experiments on clutch size in birds. The subject in its present day sense (the naturalistic study of animal behaviour; not the "science of character-formation" as in the term used by J.S. Mill) emerged in France in the eighteenth and early nineteenth centuries through the writings of C.G. Leroy, J.B. Lamarck and E. Geoffroy-Saint-Hilaire. (Some readers may be amused to know that Leroy was gamekeeper of the area in France called Marly — virtually the same name as that given to the wood near Oxford in which R.A. Hinde carried out his thesis research nearly 200 years later.) Although Britain had a strong traditon of country naturalists in the eighteenth and nineteenth centuries, Thorpe rightly emphasises D. Spalding as the key British figure in the early development of ethology. Spalding pioneered experimental studies of behaviour development and had a great impact on Lloyd Morgan, who was influential in espousing a scientific, reductionist approach to the study of animal behaviour. Among early American students of behaviour, Thorpe mentions particularly the contributions of Whitman, Craig, Lashley and Wheeler; perhaps he should also have included W.C. Allee whose book *The Social Life of Animals* foreshadowed much that is current in ethological thinking.



From this straightforward historical account, Thorpe moves to the period with which he is familiar from personal experience. In the 1930s and 1940s ethology became firmly established as a discipline distinct from other approaches to the study of behaviour, mainly through the work of Lorenz and Tinbergen. The account of this period is very revealing to those who have seen only only the later years of the era of these great men. Today, Lorenz's theories are viewed as somewhat old-fashioned and naive, but as Thorpe stresses "The very fact that Lorenz's early papers now appear so outdated is a tribute to their effectiveness . . . It is the impetus which they gave to experimental work which has, in a sense, rendered them so quickly out of date, although they are still of course extremely well worth reading".

According to Thorpe, the central problem facing ethologists in the 1930s was to elucidate the nature of instinctive behaviour. Although it was widely recognised that animals perform complicated "goal oriented" sequences of behaviour, such as nest-building and courting, without any particular training, there was no conceptual framework within which to analyse and dissect these instinctive behaviours. Lorenz provided the framework in a series of papers published in the decade 1931-41. Instincts were viewed as being made up of simple stereotyped, inborn movements (fixed action patterns) linked together by more flexible and modifiable goal oriented behaviour (appetitive behaviour). Both of these were thought to be driven by "specific drives" (physiological mechanisms). Usually the fixed action patterns were released by a specific stimulus (releaser) and they were consummatory in the sense of dissipating the specific drive for that appetitive behaviour and fixed action pattern sequence. Internal drive was considered to then gradually build up until a fixed action pattern could discharge it again. If no suitable stimulus appeared, the action might go off "in a vacuum". Professor Thorpe stresses that this theoretical framework was valuable bacause it immediately led people to investigate in detail the nature of instinctive behaviour. For example, physiological and endocrinological studies of drives, perceptual studies of releasers, and genetic studies of fixed action patterns were set up to test Lorenz's ideas.

While providing a lucid account of Lorenzian theory, Professor Thorpe also tells us many anecdotes from the immediate post-War years. Stories are told of how Lorenz nearly went to Cambridge



Niko Tinbergen and Konrad Lorenz in Cambridge, 1959

Synergetics

– an exciting new field of interdisciplinary research

H. HAKEN

Synergetics

An Introduction

Nonequilibrium Phase Transitions and Self-Organization in Physics, Chemistry and Biology

2nd enlarged edition. 1978. 152 figures, 4 tables. XII, 355 pages
Cloth DM 66,—; US $36.30 ISBN 3-540-08866-0

"Synergetics, according to Professor Haken, is the study of how component subsystems can interact to produce structure and coherent motion on a macroscopic scale. In fact it is a theory of selforganisation with applications not only in physics and chemistry but also in biology and sociology. In this book an introduction is given to the basic physical ideas and mathematical methods to be used. The text is imaginatively written and well illustrated by an amazing variety of examples drawn from such diverse fields as laser physics, fluid dynamics, mechanical engineering, chemical reactions, ecology and morphogenesis. . . Professor Haken is to be congratulated in producing such a readable introduction to a subject still in its infancy." *Physics Bulletin*

Announcing Two New Journals

Teratogenesis, Carcinogenesis, and Mutagenesis

Volume I, 1980, four issues

In the last several years, there has been a great increase in scientific and social interest in teratogenic, mutagenic, and carcinogenic agents in the environment. Recognizing that the biological activity of such toxic agents is frequently similar, **Teratogenesis, Carcinogenesis, and Mutagenesis** has been founded to serve as a forum for the most advanced research in these crucially important, related areas.

The journal will publish reports of original research concerned with the detection, classification, and evaluation of environmental agents that induce or promote teratogenesis, carcinogenesis, and mutagenesis; in vitro and in vivo analyses of the mechanisms of action of these toxic substances; and new techniques aiding this basic research work.

Teratogenesis, Carcinogenesis, and Mutagenesis is intended for investigators in such fields as toxicology, genetics, microbiology, biochemistry, radiation biology, and basic cancer research.

Bioelectromagnetics

Volume I, 1980, four issues

This new journal will be devoted to reports of theoretical and experimental studies of the effects of electromagnetic environments, ranging from constant fields to visible light, on biological systems. Clinical studies discussing the uses of electromagnetic fields will also be included.

Bioelectromagnetics will consider for publication articles reporting complete findings of original research as well as concise critical reviews of current research developments. The major areas of interest to the journal are: responses of biological systems to electromagnetic environments; mechanisms of interaction of electromagnetic fields with biological processes, and models of these processes; absorption and distribution of electromagnetic energy within biological systems; and diagnostic and therapeutic uses of electromagnetic fields.

instead of to the Max Planck Institute; how Lorenz and Tinbergen quacked like ducks to put off two predatory women; and how Thorpe himself was asked to present a paper of "about two hours" when he turned up at the First International Ethological Conference! It would be nice if this part of the book were expanded into a full volume at a later date.

The last chapter, on the present position of ethological concepts and research, is also fascinating from an historical viewpoint. It illustrates how the same events can be seen in a totally different light by observers from two different generations. In Thorpe's view, ethology today still works within the Lorenzian framework, and the questions asked still deal with fixed action patterns, drive, displacement activities, releasers, and so on. The details have changed very much, but the conceptual armoury is still the same. To an ethologist trained a generation later, the view is that ethology (in particular British and American ethology) underwent a purge in the 1950s and early 1960s, mainly due to the masterly critiques of R.A. Hinde; in this much of the earlier Lorenzian theorising was rejected and replaced with a hard-headed, reductionist approach. This created a spartan atmosphere in which theorising was definitely out, and hard data in. Then the early 1970s saw a flowering of new theoretical ideas and new questions about behaviour, this time linking ethology with population genetics and evolution. Perhaps there will be a new purge in the 1980s.

Neither of these contrasting views about present-day ethology can be said to be right or wrong: they emphasise that in spite of our attempts to be objective about the behaviour of animals, the interpretation of our own history is very much subjective. □

Selected genetics

M. J. Lawrence

Understanding Genetics. By E.B. Ford. Pp. 201. (Faber and Faber: London, 1979.) £7.25.

PROFESSOR FORD tells us in the preface that this book is an attempt to meet the needs of those who, whether they be men of general education or scholars in other fields of learning, wish to know something of the theoretical aspects of genetics. This is a laudable, though ambitious, objective, for if such an attempt is to succeed, the author will have to possess an unusually wide and deep knowledge of the subject, so as to be able to give both an adequate coverage of it and to deal with open questions in a fair and unbiased way. To what extent does Professor Ford's new book meet this requirement?

The book contains eight chapters which deal with the Principles of Genetics; Sex; Evolution; Polymorphism and Mimicry; Industrial Pollution; Genetics in the Countryside and Garden; Individual Variation in Man; and Genetics and Human Societies. The contents of the book reveal that Professor Ford's coverage of the subject is far from complete, for he deals only with some aspects of classical, human and what he has called ecological genetics. There is nothing about molecular or microbial genetics, despite the fact that these are now the most actively researched areas of the science and are, moreover, ones which raise problems of great interest to the layman. This omission, furthermore, is no mere oversight, because we are told that the structure of DNA is "much beyond what is appropriate for a book of this kind" (page 30). This is surely a serious error of judgement. The reader will look in vain, therefore, for enlightenment on why, for example, there has been much public debate on the subject of genetic engineering. For this they would have to look elsewhere.

Those who are familiar with Professor Ford's style will know what to expect from this book; nor will they be disappointed, for here again we find his characteristic, enthusiastic and authoritative treatment of the subjects with which he deals and also a number of amusing and illuminating anecdotes, including one about how to plan for a scientific camp. Indeed, the book seems to be derived from two of Professor Ford's previous books, *Ecological Genetics* and *Genetics for Medical Students*, and is therefore something of an intellectual biography of his work. Those who are familiar with this work, however, will also know that there is by no means general agreement on some of the matters that are discussed. For example, apart from the obvious exception of sickle-cell anaemia, there is almost no evidence to justify the confident statement on page 151 that "heterozygous advantage is the usual method for maintaining polymorphic variation", though it is, of course, possible that some polymorphisms are maintained in this way. Then again, we do not know "that it is usual for" selective advantages "to reach 20 or 30 per cent, often much more" (page 69). The layman, however, will be unaware of these biases and hence is likely to be seriously misled when he goes on, as Professor Ford hopes he will, to pursue his interest in genetics in other works.

There are, unfortunately, other errors of emphasis and, indeed, of fact in the book. For example, we are told on page 155 that "it would be highly *suspicious* [my italics] if a pair of blue- or grey-eyed parents had a child with dark-brown eyes". While such an outcome would be unusual, such cases have occurred in circumstances where the paternity of the child was beyond reasonable doubt. Then again, I know of no evidence to justify the statement on page 74, concerning the pairing of homologous chromosomes during the first division of meiosis that "allelic attraction must be stronger when the pairs are identical (homozygous) than when they are dissimilar (heterozygous)". Is it really the case that Man is more variable than other species (page 13) and that among our races, the Japanese are "much the less diversified" (page 172)? There is a particularly misleading error in the simple numerical example on page 28 which Professor Ford uses to explain how the order of genes along a chromosome may be determined from the results of a three-point backcross (his ACB should be BAC). On page 57 we are told that if "we keep organisms in a strictly constant condition in the laboratory, all their variation *is* [my italics] genetic" (would that this were true!). The simple method for the detection of heterozygous advantage given on page 107 is unsatisfactory because the χ^2 in question can be significant in the absence of this type of selection. Lastly, on page 116, where Professor Ford writes, about self-incompatibility in those species in which this is determined by a single, multi-allelic gene and control of the pollen reaction is gametophytic, that: "If both the male and female plants possess, for instance, *S2* and *S2* (one carried by the pollen, the other possessed by the stigma) fertilisation fails". This statement is highly misleading because it is true if and only if the comment in parenthesis is ignored (if the latter were correct the cross would be compatible). There are a number of other errors in the book, including some concerning page and author references; and the way in which some of the subject material is dealt with in the last two chapters of the book made this reader uneasy.

Reviewing this book has been a painful task, because I, like many of my colleagues in the field of ecological and population genetics, owe Professor Ford a great debt; he is one of the pioneers of the subject and has made many distinguished contributions to it. But in view of the stated aims of the book, we have a wider duty to those people for whom it is intended. With this in mind, the book cannot be recommended to the layman. □

Illuminating astronomy

Owen Gingerich

Man's View of the Universe: A Pictorial History. By G.E. Tauber. Pp. 352. (Crown: New York, 1979.) $19.95.

TAUBER'S elucidation of "evolving concepts of the universe from ancient times to today's space probes" belongs to the genre of history of astronomy in the service of popularisation. He thus joins the class whose predecessors range from Camille Flammarion to Patrick Moore and Fred Hoyle.

An historical approach is particularly felicitous for astronomy, with its long and nearly continuous development. It has the advantage of starting with the simplest observations and theories, which can introduce the novice to the sky as it still appears. The story then leads through the drama and pathos of Galileo, to the puzzling and curious genius of Newton, and finally in a modern climax to Einstein and relativity. Tauber exploits the anecdotal and the picturesque to leaven what is essentially a popular textbook, and in so doing produces a guide to modern astronomy far more readable than the typical elementary textbook. He is obviously most at home with relativity and with cosmology, and there his presentation is outstanding. But the subtitle, *A Pictorial History*, promises us more than a mere textbook, and alas from either the pictorial or historical viewpoint the book is a considerable disappointment.

There are, to be sure, hundreds of illustrations, which in effect form a separate and parallel account, unreferenced and almost completely unlinked with the running text. Some of them are fresh and attractive, such as the pair of portraits of Wilhelm IV of Hesse and his wife, the Foucault pendulum in the Pantheon, or Robert Goddard beside an early liquid rocket. However, many are commonplace and often poorly reproduced; a significant proportion of the illustrations are line diagrams, which emphasise the textbook aspects to the detriment of the historical qualities.

Consider, for instance, the section on Newton: the best of the illustrations is a fine manuscript drawing of Newton's telescope, and there are halftones of Newton, Woolsthorpe, a modern painting of Newton with his prism, plus muddy views of Huygens and conic sections. But these are overwhelmed by a score of diagrams representing everything from the graph of an inverse square law, a hopelessly wrong scheme of recombining coloured light with a second prism, a redrawing of Newton's famous (and incorrect) diagram on free fall from his letter to Hooke, precession, tides, and so on. The Newtonian section epitomises the pictorial problems of the entire work: squeezed and uninviting layouts, erratic quality of reproduction, and uninspired typography. It would be heartless to dwell further on these inadequacies, for which the publisher is probably more to blame than the author.

Several pictures are erroneously captioned or credited. The widely copied traveller poking his head through the vault of the heavens to see the celestial gearwork beyond is here reproduced as a sixteenth-century woodcut, although it is now definitely established as late nineteenth-century art nouveau, probably from the hand of Camille Flammarion. It is hard to believe that the photograph purporting to be the Magellanic Clouds on page 241 really shows those objects. On page 36 there is "an artist's view (date unknown) of Thales' universe", in the public domain according to the list of credits. In fact, the figure was specifically drawn for Carl Sagan's Time-Life book, *Planets* (1966). The drawing that decorates the title page has been adapted from the same source.

As a pictorial *history*, Tauber's production fares even worse. Factual errors abound. Contrary to his text, there is absolutely no evidence that Copernicus had to occupy himself with astrology (page 98), and in Kepler's music of the planets, the faster the planet, the higher the notes (page 124). Galileo's telescope did not contain three convex lenses (page 196), and Herschel never became Astronomer Royal (page 212).

Actually such flaws are rather minor, and although they detract from the book's reliability, they scarcely interfere with its pedagogical exposition. What dismays the historian of astronomy far more than a peppering of factual errors is the writing of "Whig history". That expression, introduced by Herbert Butterfield, refers to history seen from the vantage point of the victor; in the history of science, it means evaluating the past in the light of today's theory. It is Whig history of science, for example, to give the ancient heliocentric schemes of Aristarchus any special prominence. As physicist-historian Stephen Brush has said, credit for discovery should be given not so much for the originality of the concept as for the persuasiveness of the arguments; certainly

Oxford Books for Students

Physical Chemistry

P. W. Atkins

'It is a book of its time not only in content and outlook but in format and style too . . . . could well become a milestone in the development of text books of physical chemistry.' *Chemistry in Britain.* 'An important and original work.' *Education in Chemistry.* 'The author is to be congratulated on the production of such a good text and the publishers for its presentation at a price within the reach of students.' *British Book News.* £17.50 paper covers £7.95

Solutions Manual for Physical Chemistry

P. W. Atkins

This manual contains the author's detailed solutions of almost every one of the 1,060 problems contained in his textbook *Physical Chemistry.* It will be invaluable both to the instructors and lecturers who have adopted the parent text and to the students who use it themselves. Illustrated paper covers £4.50

Elementary Information Theory

D. S. Jones

Information theory is important to the designers of communication networks and electronic computers, and includes aspects of cryptography and linguistics. This book forms a one-term course for undergraduates in science and engineering. It begins with a short description of the relevant notions from probability theory. Then the quantity of information in a message is defined and its properties developed. The coding of messages is considered, followed by treatment of channel capacity, error-correcting codes, and continuous signals. £11 paper covers £4.95 *Oxford Applied Mathematics and Computing Science Series*

Biochemistry

Frank Bradley Armstrong and Thomas Peter Bennett

This book is an introductory text for first-year undergraduates studying biology, biochemistry, or chemistry at degree level. The topics treated include water as the solvent of life, cells as the biological units of molecular organization, proteins, carbohydrates, liquids and membranes, the basics of human nutrition, and hormones. £14

Thermodynamics and Statistical Mechanics

P. T. Landsberg

The basic ideas and mathematical formulations of thermodynamics are presented here in a concise and modern way. Topics covered include: negative temperatures; negative heat capacities; special and general relativistic effects; black hole thermodynamics; gravitational collapse; energy conversion problems; and efficiencies including simple heat pump theory. £9.75

The Solid State

An Introduction to the Physics of Crystals for Students of Physics, Materials Science, and Engineering

H. M. Rosenberg

The topics covered include basic crystal structure, diffraction of waves, dislocations, specific heat, phonons, thermal and electrical conductivity, the physics of p–n semiconductor junctions, and magnetic and dielectric properties. For the second edition a chapter on superconductivity has been added. £5.50 paper covers £2.95
Oxford Physics Series

Physical and Engineering Science for Technicians, Level I

R. J. Besanko and T. H. Jenkins

This new version of *General Engineering Science* is designed to cover the units in physical science and engineering science at Level 1 for students taking TEC Certificate and Diploma Programmes. Some additional material is included to satisfy college-devised units, and the book is also suitable for other courses at this level. Paper covers £2.95

Scientific Models and Man

The Herbert Spencer Lectures, 1976

Edited by Henry Harris

In these lectures a group of distinguished men from different disciplines describe how current work in their own subject is changing their view of the world. Scientific models have been enormously influential in transforming the way in which we look at ourselves and at the universe: this book gives some indication of the way the world is going to look tomorrow. £5.95

PETROLEUM GEOLOGY

SECONDARY RESERVOIR POROSITY IN THE COURSE OF SANDSTONE DIAGENESIS $215

Volkmar Schmidt
Manager, Geological Research and Services
Petro-Canada Ltd.

- Over 150 color slides
- Three, 60-minute audiocassettes
- Fully illustrated book of course notes

Secondary reservoir porosity is of interest to both academic and industrial geologists. Recognizing secondary porosity can mean the difference between a successful exploration prospect and lost opportunities for a new discovery.

Sponsored by
The American Association of Petroleum Geologists.

AGRICULTURE

METHODS OF MEASURING FEED DIGESTIBILITY IN RUMINANTS $110

Gordon Dryden
Queensland Agricultural College

- 80 color slides loaded in a Kodak carousel
- A 30-minute audiocassette, with slide/sound synchronization
- A study guide with pre- and post-test questions and answers

This program describes in detail the most cost efficient and scientifically accurate methods of measurement, with emphasis on the special requirements of each of the three standard methods of testing: *in vivo*, *in vitro* and grazing animal measurements. Each method is treated in a separate section of the program and then compared in terms of cost, accuracy and time and equipment requirements.

These programs can be ordered from:

The gravitational field between two bodies varies directly according to the product of their masses multiplied by the velocity of light

$$G = \frac{k\ Mm\ c}{(r^2)}$$

AN EXTENSION OF EINSTEIN'S THEORY OF GRAVITATION
by MORRIS REDMAN SPIVACK
6th EDITION, 1979

The theory of GRAVITATION, as bequeathed to us by ALBERT EINSTEIN, necessarily remains, in the present state of physics, DUALISTIC.

"For the present" (see "The Evolution of Physics", Einstein and Infeld) "we must still assume the existence of both: FIELD and MATTER."

A glance at Newton's Universal Law of Gravitation

$$F = \frac{k\ M_1\ M_2}{r^2}$$

reveals its deficiency — it represents only MATTER, so we must enter a factor representing the FIELD or the ENERGY of propagation of Gravitation — one of the principle characteristics of which is its velocity which is the same as the velocity of light. ("c")

In my formula G is the same as Einstein's $G\mu\nu$, the "metric tensor".
k = the gravitational constant.

M is one mass, m is another. These represent only a PART of the SOURCES of the field.

Mm c TOGETHER represent the entire field sources and are equivalent to Einstein's energy-stress tensor $T\mu\nu$.

When the gravitational fields are weak and the velocities minimal, mass-increase negligible, c = 1. Then Mm × 1 = Mm. In this case and only in this case, Newton's law of gravitation emerges (from the parentheses).

For deflection of a ray of light at rim of the SUN, c = 2.

For intermediate cases of mass-increase, the energy contribution of "c" lies between 1 and 2. The velocity "c" remains constant, only its energy burden varies.

For the excess motion of the perihelion of any planet, c = 3.

Circle No. 27 on Reader Enquiry Card.

the single sentence that has come down from antiquity about Aristarchus' cosmology contains no persuasive arguments.

Tauber gives a column to Aristarchus but his Whiggishness is generally more subtle, precisely the kind that distingushes textbooks and popular science from history. In describing the distances of stars, he goes straight to the trigonometrical parallaxes finally established by 1840, thus ignoring the intellectual breakthrough of the late seventeenth-century when astronomers recognised that stars were really distant suns and when they began to calculate reasonable distances photometrically. Similarly, in telling of Huygens' discovery of the rings of Saturn, he places this in the context of building better telescopes, not realising that the Dutch astronomer made his interpretation in mind's eyes at a time when the ring system was actually edge-on and invisible.

Tauber's presentation is rich in chronological facts rather than the historical facts that illuminate the actual process of discovery. In introducing galaxies under the heading "Island Universes" he alludes to Kant, Messier, the Herschels and Lord Rosse in a swift succession leading to the Shapley-Curtis debate in 1920.

He refers implicitly to the rotations of spiral nebulae found by van Maanan, but by Whiggishly suppressing explicit mention of these now-discredited measurements, he plants a confusing discontinuity into his story. Nor does he mention novae or red shifts, because he sorts these key elements in the historical account into other bins. There is nothing reprehensible about organising the material this way for instructional reasons — indeed, it probably leads more rapidly to an understanding of our modern ideas of the Universe.

In contrast, it is the task of the historian of science to show the development of science as a creative human activity, which for past science requires a sympathetic reconstruction of the motivations and limitations of a bygone period; this demands a selection of those facts that illuminate the understanding at that time, not the rather different group of facts now woven into our contemporary knowledge. I suspect that most prospective owners of Tauber's *Pictorial History* will be quite satisfied to get a relatively painless and accurate survey of modern astronomy, and would probably be disappointed if they got serious and accurate history of science. My plea to my scientific colleagues is that Tauber's work should be seen as a somewhat successful popularisation of science, but not as history of science. □

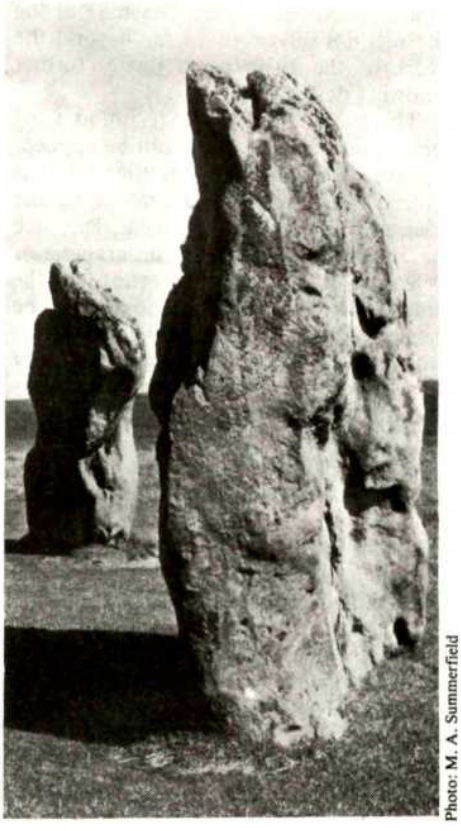
Owen Gingerich is Professor of Astronomy and of the History of Science at the Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts.

Prehistoric Avebury

R.J.C. Atkinson

Prehistoric Avebury. By Aubrey Burl. Pp. 275. (Yale University Press: New Haven, Connecticut, and London, 1979.) $19.95; £8.95.

NEXT to Stonehenge, Avebury is better known than any other prehistoric monument in Britain. About Stonehenge countless books have been written, good, indifferent and frankly lunatic; but about Avebury very little, even though, in the words of its first recorder, John Aubrey, it "does as much exceed in bigness the so renowned Stonehenge, as a Cathedral doeth a parish church". It has not escaped, even recently, the weird and uncritical lucubrations of the lunatic fringe; but until now there has been no comprehensive treatment of Avebury and its archaeological setting which could rival William Stukeley's *Abury* of 1743. This is not to ignore, of course, Dr Isobel Smith's *Windmill Hill and Avebury* (Oxford University Press, 1965) or *The Avebury Momuments* (HMSO, 1976) by the late Faith Vatcher and her husband, which are primary sources; but the first is an excavation report, and the second a concise guide for the visitor.



Aubrey Burl has now turned from British stone circles in general, on which he is the main authority, to a detailed study of one of the best known of them, on a scale and with a breadth of knowledge and vision rivalled only by Stukeley. This is a quite remarkable book, and a pleasure to read. It is intended for the intelligent layman, and in its presentation it has many of the attributes of more expensive 'coffee-table' books, with large format, well-spaced type and lavish illustrations, including more than a dozen full-page colour plates; but it also contains a very full set of notes and references, a comprehensive bibliography and a well-designed index.

The specialist reader (and maybe others as well) must make full use of the index, because the treatment is markedly discursive and the discussion of parts of Avebury, and of neighbouring sites, is widely dispersed throughout nine chapters. These are thematically arranged, with an underlying but not explicit chronological order, which is not that of the chronology of Avebury itself. As one familiar with the monuments from childhood, and with something of their archaeology from adolescence, I find this confusing and sometimes irritating; but I am not perhaps the reader Burl had in mind.

Throughout the book Burl has used his very wide reading to draw parallels between the available archaeological evidence, from Avebury and neighbouring sites, and sometimes from more distant sites in Britain, and ethnographical observations from other parts of the world, principally the documented customs for the living and the dead amongst various tribes of North and Central American Indians.

Some of these likenesses are so striking that the lay reader may be tempted to fall inadvertently into a logical trap, and to suppose that "because it could have been like that, therefore it was". Burl is obviously aware of this danger, and has taken some care, though perhaps not quite enough, to warn his readers of the pit-falls of facile conclusions based on comparisons of very different contexts in time and space, and of very diverse economies and environments. In the end ethnographic parallels can serve only to enlarge the field of conjecture of the prehistorian. They cannot tell us what our own past *was*, because this is unknowable in all but a trivial sense.

In the penultimate chapter ("The Purpose of Avebury") the author boldly gives his view, with suitable cautions, about the funerary and fertility rituals for which Avebury *may* have been built. Here, and indeed throughout the book, he displays the vision of a creative artist, in putting flesh and colour upon the bare bones of the archaeological evidence, no less pitifully exiguous here than in the other stone circles that he has studied. Amongst contemporary writers on prehistory he has the rare and enviable gift of evoking for the mind's eye the past-which-might-have-

Standing Stones at Avebury

Photo: M. A. Summerfield

been, without ever departing so far from the raw evidence as to strain the credence of the reader.

This admirable but discursive recension raises many questions about what is still unknown. Some of these can and should be answered, and soon, as far as available techniques allow.

In particular, the chronology of Avebury is still guess-work. On page 166 Burl gives a table of dates which divides the building of Avebury into three phases (interior stone circles; earthwork and main circle; avenues). This is plausible on the evidence available; but it is based wholly on the dating by analogy of pottery types, which is notoriously uncertain. The surviving finds from excavations can surely yield a suitable series for radiocarbon dating. Could not this be undertaken by the Department of the Environment, the official guardians of the monument?

Likewise, the former positions of the missing stones in the North and South circles, and in the eastern half of the great circle inside the ditch, still await identification. So do the stone-holes and buried stones of the Kennet Avenue, beyond the part excavated by Keiller and Piggott, and almost the whole of Stukeley's Beckhampton Avenue to the south-west. The latter, long regarded as the illusory product of Stukeley's perfervid imagination, has now been restored to credibility by recent finds. Further confirmation is needed, if the full extent of the Avebury complex is to be understood.

To search by excavation would be premature, because all excavation destroys more evidence, unrecognised, than it yields to the most skilled, experienced and conscientious excavator. The state of the art has not advanced so far beyond the work of the 1930s as to justify further knowing destruction.

There are, however, techniques of geophysical survey which can be applied, some of them developed specifically by the Ancient Monuments Laboratory of the Department of the Environment. There is a case here for a long-term programme of research, in which the diagnostic use of the simple hand-held probe should not be neglected. It is one of the defects of this book that these future problems are not spelled out, with non-destructive solutions (or at least programmes) of this kind.

There are other defects too. The values used by the author (page 175) in calculating the man-hours required for the building of the Avebury earthwork are grossly in error; but the corrections are largely self-cancelling, so that the result is still about 1.5 million man-hours. His second estimate (pages 175–76), which is about half of the first, is invalid because it is based on the raw evidence from the experimental earthwork on Overton Down, and makes no allowance for the scale-factor required. This is included in my own empirical formula on which the first estimate is founded.

Furthermore, although the neighbouring Neolithic causewayed camp on Windmill Hill, and the West Kennet Long Barrow, are discussed and interpreted in detail in the text, no plan is given of either. Worse still, there is no modern plan of Avebury itself, with the stones numbered, although individual stones are often referred to by their numbers in the text. These omissions mar what would otherwise be a quite excellent book. □

Boswellian enthusiasm for science

M. Rowan-Robinson

Broca's Brain: Reflections on the Romance of Science. By Carl Sagan. Pp.347. (Random House: New York; Hodder and Stoughton: London, UK, 1979.) $12.95; £6.95.

By his clear and witty writing and by his willingness to write about those eternally popular subjects, the planets and life on other worlds, Carl Sagan has captured a large audience. His last book *The Dragons of Eden,* on the evolution of human intelligence, won him a Pulitzer Prize, and the present book is already high on the American bestseller list. Sagan is a real phenomenon and we have to take him seriously as a major populariser of science today.

Broca's Brain opens with a superb evocation of the inner recesses of the Musée de l'Homme in Paris, where Sagan finds and muses on the preserved brain of Paul Broca, a pioneer of neurosurgery and anthropology in the mid-nineteenth century. This could almost be the opening of a novel in the manner of Balzac. The themes of the book are "the joys and social consequences of the scientific endeavor; borderline and pop science; the not entirely different subject of religious doctrine; the exploration of the planets and the search for extraterrestial life; and Albert Einstein . . .". The disparate nature of these themes is matched by an almost complete absence of continuity between the chapters of the book. This is a collection of lectures which Sagan has given on various occasions and of articles that have appeared in magazines as diverse as *Scientific American* on the one hand and *Playboy* and *TV Guide* on the other.

Although it is disappointing that these themes are not developed in the coherent and sustained way that we would expect from a purpose-written book, these essays are lively and entertaining, bubbling with amusing anecdotes about science and scientists. Sagan would make an excellent scientific Boswell. I particularly liked "A planet named George", about how the planets, satellites, and their craters and mountains, have come to have their exotic names. Not many people will be aware that the satellites of Jupiter are named after the illicit loves of his Greek counterpart, Zeus. Sagan feels it is rather unfair that Zeus' wife Hera does not get a mention. There is a marvellous, absurd picture of the international astronomical committee which decides these matters worrying about whether the Third World is sufficiently represented in the names of craters and asteroids and deciding that maybe some other creative humans besides astronomers and astronomers' wives ought to be so honoured.

However, Sagan aspires more to the role of Johnson, the moralist. He has a rather uncritical enthusiasm for science and technology and deplores the "sparse, unimaginative and ineffective efforts at science education" of American media and schools. He sees the best protection against abuses of science as a scientifically literate populace. "In exchange for freedom of inquiry, scientists are obliged to explain their work". But Sagan, while apparently admiring the anti-militaristic activities of Einstein and Russell, does not face up to the issue of military research, that all the most dangerous research (nuclear weapons, germ warfare and so on) is controlled by governments in an atmosphere of rigid secrecy.

There are a series of essays on pseudoscience and fringe science: astral projection, spirit rapping, precognitive dreams, UFOs, Velikovskianism, and so on. There is a particularly good essay on the problem of the remarkable astronomical knowledge of the Dogon

Susan P. Pauker, M.D., *Pediatrics, Harvard University*
Jeffrey Z. Rubin, Ph.D., *Psychology, Tufts University*
Foreword by **Jean Mayer,** *President, Tufts University*

The skill required to make rational decisions is considered to be one of the predominant traits of an educated person. This book addresses the process of making better decisions by drawing upon methods and techniques which have been developed in several disciplines. Written by an interdisciplinary team of educators from Tufts and Harvard Universities, the book is an outgrowth of a team-teaching effort of three years.

Autumn/Winter Books

Science in Action

John Lenihan
Illustrated by **John B Fleming**
A collection of lively, non-technical essays exploring the world of science and how it affects our everyday lives. The highly readable and entertaining text, accompanied by nearly 100 light-hearted cartoons, will appeal to anyone with an interest in science.
Nov 1979 x + 223pp 94 line illus 0-85498-035-0 £7.50

A new title in the series

Monographs on Astronomical Subjects

6 Cosmic X-ray Astronomy

D J Adams
Summarises our present knowledge of the subject and relates it to our understanding of the Galactic and extragalactic environment as revealed by the longer-established methods of optical and radio astronomy.
Jan 1980 approx 220pp illus 0-85274-253-3 approx £15.00

The first three titles in a new series

Medical Physics Handbooks

1 Ultrasonics

J P Woodcock
Intended primarily for physicists and engineers concerned with the biomedical applications of ultrasound. The principles of the technique are explained fully, and the book goes on to describe the generation, techniques and hazards of ultrasound, instrumental calibration and the surgical and therapeutic applications.
Nov 1979 x + 166pp illus 0-85274-506-0 £11.95

2 Computing Principles and Techniques

B L Vickery
This introductory text develops and imparts basic computer concepts in an essentially practical manner and, although examples of the computational and process control applications are drawn from usage in medical physics, is suitable for anyone entering the computer field.
Nov 1979 x + 182pp illus 0-85274-505-2 £11.95

3 Physical Principles of Audiology

P M Haughton
Provides a concise introduction to major topics in audiology. Intended primarily for readers with a physics or engineering background, but a previous knowledge of medicine or biology is not expected. Includes many tables of audiometric data, lists relevant national and international standards, and discusses calibration of audiometric equipment to those standards. Relevant to the growing number of physicists, audiological scientists and technicians responsible for the supervision of hospital audiology services.

LIFE SCIENCES

New and forthcoming titles in the 11-volume series of
ELECTRON MICROSCOPY IN HUMAN MEDICINE
Johannessen (ed), The Norwegian Radium Hospital, Oslo, Norway

Volume 6: NERVOUS SYSTEM, SENSORY ORGANS, AND RESPIRATORY TRACT
This volume deals with the nervous system, sensory organs, and respiratory tract, including metabolic and demyelinating conditions, virus diseases and tumors of the central nervous system, peripheral nerves, eye, inner ear, and upper and lower respiratory tract.
ISBN 0-07-032506-5 available Nov. 79 ca. 452 pp ca. $75.00

Volume 7: DIGESTIVE SYSTEM
This volume deals with the digestive system including the oral cavity, salivary glands, gastro-intestinal tract, and exocrine pancreas.
ISBN 0-07-032507-3 available Jan. 80 ca. 264pp ca. $49.50

Volume 8: THE LIVER
Volume 8 contains an extensive contribution on the liver, dealing with the normal organ, metabolic disorders, cholestasis, injury by drugs and toxins, autoimmune diseases, viral diseases, cirrhosis, and primary liver tumors. The main part of it is written by Professor Karoly Lapis in Budapest, one of the leading experts on ultrastructural liver pathology.
ISBN 0-07-032499-9 1979 271 pp $48.00

Volume 9: UROGENITAL SYSTEM AND BREAST
This volume deals with the urogenital system and breast, including kidney, lower urinary tract, male genitalia, spermatozoa, female genital tract, placenta, ovary, and mammary gland.
ISBN 0-07-032508-1 available Nov. 79 ca. 396 pp ca. $54.00

ACUTE MYOCARDIAL INFARCTION
(co-publication with Abacus Press)
Arthur Karassi, University School of Medicine, Bucharest, Romania
This is a major monograph in modern medical research in a field of growing importance and interest. It presents the results of an extensive program of experimental and clinical work on the epidemiology, clinics, treatment and complications of ischaemic heart disease, particularly myocardial infarction. This book should prove essential reading for all research workers and students in the field. It may also be useful to physicians who are involved in helping the organism in its struggle against environmental aggression.
ISBN 0-07-033296-7 1979 559pp $49.50

PHYSICS & CHEMISTRY

FIELD THEORY, THE RENORMALIZATION GROUP, AND CRITICAL PHENOMENA
International Series in Pure and Applied Physics
Daniel J. Amit, Hebrew University, Israel
The present monograph tries to unify the languages of traditionally separate fields of statistical physics and particle physics, and to provide both with access to the stock of concepts and experience of the other. The material contained herein has been the subject of intense research over the last few years. The application of the renormalization group and other field theoretic techniques to statistical mechanics has led to a profound improvement in understanding critical phenomena.
ISBN 0-07-001575-9 1978 XIV, 336pp $24.50

MOLECULAR ELECTRONIC STRUCTURES OF TRANSITION METAL COMPLEXES
C.J. Ballhausen, University of Copenhagen, Denmark
This monograph covers the electronic structures of transition metal complexes on the basis of molecular orbital theory, being the only existing theory which can give a simple consistent picture of the ground and excited molecular electronic states of inorganic complexes.
ISBN 0-07-003495-8 1979 248pp $34.00

MOLECULAR HYDRODYNAMICS
J.P. Boon, University of Brussels, Belgium and **S. Yip, M.I.T, USA**
The essential feature of this book consists in a comprehensive treatment of practical calculations of time correlation functions for the study of fluid dynamics at the molecular level. Tests of validity of such calculations are given by direct comparison of theoretical analyses, numerical results, and experimental data. In terms of the range of models and theoretical methods studied and the in-depth discussion of data interpretation this book is unique.
ISBN 0-07-006560-8 available Dec. 79 ca. 448pp ca. $48.00

QUANTUM FIELD THEORY
International Series in Pure and Applied Physics
C. Itzykson and **J. B. Zuber,** both Centre d'Etudes Nucleaires de Saclay, France
Providing a survey of quantum field theory, the book's contents range from the best established parts such as quantum electrodynamics to gauge field theories and renormalization group methods, including some of the most significant developments of the last decade. This pedagogical and unified text is designed for advanced students and researchers, especially in particle physics and related areas.
ISBN 0-07-032071-3 1979 ca 760pp $69.00 (tent.)

MATHEMATICS & STATISTICS

INFERENCE AND LINEAR MODELS
D.A.S. Fraser, University of Toronto, Canada
This monograph gives an organized presentation of current inference principles and methods, surveys inconsistencies and contradictions, and proposes resolutions of these. The book is of interest to mathematical statisticians and to applied statisticians in universities, industry, and research organizations.
ISBN 0-07-021910-9 1979 XII, 297pp $34.50

LINEAR SYSTEMS AND OPERATORS IN HILBERT SPACE
Paul A. Fuhrmann, Ben Gurion University of the Negev, Israel
Written by an internationally recognized authority in the field of systems theory, this monograph provides the first systematic description of systems theory in the context of infinite dimensional spaces. It tries to present to engineers a new powerful and elegant approach to the study of mathematical systems theory using fairly advanced techniques of operator theory in Hilbert spaces with an emphasis on the theory of invariant subspaces. To the mathematician systems theory is presented as an intellectually exciting and challenging field posing many problems of interest with some physical intuition as guide.
ISBN 0-07-022589-3 available Dec. 79 ca. 304pp ca. $34.50

MODERN METHODS IN TOPOLOGICAL VECTOR SPACES
Albert Wilansky, Lehigh University, Pennsylvania, USA
This book develops the theory and then, by means of examples and problems, carefully illustrates the necessity of various assumptions, raising and answering natural questions. It is well suited to the needs of advanced students and will be well received by pure mathematicians, especially by functional analysts and by those interested in point set topology.
ISBN 0-07-070180-6 1978 XIII, 298pp $34.50

ADVANCED BOOK PROGRAM

Circle No. 22 on Reader Enquiry Card.

people of Mali. As Sagan points out, their astronomical knowledge is just not remarkable enough to have been learnt from little green men in UFOs and could all have been learnt from contacts with Europeans. Sagan has performed a useful service here in collecting together these examples of public gullibility and demonstrating how a mixture of deliberate fraud and uncritical thinking has allowed millions to be bamboozled throughout history.

Yet when later in the book Sagan turns to discuss religion, his own critical apparatus seems to be switched off. "These mystical insights must mean something . . . If religions are fundamentally silly, why is it that so many people believe in them?" — an argument which could equally be applied to belief in UFOs or astral projection. Sagan's excitement by the phenomenon of mystical visions, and his curious attempt in the last chapter of the book to link these and all religious ideas to experiences associated with birth, suggest that Sagan is about to become a "born-again" believer in — something.

Although Sagan is rightly caustic about some of the absurdities of the popular pseudosciences he makes no effort ot discuss the problem of demarcation between science and pseudoscience, which has so occupied the attention of Karl Popper and his followers. Sagan's championing of science seems positively naive at times. Compared with the doctrines of pseudoscience ". . . science is more intricate and subtle, reveals a much richer universe and powerfully evokes our sense of wonder. And it has the additional and important virtue — to whatever extent the word has any meaning — of being true". Astrologers would obviously be happy with this statement with the word "astrology" substituted for "science". That is not what distinguishes science from pseudoscience.

On the exploration of the Solar System, Sagan is naturally interesting and thorough, for this is his own area of expertise. It would be interesting some day to hear what it is like for a scientist to work on one of these NASA missions. I find it rather touching that Sagan's belief in the existence of life elsewhere in the Universe is so passionate that he cannot bring himself to mention NASA's official interpretation of the Viking Lander mission to Mars, namely that Mars is chemically but not biologically active.

In comparing Sagan with popularisers of astronomy like Hoyle or those grand old rivals Eddington and Jeans, it has to be said that he has so far set himself an easier task. Those earlier masters set out to popularise the astronomical research of their times: they were ahead of the tastes of their public and tried to take their readers with them into the world of the modern astronomer. Carl Sagan, like the efforvescent Patrick Moore, talks for the most part about the areas already popular with the public: the Solar System, space travel, life in the Universe. Sagan's references to the "new" astronomies, radio, infrared, X-ray, and so on, seem to me to be perfunctory. He is not even particularly good on a topic which might be expected to have appealed to him, astronomy from space platforms. He refers to "an astronomical telescope in earth orbit called Copernicus", without mentioning that it is primarily the ultraviolet band that the instruments on the Copernicus satellite have opened up. He seems to think that X-ray emission from gas in clusters of galaxies was discovered by the recent HEAO satellites, whereas this was one of the achievements of the pioneering Uhuru satellite launched in 1970.

Considering that most of this material has been seen or heard by the public before, there are a couple of minor errors that ought to have been removed by now. It is not the orientation in space of a molecule that is quantised (page 17) but its angular momentum or energy. And galaxies do not disappear from view over the event horizon (page 296): on the contrary they swim into view over it. And as for the suggestion that psychedelic molecules exist in great abundance in plants because of artificial selection as a result of cultivation by human beings. . .

But these reservations do not diminish my enjoyment of the book. *Broca's Brain* is an entertaining collection of essays by a very good popular-science writer. □

Michael Rowan-Robinson is Reader in Astronomy at Queen Mary College, University of London, UK.

In the conflux of eternities

Freeman J. Dyson

In the Centre of Immensities. By Bernard Lovell. Pp. 174. (Hutchinson: London; Harper and Row: New York, 1979.) £5.50.

LOVELL'S life-work has been the exploration of the Universe by means of radio-telescopes. He was one of the small group of pioneers who understood thirty years ago that the new science of radio-astronomy would give us a wider and deeper view of the Universe than optical observations alone could provide. The achievements of the telescopes which he built have proved his vision right. In our modern theories of the structure and development of the Universe, the evidence obtained from radio observations plays a central and indispensable role.

In this book Lovell is not concerned with his own work as an observer. He is describing the historical growth of our understanding of the size and shape of the Universe and of our own situation within it. He puts this astronomical history within the context of the wider philosophical and religious struggles which have raged around the growth of modern science. He believes, in opposition to the prevailing fashion of scientific positivism, that the creative interaction between astronomy, philosophy and religion is not yet at an end. His purpose is to demonstrate that the discoveries of the past fifty years have confirmed rather than contradicted the words spoken by the mathematician-philosopher Whitehead in 1925: "When we consider what religion is for mankind, and what science is, it is no exaggeration to say that the future course of history depends upon the decision of this generation as to the relations between them."

To readers moderately conversant with the facts of astronomy, Lovell's expository chapters describing the growth of astronomical knowledge will be easy to follow but not particularly novel. On the technical level, his exposition does no differ substantially from the accounts given in other popular books such as Steven Weinberg's *The First Three Minutes* (André Deutsch/Fontana: London; Basic Books: New York; for review, see *Nature*, **267**, 291; 1977). The exciting things in Lovell's book are non-technical. His unique quality as a thinker is displayed in the philosophical and ethical discussions with which the book begins and ends, and in the breadth of his knowledge of history and literature. Chapter 1 starts with Saint Thomas Aquinas and ends with Thomas Carlyle, both of them great writers and profound thinkers, both of them synthesisers who tried to reconcile scientific truth with religious vision, both of them destined to be pushed aside by a younger generation of impatient fact-finders.

Lovell takes his title from Thomas Carlyle's "Sartor Resartus". Man, according to Carlyle, "sees and fashions for himself a Universe, with azure Starry Spaces, and long Thousands of Years. . . as it were, swathed in, and inextricably over-shrouded; yet it is sky-woven and worthy of a God. Stands he not thereby in the centre of Immensities, in the conflux of Eternities?" If Lovell's book succeeds in persuading a new generation of readers to look at the Universe through the eyes of Thomas Carlyle, it will have done us all a great service. □

Freeman J. Dyson is Professor of Physics at the Institute for Advanced Study, Princeton, New Jersey.

How physicists understand matter

Gerald Feinberg

The Forces of Nature. By P. C. W. Davies. Pp. 231. (Cambridge University Press: Cambridge and New York, 1979.) Hardback £12; paperback £4.25.

PAUL DAVIES is a mathematical physicist with both interest and talent in writing about modern physics for non-specialists, His previous works in this genre include *Space and Time in the Modern Universe* and *The Physics of Time Asymmetry.* There he treated aspects of relativity, thermodynamics and comology. In his present volume, *The Forces of Nature,* Davies turns to the central concern of twentieth-century physics, the structure of matter, and the interactions (forces) acting among subatomic particles. The book uses relatively little mathematics, and, in most places, requires no previous knowledge of physics on the readers' part. The result is a broad and usually clear survey of the ways in which physicists now understand matter. However, *The Forces of Nature* is missing a certain spark that was present in Davies' previous books. Also, it is somewhat marred by a number of inaccurate or misleading statements. These do not distort the main thrust of what Davies is doing, but they do make his treatment of some subjects unreliable. As the book does not try to present original contributions to physics, it is style, clarity and accuracy that are of greatest importance, and I will concentrate this review on these questions.

As might be expected from an author whose own research is highly mathematical, *The Forces of Nature* is very much a theorist's book. The ideas of physics are described in detail, but the experimental methods that led to these ideas are given perfunctory treatment. This is especially true of experiments carried out over the past thirty years. I cannot help thinking that this disparity in the treatment of theory and experiment will give readers a distorted view of how physics has developed in the past, and how it may proceed in the future.

The Forces of Nature begins with a brief introduction to Newtonian mechanics, and to electrical, magnetic and gravitational forces. The discussion of the forces is very clear and precise, but that of mechanics is less so. In particular, the description of energy is so vague that a reader will have trouble knowing what the concept means. This introductory chapter concludes with a section on special relativity theory.

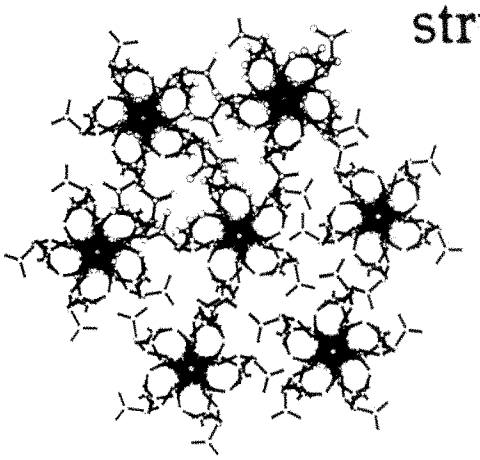
In his next chapter, Davies outlines the quantum theory of atomic structure as developed between 1900 and 1930. The essential feature of such an exposition is its treatment of quantum mechanics, perhaps the major intellectual achievement of the twentieth century. Davies approaches quantum mechanics through its wave aspect, which he explains very well, using analogies with musical instruments. He uses this discussion to indicate why electrons in an atom have discrete energy levels. However, the correct way of describing electrons in an atom, through the notion of a quantum state characterised by definite values of energy, angular momentum and spin, is not introduced clearly. As a result, Davies' discussion of the Pauli exclusion principle is vaguer than it need be. Furthermore, the distinction between fermions and bosons is described in such a way that one of the great achievements of quantum field theory, the connection between spin and statistics, seems a tautology. These problems could have been avoided with only a little more care.

Davies turns next to nuclear structure, and discusses the constituents of nuclei, nuclear stability, and alpha and beta radioactivity. These subjects, especially nuclear stability, are treated well. The description of beta radioactivity, with its distinction between neutrinos emitted in electron capture and antineutrinos emitted in neutron decay, leads into a discussion of antiparticles in general. Here Davies uses the Dirac hole theory, with its heavy reliance on the exclusion principle. This approach has some virtue in making the existence of positrons plausible, but it has two decisive disadvantages. One, mentioned as an afterthought by Davies, is that the hole theory does not apply to bosons, such as charged pions, which also have antiparticles. The other is that the hole theory obscures the fundamental symmetry between particles and antiparticles by making antiparticles seem like interlopers in a Universe composed of particles. That picture is, however, false, and the observed surplus of electrons over positrons, and of protons over antiprotons, is actually an empirical fact that needs explanation, which physicists are beginning to find in the early Universe. Although the hole theory did lead Dirac to predict antiparticles, it has probably outlived its usefulness and should be retired to the same honoured resting place for outmoded physical concepts as Maxwell's mechanical models of electromagnetic fields.

The notion of antiparticles next leads Davies to consider particle creation and annihilation, one of the more surprising consequences of the union of quantum mechanics and relativity. Davies approaches this through the use of quantum field theory, again skillfully using analogies with the behaviour of musical instruments. An emphasis on the field, rather than the particle aspect of relativistic quantum theory is not the rule among physicists today, most of whom think of quantised fields as no more than convenient mathematical tools for the description of interacting particles. Davies has an additional motive in emphasising fields, which is the desire to demystify the abrupt, unanalysable creations and destructions of particles, by treating these processes as more familiar changes in field amplitudes. However, the amplitudes of the fields are also quantised, and also change abruptly when the corresponding particles are created or destroyed. It is therefore no more accurate to think of transitions between states of a quantised field in classical terms than it is to think of transitions bestween particle states in that way. In both cases, transitions occur in a way that cannot be predicted in advance, although the transition can be measured after it does occur. It is not a difference here that impels us to use quantised fields. Davies does not mention recent work on solitons, and on vacuum excitations, which is a more basic effort to make the field aspect of relativistic quantum theory play a role separate from the particle aspect.

One of the important consequences of quantum field theory is the notion of virtual particles, and their effect on the properties of 'real' particles. Any existing configuration of particles spends part of its time in other states, which may consist of any combination of particles with the same value of conserved quantities, such a charge, as the original configuration. Davies gives a mostly clear exposition of this idea, both for the electromagnetic field, and for the fields associated with pi mesons. Along the way, he introduces the Feynman diagrams that are now universally used by physicists to symbolise various creation and annihilation processes. However, Davies does overstate the significance of virtual particles in one respect, when he says that the real particles produced in various collision processes are simply the virtual particles already present in the projectile and target. This picture is only true for special cases, such as the emission of very low energy photons in a collision between charges. It is not true for the production of high energy particles in collisions, in which case some of the emerging particles must be imagined to have been created in the collision process itself. William Blake's vision of "a World in a grain of sand" may be qualitatively satisfied by the existence of virtual particles, but it should not be taken as quantitatively sound.

The subject of the next section of *The Forces of Nature* is the profusion of subatomic particles discovered in recent years, and the phenomena of strong and weak interactions that they undergo. This description is fairly thorough and easy to



You can't afford to be without them!

enzyme and microbial technology

an international journal of original research and reviews into biotechnology and bioaffinity.
An interdisciplinary journal for biotechnologists which publishes original research, reviews, patent reports, a literature summary, views and comment — published quarterly.

International Journal of Biological Macromolecules
structure, function and interactions

This new international journal provides a broad and integrated coverage of the structure, function and properties of biological macromolecules and their assemblies - published alternate months.

Important Titles in Science and Medicine from Garland STPM Press...

HLA Antigens in Clinical Medicine and Biology
Edited by Soldano Ferrone, *Scripps Clinic and Research Foundation; et al.*
The serological, biological, and clinical aspects of histocompatibility antigens are examined by over fifty contributors from research institutions and hospitals throughout the world. 270 pp. Illus. Published.
ISBN 0-8240-7051-8 *$29.50*

The Handbook of Cancer Immunology: Volumes 1-5
Edited by Harold Waters, *National Institutes of Health*
A multi-volume series that gives comprehensive coverage of the state of current knowledge in cancer immunology for researchers, clinicians, and administrators.
Vol. 1: Basic Cancer-Related Immunology 352 pp. Illus. Published.
ISBN 0-8240-9864-1 *$37.50*
Vol. 2: Cellular Escape from Immune Destruction 248 pp. Illus. Published.
ISBN 0-8240-7001-1 *$37.50*
Vol. 3: Immune Status in Cancer Treatment and Prognosis—Part A 442 pp. Illus. Published.
ISBN 0-8240-7002-X *$37.50*
Vol. 4: Immune Status in Cancer Treatment and Prognosis—Part B 343 pp. Illus. Published.
ISBN 0-8240-7003-8 *$37.50*
Vol. 5: Immunotherapy 486 pp. Illus. Published.
ISBN 0-8240-7004-6 *$37.50*
Complete set price for Volumes 1-5: *$165.00*

Fetal and Newborn Cardiovascular Physiology: Volumes 1 & 2
Edited by Lawrence D. Longo, *Loma Linda University,* **and Daniel D. Reneau,** *Louisiana Technical University*
A two-volume work which discusses many of the theoretical concepts of the control of perinatal cardiac output and presents a physiological basis for therapeutic modalities.
Vol. 1: Developmental Aspects 669 pp. Illus. Published.
ISBN 0-8240-7012-7 *$39.50*
Vol. 2: Fetal and Newborn Circulation 529 pp. Illus. Published.
ISBN 0-8240-7013-5 *$39.50*
Set price for Volumes 1 & 2: *$65.00*

Handbook of Ethological Methods
By Philip N. Lehner, *Colorado State University*
A comprehensive description of the logical and practical methods of observing animal behavior for the student, researcher, and weekend wildlife observer. 421 pp. Illus. Published. ISBN 0-8240-7024-0 *$24.50*

Cat Behavior: The Predatory and Social Behavior of Domestic and Wild Cats
By Paul Leyhausen, *Max Planck Institute*
The classic work on the behavior of domestic and wild cats by the world's acknowledged expert on cat behavior. 356 pp. Illus. Published. ISBN 0-8240-7017-8 *$24.50*

Primate Ecology and Human Origins: Ecological Influences on Social Organizations
Edited by Irwin S. Bernstein and Euclid O. Smith, *Yerkes Regional Primate Research Center*
This book considers fundamental data about species living in the same and in different habitats, examines the connections between ecological and environmental variables and social organizations, and assesses various assumptions about the relation of social organization to ecology and phylogeny. 380 pp. Illus. Published.
ISBN 0-8240-7080-1 *$24.50*

The Development of Behavior: Comparative and Evolutionary Aspects
Edited by Gordon M. Burghardt, *University of Tennessee,* **and Marc Bekoff,** *University of Colorado*
An extensive discussion of the behavioral development of important invertebrate groups and all classes of vertebrates with sections on insects, fish, reptiles, birds, and mammals (including humans). 443 pp. Illus. Published. ISBN 0-8240-7015-1 *$32.50*

The Behavioral Significance of Color
Edited by Edward H. Burtt, Jr., *Ohio Wesleyan University*
Explains and discusses how coloration and the pattern of coloration of animals play a central role in the behavior and communication between and among different species. 470 pp. Illus. Published.
ISBN 0-8240-7016-X *$27.50*

Handbook of Fiber Optics: Theory and Application
Edited by Helmut F. Wolf, *Gnostic Concepts, Inc.*
A comprehensive and practical guide to the understanding and uses of communications systems based on optical fibers and containing, where appropriate, a discussion of economic aspects. Approx. 650 pp. Illus. Fall 1979 ISBN 0-8240-7054-2 *$47.50*

Handbook of Surfaces and Interfaces
Edited by Léonard Dobrzynski, *Institut Supérieur d'Electronique du Nord*
A comprehensive overview, in an on-going series, of the physics and chemistry of surfaces and interfaces.
Vol. 1: 441 pp. Illus. Published.
ISBN 0-8240-9857-9 *$34.50*
Vol. 2: 417 pp. Illus. Published.
ISBN 0-8240-9856-0 *$34.50*
Vol. 3: Surface Phonons and Polaritons. Approx. 420 pp. Illus. Published.
ISBN 0-8240-9855-2 *$34.50*

follow. One important part of the theory of subatomic particles treated in this section is the set of symmetry principles that these interactions satisfy. Davies' discussion of the basis of these principles is curiously Aristotelian, relying on the invariance properties of empty space. Although he is able to draw correct conclusions from this analysis, past experience should make us cautious about the extent to which such a style of argument can be trusted. It would be just as easy to infer Aristotle's form of inertia as Galileo's form from Davies' arguments.

The final section of *The Forces of Nature* deals with recent developments, such as the quark theory of hadrons, and the unified theories of weak and electromagnetic interactions. The discussion here is very up-to-date, and includes the discovery of the upsilon meson, and of parity non-conservation in deep inelastic electron scattering. There are also nice discussions of spontaneous symmetry breaking and of some reasons why quarks may not be observable. Once again, some things in the text are misstated, such as the mechanism by which charged pion decay occurs in the quark model.

A general stylistic objection to the book is that over and again Davies resorts to the phrase "it can be shown," or the like, a device that will probably annoy others as much as it does this reviewer. But on the whole, *The Forcers of Nature* is a considerable achievement in popular science writing. It is most likely to appeal to readers with an abstract turn of mind, who like deductive reconstructions of physical phenomena. □

Gerald Feinberg is a Professor of Physics at Columbia University, New York.

Einstein's ideals

Eugene Wigner

Albert Einstein, The Human Side: New Glimpses from His Archives. Selected and edited by Helen Dukas and Banesh Hoffman. Pp.168. (Princeton University Press: Princeton, New Jersey, and Guildford, UK, 1979.) $10; £4.95.

THE purpose of this book is to acquaint the reader with Einstein's social ideas, with his emotional life, with his convictions concerning the objectives man should strive for. And he surely abided by the ideals he put forward in his letters as well as any person could. The book is almost completely restricted to these aspects and contains hardly any information about Einstein's scientific accomplishments. It deals with what the authors call the human side.

As far as Einstein's own direct contributions to the book are concerned, these are almost completely restricted to letters which he sent out and a few which he drafted but did not send off. It does contain also two vitae — one written when he was 17, the other when he was a member of the Prussian Academy of Sciences, in Berlin at the age of 53 — and these are interesting to compare. Most of the rest of the book is due to two of his admirers: his almost life-long secretary Helen Dukas and his past friend and collaborator Banesh Hoffmann. They call themselves Selectors and Editors of the letter collection, but their contribution is actually much greater. It includes also the description of Einstein's relationship to the addressee of the letter, Einstein's attitude towards him or her, the motives leading Einstein to write the letter and the circumstances under which it was written. All this is done very clearly. They have also written a very nice introduction to the book.

Most of Einstein's letters were originally written in German and some were sent in that language. Others were drafted in German then translated into English by Einstein himself, but in some cases only the original German draft is available. In both these cases translations have been made by the Selectors and Editors, and in some cases this has been a difficult task. A particularly difficult case is that of the poems written by Einstein for inclusion in the letter. But whenever the letter's English formulation was not by Einstein himself, the German original is reproduced in the second part of the book ("German Originals", pp. 119-163). In a few cases, one must admit, the translation is less lively than the original, but it is good even in these cases.

The book does give the reader a vivid impression of the breadth of Einstein's interests, of his modesty and desire to help his fellow men and please them, of his convictions about what is good and what is evil. As to the first question, even the writer of this review, though he knew Einstein since about 1925, was not aware of all his interests. Besides all branches of physics, it also included music — his favourite composers were Bach and Mozart but he did have an affectionate regard for some of the later ones. His love of his violin was well-known to all his acquaintances. But in addition to these well-known interests, he showed great fondness towards the great philosophers of the past, and many of his letters are enlivened by philosophical remarks which give pleasure to the interested reader of the book and must have given even more pleasure to the original receipient of the letter. "The concept of a soul without a body seems to me empty". "What I see in Nature is a magnificent structure that we

LORD KELVIN: The Dynamic Victorian

by Harold & Tiby Sharlin

Lord Kelvin (1824-1907) meets no simple definition of scientist-engineer. The reader of this biography will be introduced to an extraordinary figure of a past era who in no way fits the image of the modern specialist. Kelvin was the nonpareil scientist of the 19th century, and his biography encompasses the dynamic scientific changes of the Victorian age.
340 p., 28 ill., £9.60

Circle No. 60 on Reader Enquiry Card.

can comprehend only very imperfectly, and that must fill a thinking person with a feeling of humility" (pp 39 and 40) are two such passages. But there are many, and even if one does not fully agree with them, all are refreshing. He also defended philosophy in general against its deprecators even when recognising its weakness: "Philosophy is like a mother who gave birth and endowed all other sciences" (p106) is perhaps an exaggeration but a well-meant one.

Einstein's love of poesie is also little recognised. He even wrote some poems, all of a slightly humorous nature, for his letters. About ten of these are contained in the book, and all are amusing.

Einstein's attitude towards religion is also clearly expressed in his letters. He felt — as many people do today — that its main role should be in the ethical domain, whereas its cognitive assertions should be more in the background. He also writes a good deal about the extinction of life — one must, with sadness, come to the conclusion that he enjoyed his last few years very little and considered the extinction of his life not only cognitively, but to some degree also emotionally, as a liberation from obligations.

Einstein's political convictions are also very apparent from his letters. These are, of course, generally known: he was opposed to all dictatorships, be they of the national socialistic — that is, Hitler-inspired and anti-semitic — or of communistic nature. In fact, one draft letter (pp110-112) is so vehement that it was not sent out but, according to the introduction preceding it, "must have brought him a feeling of relief".

The preceding discussion contains, of course, only a superficial review of the kind of information the reader will gain about Einstein's interests and thinking when reading this book. And the information will appear in a much more lively fashion than the foregoing summary presents it.

The book contains more than a hundred letters. To whom were they addressed? A few to his sister, Maja, a few more to his earliest physicist friends Zangger, Ehrenfest and Lanczos, but even more, about eight, to his psychiatrist friend Juliusburger. There is no letter to either of his wives or to the rest of his family. The rest of the letters are practically all answers to letters he received, each from a different person. With about half of these he had some acquaintance, the other's being written to please or comfort people he had not heard of before. Many of these letters, the writing of which was stimulated by kindness or compassion, contain passages which are truly memorable, and manifest deep insights. A few of the other letters are directed to editors of journals and about four to ministers of churches. These latter all have a strong political undertone.

It is not clear how the letters published were selected, nor is it clear how Einstein had chosen the letters to be answered. In one of his letters (p43) he praises the one which he answers as being very reasonable, in contrast to the hundreds of other letters which he was receiving, most of which, of course, he did not answer. It would also be interesting to know where and how the letters and the drafts of the letters published were found.

The English language part of the book (the first 115 pages) are arranged into 12 sections. These sections, however, have no titles and it is not clear on what basis the various letters are distributed into these sections. This has advantages if one reads the book from cover to cover — it is not easy to digest 10 philosophical letters in succession and not refreshing to read several complaints about politicians' misdeeds one after the other. But if one wants to recover a passage which one remembers vaguely, it would be good to have either a definite order of the articles in the book, or at least an index at the end of it. Similarly, the time ordering of the letters seems to be a random one. Thus, Section 6 (pp54-74) has articles dating from '33, then '51 and '53, then '27, again '33, '35, '21, and so on, ending up with one of '27. The subjects vary equally greatly, the first is political, the next a thank-you for the offer of financial help, the next refers to physics, then comes a letter to a student publication, then a praise of science in general and so it goes on. It is amusing to read all this, but a catalogue surely would be useful.

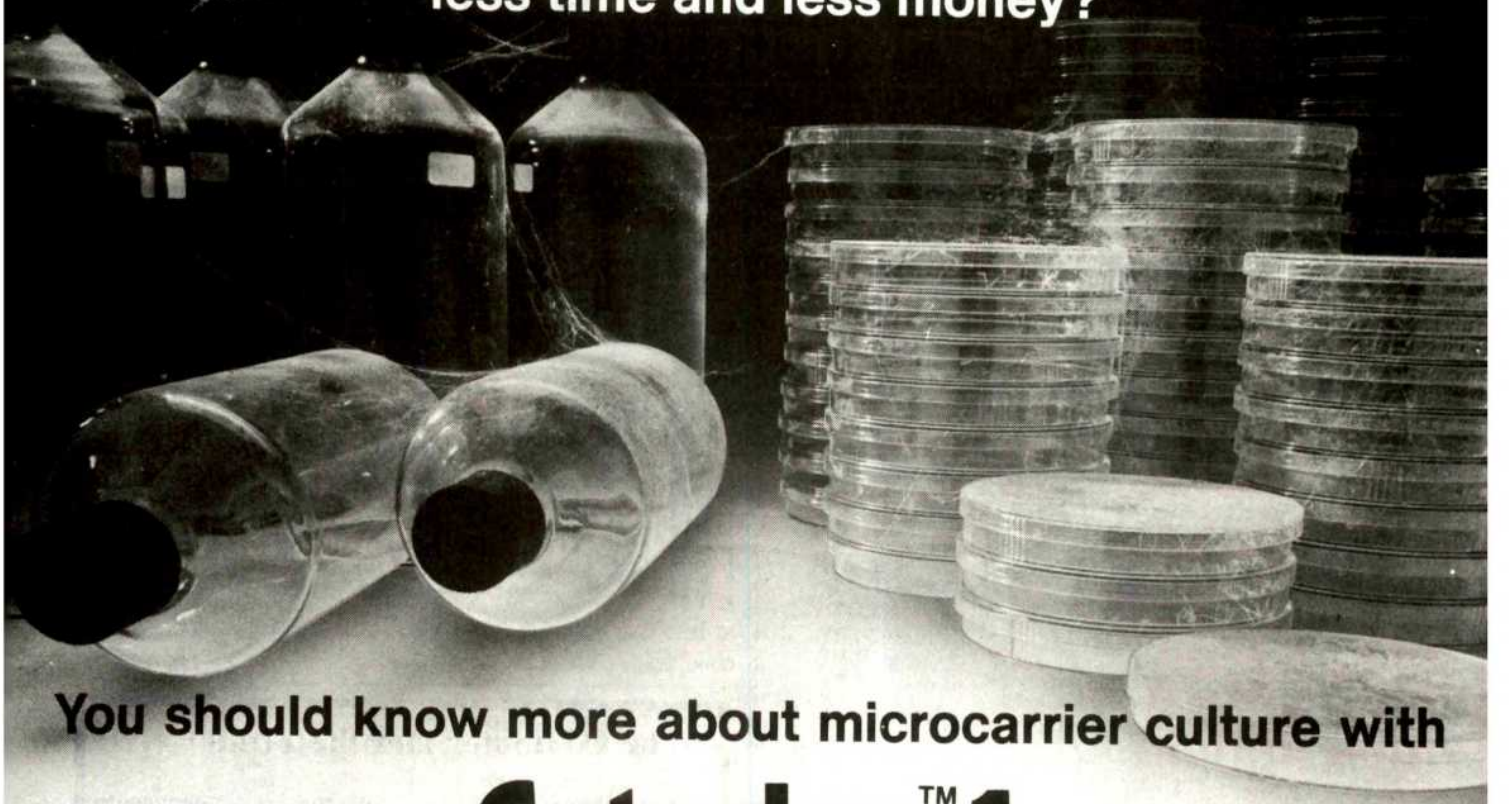
After all this criticism, let me compliment again the Selectors and Editors for the very good job they have done. It surely required not only knowledge but also devotion to the job and a true interest in the human side of Einstein. □

Eugene Wigner first met Einstein in 1925, while a student in Berlin. He had closer contact with him after 1933 when both lived in Princeton, New Jersey.

The quantum and its supporting planks

P.T. Landsberg

Black-Body Theory and the Quantum Discontinuity, 1894-1912. By T.S. Kuhn. Pp. 512. (Clarendon/Oxford University Press: Oxford and New York, 1978.) £12.



THE realisation that discontinuities (or quanta of energy) are needed for the description of microscopic phenomena represented one of the great transformations of human thought. Not that everything was believed to be continuous before that — the atomic concept of Democritus, the distinct notes of musical instruments, comets and explosions had been part of the intellectual furniture for centuries, and they certainly implied discontinuities of sorts. But they were not fundamental. Comets continued to be, when not in view; explosions could presumably be analysed into a more or less continuous sequence of chemical reactions; musical notes could be changed by altering the tension in the wire; and the constitution of atoms (if they existed, one would add in 1900) posed in any case intractable problems, for example, how could they be indivisible if they participated in the production of spectral lines? Indeed, as W.K. Clifford observed, an atom must be at least as complicated as a grand piano. Upon this placid scene, in which physics seemed to be approaching a completed structure, there floated gently (for it did not 'burst') Planck's theory of the energy density, as a function of frequency, of radiation when in thermal equilibrium with bodies at temperature T (black-body radiation). Shortly afterwards arose the problems of relativity, specific heat anomolies, etc., and so black-body radiation never lost the charisma of having been the first problem area which brought deep changes to classical physics. It did so by suggesting that an atom oscillating linearly at a frequency ν has available only discrete energies $h\nu$, $2h\nu$, . . . and so on, whereas classical theory would have allowed a continuous range of energies. Here h is the newly introduced constant of nature, now called Planck's constant.

At precisely what time and through whose pen did these discontinuities enter physics? The normal answer is that the year was 1900 and the man was Max Planck. In this scholarly study, which can boast 90 pages of notes and references, Kuhn suggests an amendment. Planck restricted the energy of N oscillators to be integral multiples of an energy unit, ε say, a type of "quantisation" already envisaged by Boltzmann in 1877, but he did not impose this constraint *on a single oscillator* until after 1906 (see p126), the year in which this requirement had been emphasised independently by Paul Ehrenfest and Einstein, "the two physicists who first recognised that Planck's black-body law could not be derived without restricting resonator energy to integral multiples of h or some equivalent non-classical step" (page ix).

In the Epilogue Kuhn discusses Planck's "second theory" of heat radiation (1911) which introduced the notion that the mean energy of an atomic oscillator goes to a constant and non-zero value at the lowest temperatures. Although this zero-point energy remained important, Planck's second theory was

Culturing cells?

Would you like a cell culture technique which gives you higher cell yields for less effort, less time and less money?

You should know more about microcarrier culture with

Cytodex™ 1

- High cell yields
- Much smaller working volumes
- Easy control and monitoring of cultures
- Simple harvesting of cells without centrifugation
- Saves you space, effort, time and money

One gram of Cytodex 1 gives you the same capacity for cell growth as 7 roller bottles or 76 standard Petri dishes.

Cytodex™ 1 – the new dimension in cell culture.

also to suffer profound amendments. By now, as Kuhn shows, the scientific community was turning to the quantum theory of specific heats.

Scientific community? In those far off days of the first Davis Cup matches, of Henry Ford and Thomas Mann, the number of authors who wrote on black-body theory did not exceed 20 even by 1914. By that time there were still only about sixty-five authors who wrote on the quantum theory, but the number was rapidly rising (as clear from the only three figures in the book). Does today's science harbour another growth point of this significance so that mathematically simple but conceptually gigantic leaps can again be made? Those who doubt that such a growth point can still be found in physics hope, like drowning men clutching at a straw, that it is perhaps still possible in biology. It is, however, a delight of science that there could yet be hope for physics. Who knows?

Mathematics is not popular with readers of book reviews, but to understand the background of Planck's arguments a gentle sniff of three results is needed. First, as black-body radiation does not depend on the material systems with which it is in contact (Kirchhoff, 1860), the simplest systems can be chosen. These are oscillators, N in number say for each frequency ν. The mean energy $U(\nu, T)$ of one of them is then simply related to the energy density $\varrho\ (\nu, T)$ of the radiation (Planck, 1899). Secondly, thermodynamics tells us how to find the mean entropy $S(U)$ of an oscillator in terms of U, provided $U(\nu, T)$ is known. (Example: if $U = kT$, then $dS/dU = 1/T = k/U$, so $S = k\ln U$). Thirdly, if one has a fundamental model to calculate the number W of so-called microstates of a system one can evaluate the entropy with the aid of a simple relation (Boltzmann 1877).

Now a remark about three Planck papers. In March 1900 he injected an empirical formula for ϱ due to Wien (1896) into this theoretical structure, and went from ϱ to U to S. But then he could only check certain properties of S and nothing revolutionary resulted.. In October 1900 he injected into the same structure a new (S, U)-relationship which contained the classical result $d^2S/dU^2 = -k/U^2$ and the Wien result $d^2S/dU^2 = -A/U$ as limits. It was a trial, or interpolation formula, and, passing in the opposite direction now, he inferred U and ϱ. The latter result was what has since become known as the famous Planck distribution law. "Permit me to direct your attention to this new formula" says Planck, "... I consider it to be the simplest apart from Wien's." But it had no firm basis in theory! Planck tells us that he worked very hard to find such a basis and on 14 December 1900, he produced a W-expression from the mechanics of oscillators. This is where he was very brief and not very clear. In any case, he now proceeded in the accepted logical direction from W to S to U and ϱ, and that was the essential job done. Or was it?

The problem for the studious reader, 75 years later, is: how did he get W? He says about the total energy of the N oscillators (we suppress the suffix ν, as we consider a given frequency), that "it is necessary" that it shall be considered to be "not a continuous, infinitely divisible quantity", but that "it shall be considered to be discrete and to consist of a finite number of equal magnitudes" (*Ann. Phys. 2*, 4,553; January, 1901), "which is the most essential point of the whole calculation" (*Verh. d. Dtsch. Phys, Ges.*, **2**, 237; December, 1900).

Kuhn unfortunately does not quote these passages, and argues that the fact that the total N-oscillator energy E_N is an integer n multiplied by an energy unit ε does not give the essence of the discontinuity: "If quantization is the subdivision of total energy into finite parts, then Boltzmann is its author" (p127). this is a possible point of view. An alternative, more generous, interpretation is to recall, first, that the oscillators are assumed far enough apart not to interact with each other. Hence, if one adds a single oscillator, then its average energy $E_1 = U$ must be the difference between the two Planckian results $E_{N+1} - E_N = n\varepsilon - m\varepsilon$ where n and m are integers. Hence Planck's result extends to $U = r\varepsilon$ $(r = 1, 2, \ldots)$. Secondly, what was still a fictitious model for Boltzmann, who after all took the limits $\varepsilon \to N \to \infty$, had become physically relevant in Planck's hands. Nevertheless, it is certainly true that Planck's reticence is puzzling, as has been pointed out (for example, by M.J. Klein, *Paul Ehrenfest*, Vol I, p228, North-Holland: Amsterdam, 1970; by H.-G. Schöpf, *Von Kirchoff bis Planck*, p106, Akademie: Berlin, 1978). Although there will therefore be discussions among historians of science sparked off by this book, we shall never know exactly what was in Planck's mind in 1900, nor is it very important to know. It strikes me that Planck knew the chain ϱ - U - S - W very well and had great confidence in his ϱ; so he worked backwards to find the W needed. Perhaps it was because Boltzmann had done much of the mathematics needed by Planck that Planck did not expound the theory of the W as clearly as he might have done. That there existed a sensible expression at all was to him, and rightly, an achievement. To infer single oscillator quantisation (which he might have done by the argument given above) was in 1900 against his wish, as he did not want to leave classical physics, as Kuhn reminds us again so clearly. In any case should an *average* oscillator energy be quantised? Surely not, a point apparently missed by some later commentators.

As to Einstein, he emerges as hardly ever wrong, as the following story shows. On 12 June 1913, Planck, Nernst,

Rubens and Warburg proposed Einstein for full membership of the Prussian Academy of Sciences, describing the achievements of the 34-year-old scientist in glowing terms. From the point of view of the book under review it is of interest that they did, however, remark: "That he has occasionally missed the target in his speculations, as for instance in his light quantum hypothesis, is not something that should count too severely against him; for even in the most exact of sciences it is not possible to introduce real advances without occasionally taking a risk". One can almost hear Planck's voice. It is a sobering thought for those called upon to judge the work of their peers in scientific academies, research committees, book reviews and promotion boards that this distinguished group of four was so devastatingly wrong; after all the light quantum hypothesis was essential to Einstein's explanation of the photoelectric effect which was to be cited by the Nobel Committee in 1921. This interesting matter did not escape Kuhn's eagle eye (though he attributes it to 1914) but he notes it only in passing (p182). Yet there it is. The careful and conservative Planck held back. Friend and supporter of Einstein's though he was - to the extent of risking the concentration camp by his 1933 declaration in support of Einstein - the photon picture of radiation was too much in advance of current thinking in 1905.

My main criticism of this fine book — so lovingly researched as to include abstracts, reviews and relevant citations of some of the key papers — is that this very detail has prevented a tight organisation of the material and of the author's conclusions, which are therefore somewhat buried at various points, in spite of a good index. The Epilogue might have included a two- or three-page forward look into the 1920s, for reasons which will be touched on below.

An alert reader may ask a question, to which the book does not supply an answer, as to whether systems other than oscillators, for example rotators, were studied in contact with black-body radiation. If not, why not? In any case, the element of confusion between E_N and E_1 and between quantising $E_1 = U$ as against quantising the unaveraged single oscillator energy, means that the Planck argument has to be replaced. By treating radiation as a gas of "light quanta" and introducing the notion of indistinguishability of quanta of given energy, Bose (1924) gave an argument which no longer depended on any parameters of the material system in contact with the radiation. In a modern exposition Bose's W had the same form as Planck's, $W = (N + P - 1)!/P!(N - 1)!$. However, Planck oscillator number N became the number of states in a typical narrow energy range of the quanta considered, and Planck's integer $P = E_N/\varepsilon$ became the number of quanta to be distributed over these states in an optimal manner. (For Planck P was the number of discrete energy elements to be distributed over the N oscillators). Although this was much more satisfactory, the result was approximate (Stirling's approximation). On the whole this does not worry people. However, one cannot conceal that this approximation breaks down for the small number of quanta which can be found in high energies, and I found (1954) that if the Stirling approximation is improved one gets into trouble. The Planck law *can* be derived as an exact result, but as far as I know only by using the grand canonical ensemble or by taking a limit.

Two queries may be in order in conclusion. In "overblowing" a wind instrument the note jumps as a higher mode is excited. This is typical of *classical* discontinuities. They are not mentioned in the book but it would be of interest to study them, together with Schrödinger's and Planck's approaches, in a historical context. Secondly, the case studied here suggests (though one must not generalise from one example) that a great scientific advance — a revolution if you like — tends to dissolve into little steps on closer inspection. The same man may take different steps at different times, so that he may in the end have made a major contribution; but small steps they are nevertheless. If this is a general rule, with a few exceptions such as general relativity, it would be interesting to hear Kuhn, the author of the *Structure of Scientific Revolutions* (1962) consider it in the light of this latest book. The topic itself has been much discussed of course (for example, by S. Toulmin, *Human Understanding*, Vol. 1, 1972), but it is particularly interesting in connection with the story of black-body radiation. □

Direct imaging of the twin QSOs 0957+561 A and B: the gravitational lens interpretation

Mark T. Adams & Todd A. Boroson

Steward Observatory, University of Arizona, Tucson, Arizona 85721

Recent observations have indicated that the twin quasistellar objects 0957+561 A and B might be images produced by a gravitational lens. New direct observations are presented, including the probable detection of an object between the two quasistellar objects. The implications of these observations for the nature of the twin quasistellar objects are discussed.

WALSH *ET AL.*[1] have recently announced the discovery of a pair of quasistellar objects (QSOs) that are separated by 5.7 arc s and that have the same emission redshift, 1.405. These QSOs, 0957+561 A and B, were found to have several similarities. The redshifts of the C IV λ1,549 and C III] λ1,909 emission lines are significantly different in each QSO but identical to the accuracy of measurement between the two objects. The equivalent widths of these two lines are, respectively, the same in the two QSOs. Furthermore, a strong low-Δz absorption system at approximately the same redshift was seen in the spectrum of each object. Subsequent spectroscopic observations at the Multiple Mirror Telescope by Weymann *et al.*[2] revealed that the redshifts of the absorption systems in the two QSOs differed by 7 ± 15 km s^{-1}. The amazing similarities between these two objects have led to speculations[1,2] that the image of a single QSO was being split by a gravitational lens in the line of sight, and to crude calculations of the parameters necessary to produce such an effect.

The large mass implied by these calculations ($\sim 10^{13} M_{\odot}$) led us to believe that if such an object existed and was a particularly massive galaxy, it should be visible on a suitably deep, direct picture of the region. Also, because the images formed by a gravitational lens are not expected to be circular, it might be instructive to examine the size and shape of the images of the QSOs in such a picture.

Observations

The two QSOs were observed on 15 June 1979 with the Kitt Peak National Observatory (KPNO) 4-m telescope and the ISIT video camera. Four 13.6-min. integrations were obtained through an *R* filter. The resulting field in this configuration is ~75 arc s on a side; each pixel is ~0.29 arc s. The seeing was estimated at the telescope to be 2 arc s. Basic reduction of the data included subtraction of a dark frame and division of the object field by a flat-field exposure obtained through the same filter.

These four frames were inspected using the KPNO interactive picture processing system (IPPS). This inspection revealed that the quality of the images in the last exposure was significantly poorer than in the other three due to deterioration of the seeing at high air mass (sec $z \sim 2.2$).

In each of the first three frames the centre of gravity of each QSO image was determined. These centres agree to ≤1 pixel frame-to-frame. An equal weight average of these three exposures was then calculated and used for all subsequent measurements. This final picture is shown in Fig. 1.

Analysis

Several different types of measurements were made using the IPPS surface brightness routines written by Strom[3].

Simulated aperture photometry of the two QSOs in our averaged frame provides a scale factor for conversion of our arbitrary intensity units into *R* magnitudes. The adopted *R* magnitudes for the two QSOs were taken from Walsh *et al.*[1]. The determined relationship is $m_R = -2.5 \log I + 30.6$, where I is the total intensity within the aperture. Magnitudes obtained in this manner are probably accurate to ±0.5.

We attempted to detect or set an upper limit to any excess flux present between the two QSOs. First, an average value for the sky was determined by sampling several blank areas adjacent to the QSOs. A sky surface brightness of 20.5 mag arc s^{-2} in *R* was measured. Next, the contribution of each QSO to the point midway between them was determined. The flux in a series of 1.16 arc s circular apertures, arranged as shown in Fig. 2, was measured. The radius of each semicircle is equal to half the separation of the two QSOs. This procedure was used to estimate the possible error due to asymmetric images.

This possibility has important implications for the significance of a detection. If we find that the standard deviation of the measurements among the apertures is less than or equal to that expected from measurement uncertainties (for example, photon

0028-0836/79/450183—03$01.00

© 1979 Macmillan Journals Ltd

statistics, flat-field and dark-count uncertainties, nonlinearity in the detector), we can justify using the standard deviation of the mean as an estimate of the accuracy. If, however, the variation among the apertures around the QSOs is larger than that expected from measurement uncertainties, we must conclude that our apertures are sampling a variety of values, and in this case the standard deviation of a single aperture is a better estimate of the accuracy.

Unfortunately, the results of this comparison are somewhat ambiguous. Measurement uncertainties were determined by sampling the sky in a series of adjacent apertures, yielding a variation of ~1%. Around QSO A, the standard deviation of the measurements exceeds that expected by ~45%. A χ^2 test indicates a 15% probability of a distribution as unfavourable as that observed arising from the expected gaussian distribution. Around QSO B, the standard deviation is almost twice that predicted by measurement errors. The variation in this case, however, seems to be systematic in that the four apertures most nearly along the line perpendicular to the separation of the two QSOs are much higher than the other four. The most likely explanation of this asymmetry is that we have marginally resolved QSO B in the perpendicular direction.

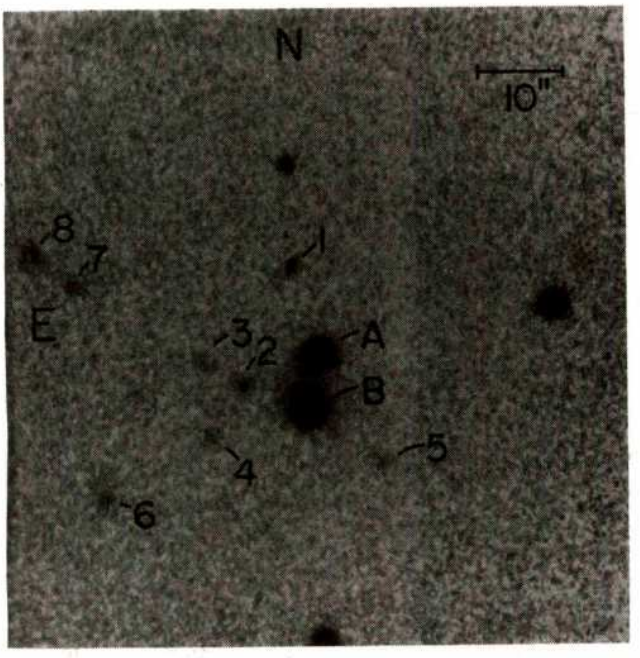

Fig. 1 The final averaged R-band picture of the region surrounding 0957+561 A and B. The eight galaxies listed in Table 2 are indicated.

Because of the difficulty in ascertaining which types of errors dominate, we will consider two cases. The flux measurements for each case are presented in Table 1. In case 1 we consider the variation around QSO A to be statistical. For QSO B, we use only the four apertures most nearly along the line of separation and consider the variation among them to be statistical. In case 2 we consider all variations to be real and, therefore, use all points in the mean; the quoted errors are the standard deviation of a single measurement. Case 1 indicates a 5.4 σ detection which corresponds to $m_R = 23.1$; case 2 indicates a 2.0 σ detection which corresponds to $m_R = 23.4$.

Visual examination of our data suggested that the image of QSO B is larger than that of QSO A. To quantify this we measured the radial profiles of the two QSOs perpendicular to their separation. Since the central surface brightness of QSO B is ~12% lower than that of QSO A, we scaled up the measurements of QSO B by this amount before comparing them with QSO A. The resulting profiles (Fig. 3) clearly show that at low surface brightness QSO B is ~10% broader than QSO A.

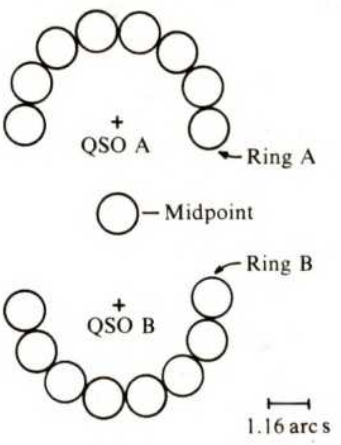

Fig. 2. The geometric configuration used in the photometric measurements.

We measured the magnitudes of eight faint nonstellar objects in the field. These measurements were obtained through (1) a 1.16-arc s aperture for comparison with our midpoint photometry; and (2) a 6.44-arc s aperture which should contain essentially all the light of each galaxy (Table 2). The galaxy designations are shown in Fig. 1.

Discussion

Two ways of qualitatively accounting for the original observations have been proposed. The first hypothesis is that the two objects are separate QSOs that, by chance or environment, have evolved with remarkably similar characteristics. This hypothesis requires that almost identical absorbing clouds are found in the line of sight to both QSOs at precisely the same redshift. The second interpretation involves a single QSO whose image has been split by a gravitational lens.

To discuss the gravitational lens hypothesis more quantitatively, we begin by calculating the expected characteristics of the lens object. This calculation involves the following three assumptions. (1) The object is a galaxy with a velocity dispersion given by

$$[\sigma\ (\mathrm{km\ s^{-1}})]^2 = \frac{106{,}875\ (1+z_L)\,[(1+z_Q)^2-1]}{[(1+z_Q)^2-(1+z_L)^2]} \qquad (1)$$

where z_L is the redshift of the lens, z_Q is the redshift of the QSO. This formula is derived from equation (1) of Weyman *et al.*[2] using their values of θ_{sep} and n. The mass is derived from this by assuming that the galaxy is an isothermal sphere.

Table 1 Excess flux measurements

	Case 1 Measurement error	Case 2 Real variation
Ring A	798.0±66.6	798.0±188.5
Ring B	1,115.9±62.8	1,360.9±291.5
Midpoint	2,904.1±158.3	2,904.1±158.3
Excess	990.2±184.7	745.2±382.0

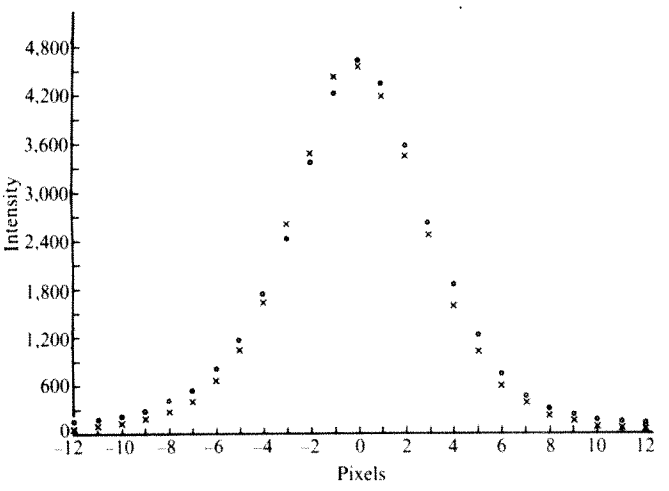

Fig. 3 Profiles of the two QSOs (×, QSO A; ○, QSO B) in the direction perpendicular to their separation. The intensities have been normalised to the central three pixels of QSO A.

(2) As the mass-to-light ratios M/L for galaxies are poorly determined, we have done the calculation for two cases: $M/L = 5$ and $M/L = 30$ in solar units.

(3) $H_0 = 50$ km s^{-1} Mpc^{-1} and $q_0 = 0$. Table 3 lists, for various possible z_L values, the absolute R magnitude of the lens galaxy, M_R, the total apparent R magnitude of the lens galaxy, m_T, and the expected R magnitude through a 1.16-arc s diameter aperture m_{ap}. R-band K corrections were extrapolated from the published V-band K corrections of Pence[4]. The magnitude difference between m_T and m_{ap} was calculated from the M87 surface photometry of Young *et al.*[5] by comparing the flux in the small aperture with that in a 6 arc s aperture at each redshift. The resulting magnitudes in Table 3 are very uncertain, primarily due to the K corrections and luminosity evolution which we have ignored. Moreover, comparison of our measured magnitude with the numbers in Table 3 is hindered by uncertainty in the absolute calibration and ignorance of the correct M/L. Thus differences of up to 1 mag in this comparison are within the possible range of error.

The possible interpretations of our detection of an $m_R = 23.1$ object between the two QSO images are: (1) the object could be the lens galaxy; (2) the object could be a faint field galaxy in the line of sight; (3) the object could be the galaxy responsible for the absorption system.

If the detected object is the lens galaxy, it can be seen from Table 3 that it must be located at very nearly the QSO redshift, or it must have a large M/L. The extended profile of QSO B may argue for the validity of the lens interpretation. If the lens is circular and slightly out of the line of sight, it is expected that the two images will not be identical. The image further from the lens will be brighter and more elongated perpendicular to the separation of the images[6]. Note that QSO B has a redder continuum than QSO A[1]. If this is indicative of greater extinction, then QSO B is the brighter of the two.

The other two interpretations of the nature of the object between the QSO images argue for the 'non-lens' picture. The explanation that the object is a field galaxy located by chance in the line of sight is unlikely because of the probability of finding a galaxy brighter than 23.1 mag in a 1.16-arc s aperture. Using the faint galaxy counts of Tyson and Jarvis[7], we estimate that the likelihood of this is $<10^{-3}$. These counts and the work of Kron[8] indicate that the expected number of galaxies visible in our field is ~3–5, and thus it is unlikely that the eight galaxies seen are associated with a rich cluster.

The third possibility, that the object is the galaxy responsible for the absorption in the two QSOs 65 kpc apart, cannot be ruled out by this statistical argument. However, the primary argument against this explanation is the very large luminosity required for the absorbing galaxy. Even in the optimistic M/L case, the necessary luminosity requires that $M_V < -26$. This seems unlikely, considering the local galaxy luminosity function from which it seems that significant luminosity evolution would be needed to attain such a value. The evidence at this time[7,8] favours little, if any, luminosity evolution at this magnitude. Also, no QSO with a redshift as large as 1.4 has been detected as nonstellar.

Table 2 Field galaxy photometry

No.	m_R (aperture 1.16 arc s)	m_R (aperture 6.44 arc s)

1.0	26.6	20.4	21.0	24.6	22.4	23.0
1.2	27.4	20.7	21.3	25.5	22.6	23.2

Conclusions

We have obtained a deep R-band picture of the double QSO 0957+561 A and B. We have detected excess flux between the two QSOs which corresponds to $m_R \simeq 23.1$. The significance of this detection strongly depends on the nature of the errors. QSO B was found to have a more extended radial profile than QSO A in the direction perpendicular to their separation.

Both these results can be interpreted as consistent with the two competing hypotheses: a gravitational lens or two distinct QSOs. However, a statistical argument favours the gravitational lens interpretation.

We thank Drs S. Strom, R. Weymann, F. Chaffee, J. Liebert and T. Sargent for helpful discussions and Hal Halbedel for technical assistance. The authors were visiting observers at Kitt Peak National Observatory, operated under contract with the NSF.

Oxidation of aerosoled ultrafine iron particles

K. Haneda* & A. H. Morrish

Department of Physics, University of Manitoba, Winnipeg, Manitoba, Canada R3T 2N2

Aerosoled ultrafine iron particles, in the few hundred ångstrom size range, have been subjected to different oxidation modes. X-ray and Mössbauer techniques have been used to study the morphology of the oxide scales and the diminution of the recoilless fractions and the hyperfine fields.

ULTRAFINE particles of iron are of considerable interest as they form the active component of magnetic tapes now under development by the recording industry. A way of making small metal particles is by an aerosol or evaporation technique developed more than a decade ago[1-3]. In essence, metals are evaporated in an inert gas atmosphere at reduced pressure. The metallic atoms have a reduced mean-free-path, and eventually condense to form small particles. Particle size can be controlled to some extent by changing the pressure or species of the inert gas.

Very small iron particles are pyrophoric. The oxidation of metallic iron in the form of sheets, foils, or even single crystals has been studied extensively[4-7]; the motivation has been an interest in corrosion and passivation processes. Little is known about the oxide layers formed on the surface of ultrafine iron particles[8-10]; it is therefore timely and relevant to investigate the oxidation modes for such particles.

Earlier experiments in our laboratory showed the oxide layer to be composed of small crystallites with the spinel structure[10], probably a mixture of Fe_3O_4 and γ-Fe_2O_3. Further, for a sample with particles an average diameter of 238 Å, only a slight Mössbauer absorption was observed at room temperature, whereas at 77 K a well-defined hyperfine-split spectrum was obtained[11]. Apparently at 300 K most of the particles experience a recoil on absorption of the γ-ray photon. The Debye–Waller factor for small particles has attracted the attention of many researchers, and does not yet seem to be settled[12-18].

Iron particles can be passivated by an O_2 and N_2 gas mixture low in oxygen content[19], that is, by a slow oxidation. At the other extreme, on exposure to open air even at room temperature, the ultrafine particles glow, indicating that a relatively high temperature is reached. Hence, the chemical and physical properties of ultrafine particles may be different, depending on whether a slow or a fast oxidation is used. This article reports on an X-ray and Mössbauer study of aerosoled iron particles subjected to different extreme oxidation modes. Special attention is given to the morphology of the oxide, the recoilless fraction, and the hyperfine fields.

Oxidation experiments

Five samples of small iron particles in the 200–400 Å range were prepared by evaporation into a 1 to 3 torr helium gas atmosphere. They were produced at Osaka University, Japan, and made available through Professor A. Tasaki and Dr M. Takao. The samples labelled A–E were collected in sample containers, and sealed in a helium gas atmosphere.

The oxidation of the samples was achieved in the following way. Sample E was immediately exposed to air, and after completion of the rapid oxidation was quenched and stored in ethyl alcohol. Sample D was suddenly exposed to air about 3 weeks later; it glowed and the powder colour changed rapidly from black to dark brown. Thus, samples D and E were subjected to fast oxidation. Samples A, B and C were oxidised slowly by air entering through a small leak in the seal. Although this slow leak continued over a period of a few weeks, the actual oxidation rates are of course unknown. When samples A, B and C were exposed to air, no further changes occurred, indicating that complete passivation had taken place, as suggested by Tasaki *et al.*[20]. Indeed, X-ray and Mössbauer data showed that another sample, similar to C, underwent no measurable changes over a 3-year period.

The average particle size of each sample was determined by the Brunauer–Emmett–Teller (BET) nitrogen adsorption method assuming a spherical shape. The results are listed in Table 1.

Table 1 Properties of samples A, B, C, D and E

Sample	Particle size (Å)	Crystallite size (Å)* Fe	Crystallite size (Å)* Oxide	Composition (%)† Fe	Composition (%)† Oxide	Mössbauer absorption 300 K
A	380	133	68	18	82	Almost none

E	366		120		≈100	Hyperfine split

* Determined from X-ray line broadening using (311) for cubic oxide and (110) for metallic Fe.
† Obtained from Mössbauer absorption area.

X-ray measurements

X-ray diffractograms were taken for the five samples using CoKα radiation; part of the recorder plots is shown in Fig. 1. For slowly oxidised samples (A, B, C) the diffraction profiles indicate two phases—one with the crystal structure of ordinary α-Fe, and the other, constituting a significant fraction, has the structure of spinel iron oxide, either magnetite (Fe_3O_4), γ-Fe_2O_3 or a mixture of both oxides. No line corresponding to α-Fe_2O_3 (haematite) was detected. Although the superlattice lines peculiar to γ-Fe_2O_3 were not observed, the presence of γ-Fe_2O_3 is not ruled out for the following reasons. First, as shown in our earlier study[21], the transformation from Fe_3O_4 to γ-Fe_2O_3 takes place with good probability in the small particle region. Second, the vacancy-ordered superstructure lines associated with bulk γ-Fe_2O_3 are reduced or absent in ultrafine particles because then the vacancies, although they exclusively occupy B sites, are

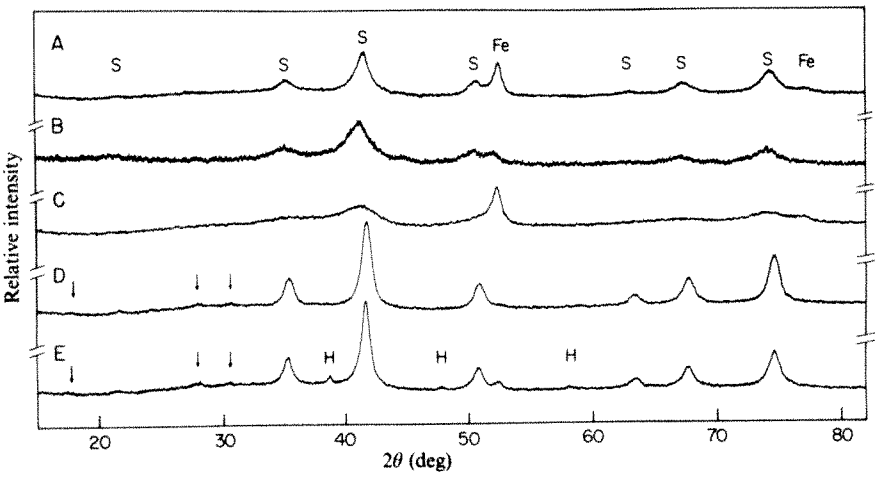

Fig. 1 X-ray diffraction recorder plots for samples A, B, C, D and E. Here 2θ is twice the Bragg angle. S, spinel type iron-oxide phase; Fe, Fe phase; H, α-Fe_2O_3 phase; arrow, vacancy-ordered superlattice line peculiar to γ-Fe_2O_3.

disordered[22]. Third, every oxide diffraction line for the three samples is slightly shifted to higher angles, that is, towards the γ-Fe_2O_3 and away from the Fe_3O_4 positions. Therefore, the data probably imply that the oxide is a mixture of stoichiometric Fe_3O_4 and γ-Fe_2O_3.

Sample D, oxidised by the fast mode, does exhibit faint vacancy-ordered superlattice X-ray lines. No line of metallic iron or α-Fe_2O_3 was detected. In addition, both the X-ray line positions and the dark brownish colour are close to those associated with γ-Fe_2O_3. It follows that this sample is almost entirely composed of γ-Fe_2O_3.

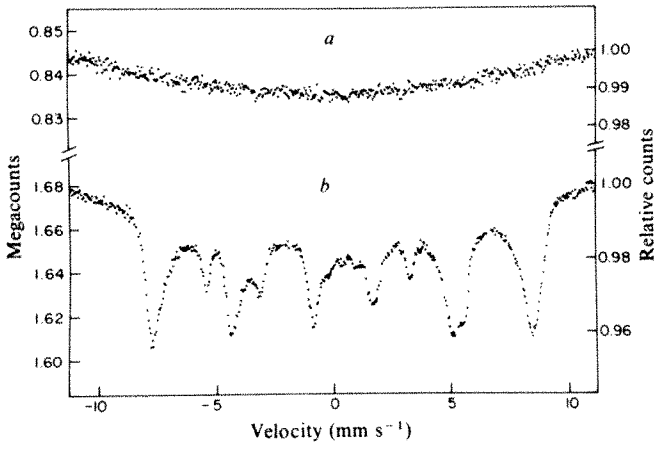

Fig. 2 Mössbauer spectra for aerosoled Fe particles subject to slow oxidation, sample A (380 Å). *a*, At 300 K; *b*, at 77 K.

The pattern for sample E, oxidised quickly then quenched in C_2H_5OH, shows γ-Fe_2O_3 lines, including superlattice ones, as well as low intensity α-Fe_2O_3 and α-Fe lines. The presence of the latter suggests that the oxidation may have been faster for sample E than D, and that the quenching may have been a factor.

The variation in the X-ray linewidths is of particular interest. For samples A, B and C, the spinel lines are much broader than those of iron. In addition, the spinel linewidths of these three samples are significantly different. Even in the slow-oxidation mode, physical and chemical processes may depend delicately on the actual oxidation rate. These observations imply a considerable difference in the iron-oxide crystallite size for the A, B and C samples. Further, the iron-oxide layer is apparently not continuous, but consists of very fine crystallites. A similar observation was made by Boggs *et al.*[23] in a microscopic study of the oxidation process for iron.

Although the lines for samples D and E are much sharper than for A, B and C, they, nevertheless, are still relatively broad. The average crystallite sizes for the oxide and the metallic iron were determined for all samples using the Scherrer relation (Table 1). The faint superlattice lines of samples D and E, observed in spite of the relatively small average crystallite size, seems to imply that some of the crystallites are large enough to have developed vacancy ordering.

To generalise, the X-ray studies imply that on slow oxidation of ultrafine aerosoled iron particles only partial oxidation occurs with the formation of finely divided oxide crystallites on the iron. On the other hand, on fast oxidation, all the iron is oxidised into crystallites that are relatively large.

Mössbauer studies

Mössbauer measurements were made on the five samples at 77 and 300 K; some spectra are shown in Figs 2, 3 and 4. To make an absorber, the powder was dispersed in acetone, dried in air, and pressed between two plates of Perspex or beryllium. The source was ^{57}Co in a chromium host. The spectrometer was conventional, and all but one of the spectra (Fig. 3*b*) were taken with a fly-back drive.

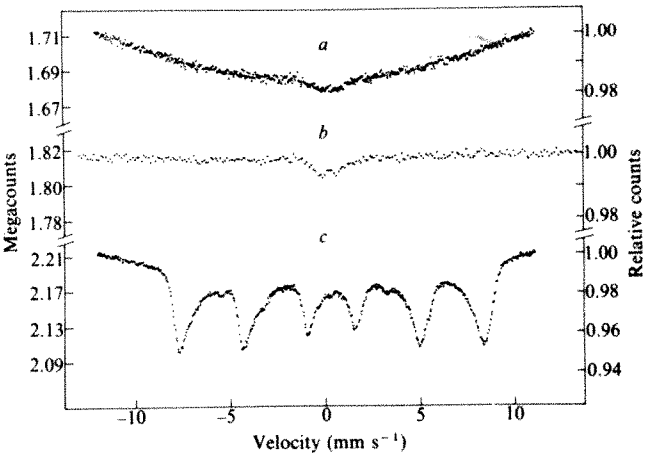

Fig. 3 Mössbauer spectra for aerosoled Fe particles subject to slow oxidation, sample B (238 Å). *a*, At 300 K; *b*, at 300 K, taken with a triangular waveform drive and folded; *c*, at 77 K.

Mössbauer spectra for samples A and B, both subjected to the slow-oxidation mode, are shown in Figs 2 and 3 respectively. An interesting and important feature is the lack of absorption at room temperature. Note that fine particles, close to or less than 100 Å in diameter but prepared by other methods, such as chemical precipitation, do display a central superparamagnetic absorption sometimes accompanied by hyperfine split patterns at $T = 300$ K. Therefore, the implication is that a majority of the ^{57}Fe nuclei in the aerosoled particles experience a recoil on absorption of the γ ray. Perhaps the iron atoms or ions are loosely bound within an aerosol particle, and further, any inter-particle interactions are relatively small. A weaker than normal binding would lead to a reduction in the Debye–Waller factor.

As the parabolic-shaped background introduces some ambiguity, a spectrum for sample B at 300 K was obtained with a triangular-shaped drive and a greater velocity range, and folded; it is shown as Fig. 3*b*. The small but non-zero central absorption shows that although the number of recoilless absorptions was

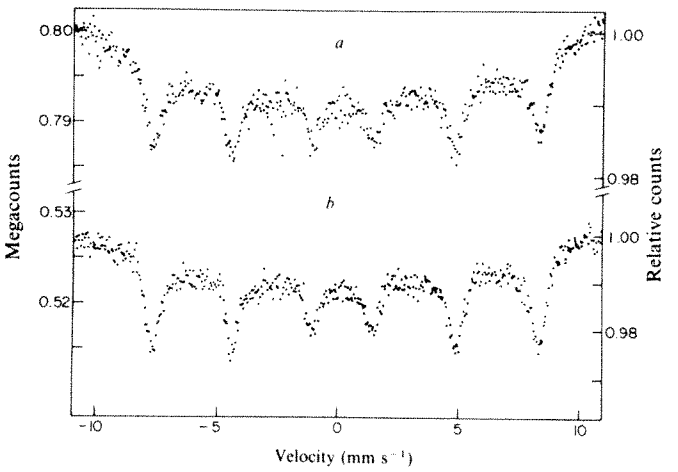

Fig. 4 Mössbauer spectra for aerosoled Fe particles subject to fast oxidation. *a*, Sample D (329 Å) at 300 K; *b*, sample E (366 Å) at 300 K.

small, the crystallites were in the superparamagnetic size range. This observation is fully compatible with the X-ray results.

In contrast, samples D and E, subjected to the fast-oxidation mode, exhibit hyperfine-split Mössbauer spectra at 300 K with, however, some reduction in the recoilless fraction as compared to bulk materials (Fig. 4*a*, *b*). When the temperature is elevated during the non-isothermal oxidation, not only do the oxide crystallites grow larger, but apparently the quality of crystallinity is also improved. Better developed crystallites would be expected to have strengthened atomic or ionic binding, and therefore a Debye temperature closer to that for the bulk.

In some situations, the Mössbauer effect can be used for phase analysis. By referring to standard spectra of α-Fe and the various iron oxides, the relative amounts of these phases can in principle be determined. By referring to Figs 2*b* and 3*c*, it is clear that both iron and iron-oxide phases are present. An earlier Mössbauer analysis of sample C established that the oxide is partially oxidised Fe_3O_4, possibly a mixture of stoichiometric Fe_3O_4 and γ-Fe_2O_3 (ref. 10). A similar situation seems to apply for samples A and B. The oxidised fractions of samples, A, B and C were determined from the 77 K spectra by comparing the areas of the oxide and metallic iron patterns employing computer fitting and assuming equal recoilless fractions for the two phases (Table 1). For samples D and E, the Mössbauer spectra confirm the X-ray analysis that the particles are almost entirely γ-Fe_2O_3.

Table 2 Hyperfine field at 77 K for aerosoled iron particles subject to slow oxidation

Sample	Hyperfine field (kOe)			Linewidth (mm s^{-1})		
	Fe	Inner sextet	Outer sextet	Fe	Inner sextet	Outer sextet
A	243	470	507	0.400	0.994	0.645
B	347	465	503	0.493	1.179	0.673
C	344	451	494	0.492	1.285	0.773
Micrometre-sized γ-Fe_2O_3*		508	525		0.562	0.533

One six-line pattern is assumed for metallic Fe and two six-line patterns are assumed for cubic iron-oxide.
* From ref. 25.

The hyperfine fields will now be discussed. In order to reduce the complexity of the analysis, the 77 K spectra of samples A, B and C were fitted with one six-line pattern for the iron and two six-line patterns for the iron oxides. This procedure is an over-simplification as the oxide is probably a mixture of γ-Fe_2O_3 and Fe_3O_4 in the Verwey state. The hyperfine fields and linewidths obtained are listed in Table 2. The iron hyperfine fields are close to the normal, bulk values, although the lines are somewhat broadened. However, the oxide's hyperfine fields are 30 to 50 kOe lower than those for micrometer-sized γ-Fe_2O_3 particles at 77 K. As a particle is made up of a central iron core covered with finely divided oxide crystallites, the magnetic moments of the oxide crystallites experience a considerable interaction at the iron interface. Then, the tendency towards superparamagnetic behaviour may be largely quenched at 77 K. However, fluctuations in the oxide's magnetisation direction may still be taking place, and if so, would lead to a reduction of the hyperfine field. This hypothesis is a modification of a collective magnetic excitation model proposed by Mørup and Topsøe[24]. In other words, the diminished value of the hyperfine field is an intrinsic size effect complicated by the exchange interaction at the iron interface.

Thus the oxidation mode used with ultrafine aerosoled iron particles profoundly influences the morphology of the oxide scales and the recoilless (Mössbauer) fraction. Some magnetic properties of these particles can therefore be controlled by the conditions of oxidation, and this feature should be of great utility in small iron particle applications.

A different genetic code in human mitochondria

B. G. Barrell, A. T. Bankier & J. Drouin*
MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK

Comparison of the human mitochrondrial DNA sequence of the cytochrome oxidase subunit II gene and the sequence of the corresponding beef heart protein shows that UGA is used as a tryptophan codon and not as a termination codon and suggests that AUA may be a methionine and not an isoleucine codon. The cytochrome oxidase II gene is contiguous at its 5' end with a tRNA^{Asp} gene and there are only 25 bases at its 3' end before a tRNA^{Lys} gene. These tRNAs are different from all other known tRNA sequences.

THE genetic code has been considered to be universal since the early work on *Escherichia coli* and mutant eukaryotic proteins. Once the code was established it was argued that any change would be lethal. This view was substantiated by the development of rapid RNA and DNA sequencing methods which have explored a wide variety of gene sequences that could be related to their protein sequences. We present evidence here, however, that mitochondria have an altered genetic code. This conclusion is based on the nucleotide sequence of a region of human mitochondrial DNA which was shown to code for an amino acid sequence homologous to the known protein sequence of the cytochrome oxidase subunit II (COII) of bovine mitochondria[1]. The homology was such that it was concluded that this region of the DNA was coding for the human COII gene. However, there were three TGA codons in the reading frame that was coding for the protein. This demonstrated that UGA was not acting as a termination codon. Moreover, the amino acid present in the bovine protein in all positions where TGA occurred in the human DNA sequence was tryptophan. Such a correspondence could only be satisfactorily explained if UGA was coding for tryptophan rather than for termination. Similar evidence is also presented that suggests that AUA is a methionine codon and not isoleucine.

Human mitochondria have a separate genetic system with a DNA genome of molecular weight 10×10^6. Figure 1 shows the organisation of the human mitochondria genome[2,3] aligned with the *Mbo*I restriction enzyme map. HeLa cell mitochondrial DNA (mtDNA) has been shown by hybridisation to code for a 12S and a 16S ribosomal RNA and at least 19 tRNAs[2-4]. HeLa cell mitochondrial translation products are less well defined and only cytochrome oxidase subunits I, II and III have been identified so far[5]. By analogy with other mitochondria systems (for review see ref. 6) genes for four proteins of the ATPase complex and one of the cytochrome bc_1 complex should also be present. However, it has become apparent recently that more proteins (at least 19) are coded for by HeLa cell mtDNA[7]. Both strands of HeLa cell mtDNA are completely transcribed symmetrically[8,9]. The rRNAs, the majority of the rRNAs and all but one of the polyadenylated RNAs hybridise to the heavy strand (H strand)[2,4,8,10]. Thus, the light strand (L strand) is defined as the main coding strand, having the same sequence as the rRNAs, tRNAs and mRNAs.

In the sequence of the COII gene region presented here we have identified two putative tRNA genes flanking the COII gene. A tRNA^{Asp} gene is 'butt-jointed' to the initiation codon of the COII gene, that is, there is no intercistronic space between them, and there are only 25 nucleotides between the termination codon of the COII gene and a tRNA^{Lys} gene. These tRNA genes are unusual in that they differ considerably in the 'D loop' and 'TψC loop' from all other known tRNA sequences.

DNA sequence analysis

*Mbo*I restriction enzyme fragments of human mtDNA obtained from a single term placenta have been cloned in the *Bam*HI site of pBR322 (ref. 42). Sequence analysis of clones pmt 110, 140 and 101, containing *Mbo*I fragments 6a, 15 and 6b, respectively (see Fig. 1), was by the chain termination method of Sanger *et al.*[11]. Single-stranded template DNA was prepared by the exonuclease III method of Smith[12]. By cleaving the duplex circular DNA at either the unique pBR322 *Hin*dIII site or the unique pBR322 *Sal*I site and digesting with exonuclease III, either strand of the region containing the inserted DNA was obtained pure for the primed synthesis DNA sequencing reaction. Small restriction fragment primers were prepared both from the pBR322 sequences flanking the insert, so as to prime into the insert from either side, and from within the insert.

The sequence determined is shown in Fig. 2. Sequence analysis of the *Alu*I restriction fragment spanning *Mbo*I fragment 15 which was cloned separately shows that there are no small *Mbo*I fragments between *Mbo*I fragments 6a, 15 and 6b (A. R. Coulson, personal communication). Two examples of chain termination sequencing gels are shown in Fig. 3. Figure 3*a* shows the sequence from −120 through the tRNA^{Asp} gene and

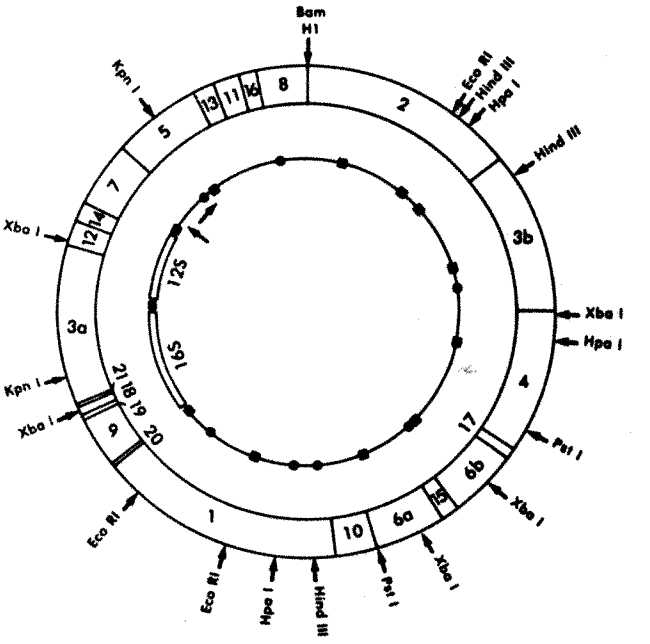

Fig. 1 The genetic map of the human mtDNA genome[2,3] is aligned with the *Mbo*I restriction enzyme map[42]. The precise order of fragments 21, 18 and 19 is not known. The sites of cleavage of some other enzymes are also shown[43,44]. The origin and direction of H-strand synthesis is shown[43,44]. The L-strand sequence 5' to 3' is anticlockwise and codes for the 12S and 16S rRNAs and tRNAs marked ■ (complementary to H strand). The H strand codes for the tRNAs marked ● (complementary to L strand). The COII gene is centred approximately on *Mbo*I fragment 15.

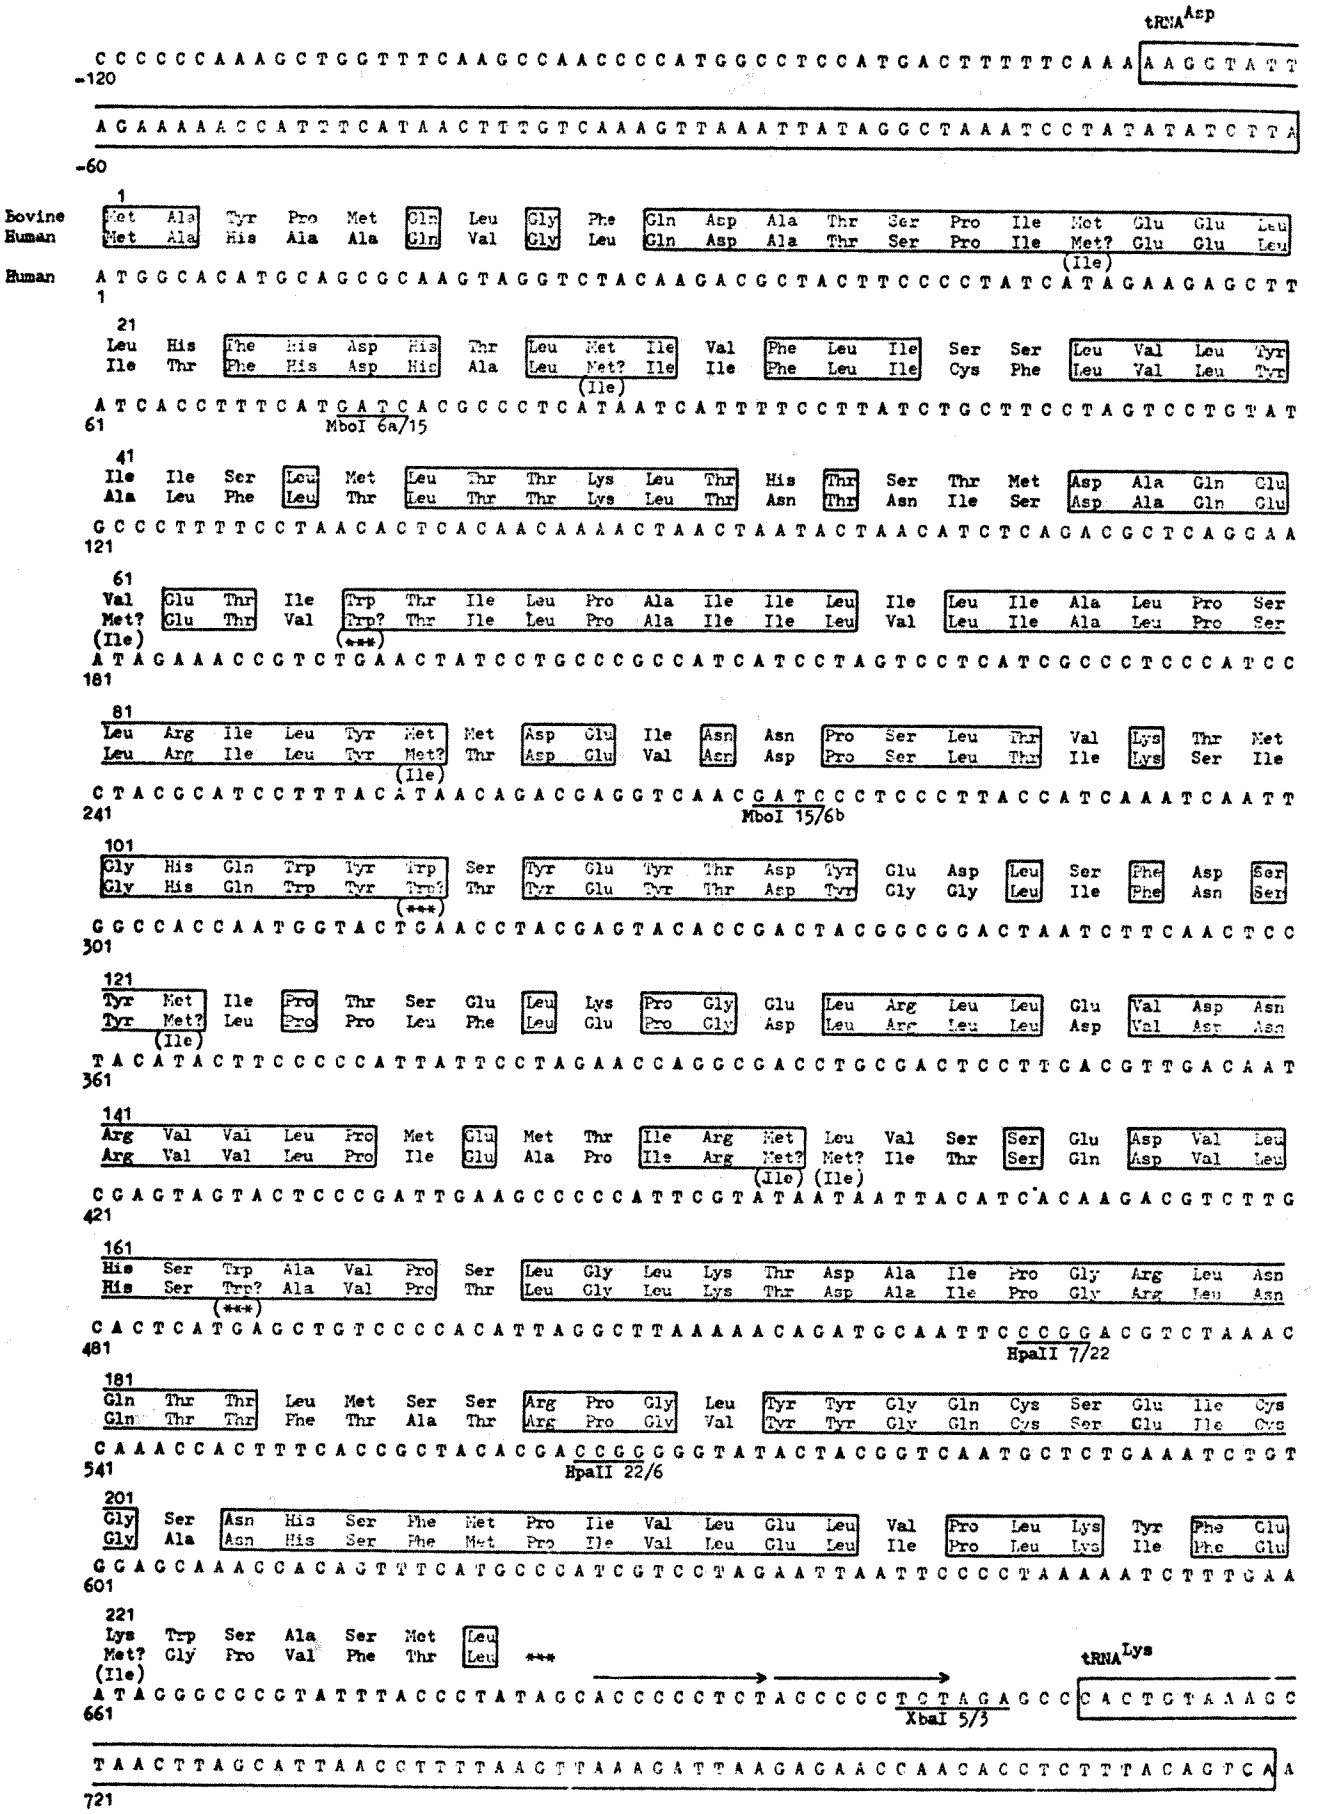

Fig. 2 The sequence of the COII gene region showing the position of the two tRNA genes and the COII DNA sequence aligned with the bovine COII protein sequence[1]. The predicted human protein sequence is compared with the bovine sequence and homologous amino acids are shown boxed using the codons AUA as methionine and UGA as tryptophan. Their normal assignments isoleucine and termination (denoted by ***) are shown underneath. The sequence can be aligned with the genetic and restriction maps shown in Fig. 1 by the restriction enzyme sites *Mbo*I and *Xba*I shown. A 9-base repeat at the end of the COII gene is also shown.

the beginning of the COII gene to the *Mbo*I site at position +73, and Fig. 3*b* shows the sequence obtained using *Hpa*II fragment 22 as a primer from position +521 to the *Mbo*I site at position +274. The positions of the TGA and ATA codons in these regions are shown.

tRNA genes

Three tRNA genes have been mapped in this region of the genome[2], two hybridising to the H strand and one to the L strand (see Fig. 1). In the sequence presented in Fig. 2 we have only been able to locate two tRNA genes, both of which are coded on the L strand, that is, the tRNA products would hybridise to the H strand. The locations of these tRNAs agree well with the hybridisation map positions[2] shown in Fig. 1, and from their positions in the sequence they probably correspond to H5 and H6 according to the nomenclature of Angerer *et al.*[2]. However, if this assignment is correct there should be a tRNA gene close to the $tRNA^{Lys}$ gene on the opposite strand that we have been unable to find. The tRNA genes were located by searching for base-paired cloverleaf structures using the computer programs HAIRPN[13] and TRNA (R. Staden, unpublished).

The sequences of the two putative tRNA genes are shown in the cloverleaf form in Fig. 4. If these tRNAs have CCA at their 3′ ends then this is not encoded in the DNA. The sequences in the D loop (left-hand loop) and the TψC loop (right-hand loop) of both tRNA genes differ considerably from the corresponding sequences found in all other tRNAs (see collection of 209 tRNA sequences compiled by Sprinzl *et al.*[14]). In the tertiary structure of yeast $tRNA^{Phe}$ (refs 15, 16) these two loops are hydrogen bonded together by conserved nucleotides not found in the two mitochondrial tRNA sequences. An examination of the primary structures of the two genes in these regions has not yet revealed how their respective D and TψC loops interact in the manner of yeast $tRNA^{Phe}$. A more detailed discussion of these and other human mitochondrial tRNA genes will be published separately.

UGA and UGG are both tryptophan codons in human mtDNA

The most interesting aspect of the sequence is in the part coding for the COII gene which is identified by the high homology with the bovine protein sequence[1]. When the human DNA sequence is aligned with the beef protein sequence as shown in Fig. 2, it becomes apparent that there are three 'in phase' UGA (*opal*) termination codons within the gene. The possibility that these are present in intervening sequences can be excluded by several criteria. First, the gene seems to be the exact length needed to code for its product, without interruption, from the AUG initiation codon to the UAG (*amber*) termination codon. Second, the UGA codons are in regions of very high homology between the beef and predicted human protein sequences. Finally, and most important, is the fact that they all align with tryptophans in the bovine protein. This suggests very strongly that UGA is a tryptophan codon in this genetic system and not a termination codon. There are five tryptophan residues in the bovine COII sequence, three of them opposite UGA codons, one opposite a UGG tryptophan codon and one opposite a GGG glycine codon. The latter is in a region where there is no homology with the bovine protein sequence at position 664 in the DNA sequence shown in Fig. 2. Tryptophan is normally coded for by a single codon, UGG, which is translated by a $tRNA^{Trp}$ with a CCA anticodon in both prokaryotes[17] and eukaryotes[18,19]. However, there is a precedent for UGA being used as a tryptophan codon. $tRNA^{Trp}$ from an *su*$^+$ UGA strain of *E. coli* (CAJ64) suppresses a UGA mutation in lysozyme mRNA during cell-free protein synthesis and synthesises polytryptophan from a repeating UGA polymer[20,21]. However, in both assays there was a low synthesis of product using $tRNA^{Trp}$ from the *su*$^-$ *E. coli* CA244. This, coupled with the observation that *in vivo* UGA codons are leaky in *su*$^-$ strains[22,23], suggested that the low level of UGA suppression in *su*$^-$ strains was caused by the normal $tRNA^{Trp}$. Also the low level of readthrough of the Qβ coat protein UGA termination codon in *su*$^-$ hosts was shown to occur by insertion of tryptophan and a functional longer protein necessary for infectivity was found in the phage particle[24,25]. Thus, there is a precedent in prokaryotes that UGA can be used as a tryptophan codon, albeit infrequently.

The codons UGA and UGG are adjacent in the genetic code (see Fig. 5) and could thus be recognised specifically by a $tRNA^{Trp}$ having the anticodon UCA according to the 'wobble hypothesis' (ref. 26) where U in the first position of the anticodon could pair with A or G in the third position of the codon. However, $tRNA^{Trp}$ from both the *su*$^-$ and *su*$^+$ UGA *E. coli* strains have CCA as their anticodons and the suppressor $tRNA^{Trp}$ has a G24 → A24 in the semi-invariant base pair in the 'D arm' (ref. 17). This must somehow alter the tertiary structure of the suppressor tRNA to allow the C in the first position of the anticodon to pair with the A in the third position of the UGA codon. Although neither the human mitochondrial $tRNA^{Trp}$ nor its gene has yet been characterised there is evidence from charging experiments[4] of unfractionated mitochondrial tRNA for a mitochondrially coded $tRNA^{Trp}$.

It thus seems clear that if this gene is expressed in its entirety, UGA and UGG are both used as tryptophan codons in the genetic code of human mitochondrial DNA. The sequence of the yeast mitochondrial COII gene also has UGA codons opposite tryptophan residues when it is aligned with the bovine COII protein sequence[27,41]. The use of UGA as a tryptophan codon would preclude the use of the cytoplasmic termination factor which corresponds to all three termination codons[28]. Prokaryotes use two factors, R1, which corresponds to UAA and UAG, and R2, which corresponds to UAA and UGA[29]. Thus, it is likely that the mitochondria has a factor analogous to R1.

Does AUA code for methionine in human mtDNA?

There are two codons in the genetic code that are each the sole codon for a single amino acid. The case of UGG for tryptophan has been discussed above. The other codon is AUG, which codes for methionine, and in the same box isoleucine is encoded by AUC, AUU and AUA. All other boxes can be read using G–U wobble[25] by one tRNA that is specific for codons ending in C and U and another that is specific for codons ending in A and G. The main exception to this is when the anticodon contains modified bases that can restrict the coding properties. Thus, with the UGA/tryptophan precedent in mind, can AUA code for methionine? There are 15 internal methionine residues in the beef COII sequence and only one of these is aligned with an AUG codon but five of them are aligned with AUA codons (Fig. 2). There are eight AUA codons, five aligned with methionine, one with valine, one with leucine and one with lysine. None is aligned with isoleucine codons. Thus, there are two possibilities: either by coincidence the bovine methionine residues in these positions are being preferentially replaced by isoleucines which are all coded for by AUA, or there is another change in the code and AUA is being recognised as a methionine codon. AUA and AUG could both be recognised by a tRNA having the anticodon UAU according to the wobble hypothesis[26].

In view of the UGA/UGG precedent we think that the above data suggest that AUA and AUG are methionine codons. However, isoleucine and methionine are both hydrophobic amino acids and confirmation will depend on the determination of the human COII protein sequence.

If it is assumed that AUA is a methionine codon and UGA a tryptophan codon, the bovine protein and the predicted human protein sequences are 72% identical. The conserved amino acids are shown boxed in Fig. 2. This leaves 62 out of 227 amino acids in bovine COII that are different in the human COII. It is striking that 22 of these differences involve either methionine or serine aligning with other amino acids, eight of them threonine, using the codons ACA and ACC. However, both of these codons also align with threonine, and with the data shown in

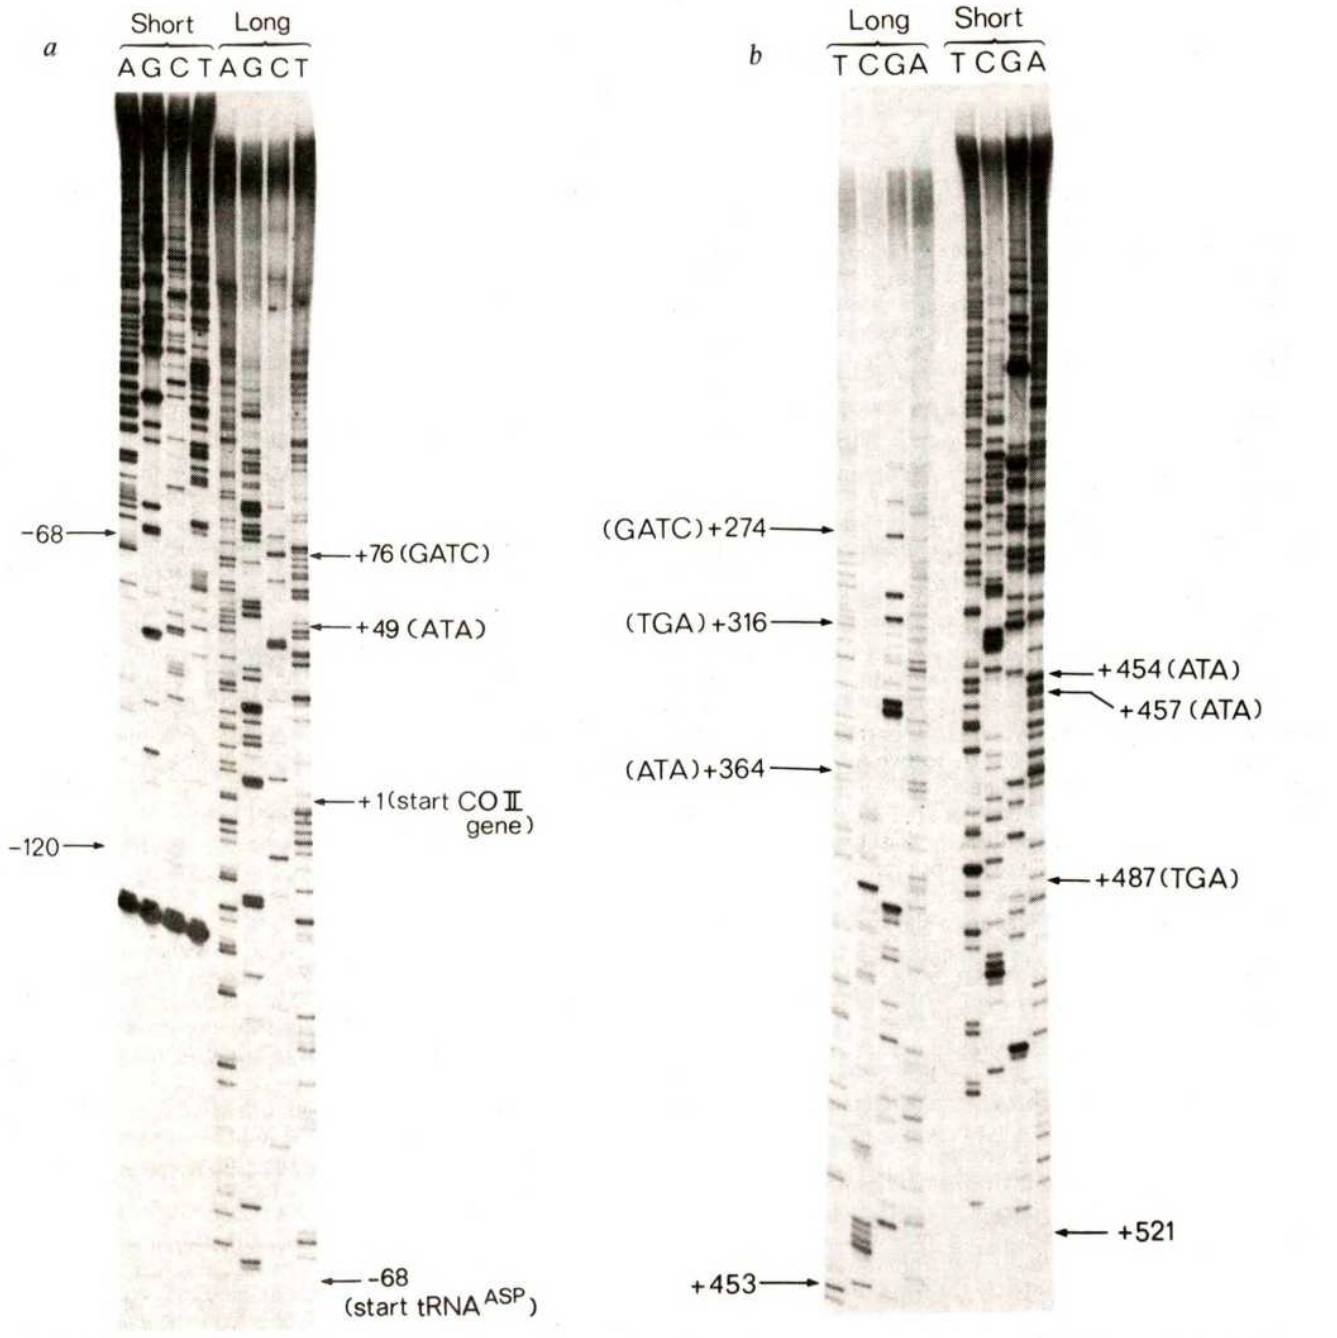

Fig. 3 Two examples of chain termination sequencing gels in the COII gene region. *a* Shows the use of a small restriction fragment primer in *Mbo*I fragment 6a primed on 'H-strand' template prepared from clone pmt 110 (see text) by the exonuclease III method of Smith[12]. The sequence corresponding to that given in Fig. 2 can be read from base −120 to the *Mbo*I site at +76 which is the junction between the clone of *Mbo*I 6a and pBR322. The starts of the $tRNA^{Asp}$ gene and the COII gene are shown along with the ATA codon at position +49. A short run and a long run of the sequencing reactions on the same 8% polyacrylamide thin gel[46] are shown. *b* Shows a similar experiment using the fragment *Hpa*II 22 as a primer on 'L-strand' template prepared from clone pmt 110 (*Mbo*I fragment 6b, see text). For ease of reading the track order A, G, C, T has been changed to the complementary order T, C, G, A so that the gel can be read as the L-strand sequence 5′ to 3′, from top to bottom. The sequence from the junction between pBR322 and *Mbo*I 6b at position +274 can be read to position +521. The positions of the UGA and AUA codons are shown.

Fig. 2 there is no clear indication of other coding changes. The one difference between the yeast mitochondrial ATPase subunit 9 protein sequence[30] and the sequence of its gene[31] is a threonine aligned with a CUA codon. In the human COII gene, 11 out of 12 CUA codons align with leucine so that this cannot be a coding change in human mtDNA. However, it is possible that other coding changes will be found in mtDNA and there may be different codes in the mitochondria of different species.

Codon usage in the COII gene

Figure 5 shows the suggested code in human mitochondria with AUA as possibly methionine and UGA as tryptophan. The number of times each codon appears in the COII gene is also shown. All amino acids are used and nearly all codons. Only one of the serine AGU/C set is used and none of the arginine AGA/G set. Excluding the UAG termination codon, only 16 out of 227 codons end in G. This reflects the low G content found in the L strand generally (unpublished results). Specifically in this region the composition is A, 29.9%; C, 30.2%; T, 25.8% and G, 14.1%. The low G content may be of significance when considering the evolution and use of the coding changes proposed here. Including AUA as methionine and UGA as tryptophan the ratio of codons ending in A to those ending in G is 5:1.

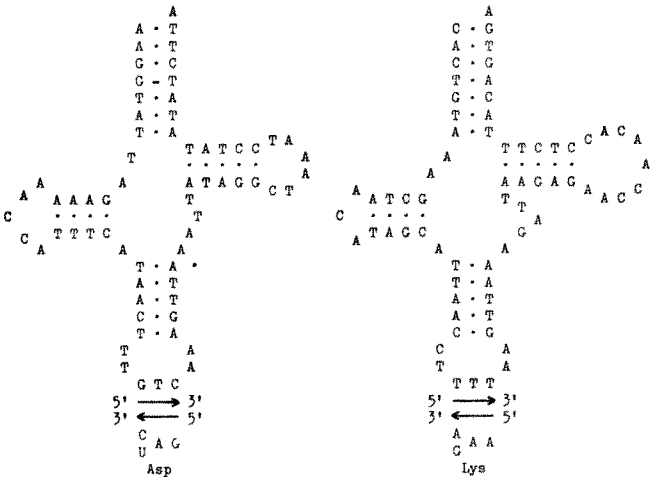

Fig. 4 The DNA sequences of the $tRNA^{Asp}$ and $rRNA^{Lys}$ genes are shown arranged in the cloverleaf conformation. The CCA sequence found at the 3′ end of all tRNAs is not encoded in the DNA sequence. The presumed codons that these tRNAs would recognise by G–U wobble[26] are indicated.

It is also interesting to consider the codon usage in relation to the number of tRNAs found to be encoded by human mtDNA. The highest number of tRNAs so far found to be coded by mammalian mtDNA is 21 (ref. 32) out of the minimum number required using G–U wobble of 32. If the AUA coding change is substantiated then a minimum of 31 would be required. On the basis of the relatively small sample of codons of the COII gene, it is probably reasonable to assume that in the whole genome all codons are used, although some may be used rarely. There is no evidence in mammalian mitochondria to suggest that any RNA is imported, and so there may be a complete set of mitochondrially coded tRNAs. Otherwise, it is difficult to see how 21 tRNAs could recognise all codons without some degree of misreading. However, it is possible that the smaller rRNAs, the novel features of the tRNAs, the possible coding changes discussed here and a limited set of tRNAs might indicate that a different protein synthesis decoding mechanism operates in the mitochondria. Selective use of a 'two out of three mechanism' (refs 33, 34) would only require 23 or 24 tRNAs, depending on the coding changes.

Organisation of genes in the COII region

Attardi *et al.*[7] discussed two models for the organisation of the tRNA genes with respect to the protein coding sequences. As can be seen in Fig. 1 the tRNA genes are scattered more or less uniformly around the genome and on both strands. These genes could either separate the sequences coding for the mRNA (the punctuation model) or could reside in them in the manner of intervening sequences (the insert model). The COII gene is flanked by two tRNA genes as shown in Fig. 2 but surprisingly, the $tRNA^{Asp}$ gene is actually contiguous with the COII gene, with no noncoding nucleotides in between. Thus, it is possible that if there are sequences involved in ribosome recognition preceding the initiation codon these lie in the $tRNA^{Asp}$ gene. No sequence corresponding to the *E. coli* ribosome recognition site is found[35,36]. There is a sequence similar to that postulated to have the same function in eukaryotes[37] but there is no evidence that this interaction occurs in eukaryotes and in any case mitochondria have their own rRNAs, which are much smaller than both their prokaryote and eukaryote counterparts. The possibility of a leader peptide which is subsequently processed is ruled out by in-phase UAA termination codons preceding the initiation codon.

The contiguous nature of the two genes raises the obvious difficulty in processing the primary transcript. Both strands of the mtDNA have been shown to be completely transcribed and it is not known whether there are additional promoters. If a full length transcript of the H strand is processed to give the rRNAs, and the tRNAs and mRNAs, the latter being polyadenylated at some stage, then a single cleavage between the two genes would leave no 5′-leader sequence on the COII gene mRNA. Therefore, if initiation of translation of the COII mRNA required signals in the sequence preceding the initiation codon, the tRNA would either have to be released after the cessation of translation of the mRNA or have to be transcribed separately. An intriguing possibility is that the tRNA could be spliced out of the transcript in the manner of an intervening sequence, although this seems unlikely; no evidence has yet been found for intervening sequences in human mtDNA.

There is a short noncoding region (25 bases) between the end of the COII gene and the $tRNA^{Lys}$ gene and this contains a 9-base repeat, as shown in Fig. 2. The sequence AAUAAA is presumed to be involved in polyadenylation of eukaryotic mRNAs and the nearest is 224 bases downstream of the 3′ end of the COII gene (unpublished results). If this is the signal for polyadenylation of the COII mRNA, a similar problem to that of the $tRNA^{Asp}$ regarding the processing of the $tRNA^{Lys}$ arises.

There has been considerable speculation that mitochondria have evolved from bacteria that had entered into a symbiotic relationship with their host (for review see ref. 6). The economical use of the coding capacity of the DNA is more characteristic of prokaryotes, in particular bacteriophage DNAs such as ΦX (ref. 38), but the eukaryotic viruses such as SV40 (refs 39, 40) show similar economy. Thus, it is difficult to draw any conclusions as to whether this genetic system is more similar to prokaryotes or eukaryotes on this basis. If the endosymbiotic theory is correct, the different genetic code may represent a 'frozen', more primitive code, for it is unlikely that once mitochondria became essential to their 'host' the code would be able to change. Whatever their origins the novel features of the mitochondria discussed here seem to require that they be considered a separate class from the prokaryotic and eukaryotic genetic systems.

Since this paper was submitted, Macino *et al.*[41] have also demonstrated the use of UGA as tryptophan in the yeast mtDNA COII gene. Also, recent work by F. Sanger and A. R. Coulson (personal communication) has identified the sequence coding for the tryptophan tRNA gene in human mtDNA. As predicted, this structure has the anticodon UCA which would pair with UGA and UGG using G–U wobble.

We thank Dr G. Buse for communicating to us the bovine COII protein sequence before publication, and Drs F. Sanger and J. E. Walker for advice and helpful discussions.

Where can antimatter be hidden in the Universe?

Yu. A. Beletsky, A. I. Bugrij, E. S. Martynov & A. A. Trushevsky

Institute for Theoretical Physics, Academy of Sciences of the Ukrainian SSR, Kiev 130, USSR

Undoubtedly complete symmetry of charge in the initial state of the Universe is an attractive idea. However, analysis of observational data[1] indicates that the visible Universe contains mostly particles of positive baryon number. Attempts[2–6] to reconcile the assumption of initial symmetry with this observed asymmetry have met with some difficulties. However, if one accepts that the Universe is symmetric in baryon charge, then there must be regions of space or objects which contain at least as much antimatter as the matter which we observe. We propose here that the hypothesis of primordial black holes (PBHs)[7,8] offers a simple and economic solution of the problem. Because of the well-known 'no hair' theorems the baryonic charge of PBHs cannot be observed, and hence PBHs are ideal stores for antimatter.

Extra antibaryons can be captured by PBHs either because of fluctuations in the density of the baryonic charge[9] or for dynamic reasons. Here we concentrate on the first possibility: we assume that in the early Universe the PBH happened to collect excess antibaryons. Then, after baryon–antibaryon annihilation we arrive at the present charge asymmetry.

To obtain some quantitative estimates we assume that in the hadronic era M black holes were created each containing N_i^+ baryons and N_i^- antibaryons and that their distribution in the ith PBH ($i = 1, 2, \ldots, M$) is the gaussian

$$W(N_i^{\pm}) = (2\pi\overline{\Delta N_i^2})^{-1/2} \exp\{-(N_i^{\pm} - \bar{N}_i)^2/2\overline{\Delta N_i^2}\} \quad (1)$$

The mean number of particles $\bar{N}_i$ and the fluctuations $\overline{\Delta N_i^2}$ are taken to be equal for particles and antiparticles because of the charge symmetry of the strong interaction. The probability that the PBH contains N_u extra antibaryons is

$$W(N_u) = \int_0^{\infty} \left\{ \prod^{M} \frac{dN_i^+ \, dN_i^-}{2\pi\overline{\Delta N_i^2}} \exp\left[-\frac{(N_i^+ - \bar{N}_i)^2 + (N_i^- - \bar{N}_i)^2}{2\overline{\Delta N_i^2}} \right] \right\}$$

$$\times \delta\left[\sum_{i=1}^{M} (N_i^- - N_i^+) - N_u \right] \quad (2)$$

$$= \left(4\pi \sum_{i=1}^{M} \overline{\Delta N_i^2} \right)^{-1/2} \exp\left(-\frac{N_u^2}{4\sum_{i=1}^{M} \overline{\Delta N_i^2}} \right)$$

Equation (2) shows that the most favourable situation corresponds to a minimum (mean) asymmetry of black holes: the greater the mass contained in a PBH (the more it increases $\sum^M \overline{\Delta N_i^2}$), the larger is the deviation.

Let us now estimate the maximum energy density (averaged over the whole of space) of unobservable forms of matter assuming the present value of the Hubble constant H and that the age of the Universe ($\sim 2 \times 10^{10}$ Myr) exceeds the age of the Earth ($\sim 5 \times 10^{9}$ Myr). This gives

$$Ht \leq f(\Omega)$$

where $\Omega = \rho/\rho_c$ is the ratio of the energy density of the whole matter to the critical density, and $f(\Omega)$ for the closed Universe has the form

$$f(\Omega) = \frac{\Omega}{(\Omega-1)^{3/2}} \left[\arcsin\left(\frac{\Omega-1}{\Omega}\right)^{1/2} - \left(\frac{\Omega-1}{\Omega}\right)^{1/2} \right]$$

0028–0836/79/450194—02$01.00

© 1979 Macmillan Journals Ltd

It follows that

$$\Omega \leqslant 62.5$$

As the density of observable forms of matter $\rho \approx 0.03\rho_c$, then the ratio of the energy density of unobservable to observable forms of matter can reach 2×10^3 and, consequently, the mean asymmetry in PBH is $\sim 5\times10^{-4}$.

If matter in its early stages can be considered as an ideal gas, then $\Delta N_i^2 \sim N_i$ and the probability $W(N_u)$ for N_u baryons in the Universe will be

$$W(N_u) \sim \exp\left\{-\frac{N_u^2}{N}\right\} = \exp\{-\sigma N_u\}$$

where σ is a measure of the asymmetry in PBHs. As should have been expected, an asymmetric creation of PBHs is highly unlikely. Nevertheless 'the dice were cast only once', which gives us the opportunity to analyse the evolution of the Universe.

Note that the possibility for an asymmetric creation of PBHs can be considerably increased if matter at the early stage satisfies a non-ideal equation of state. For example, for van der Waals equation the free energy has the form[10]

$$F = -NT\ln\frac{eVn_0(T)}{N} - NT\ln\left(1-\frac{Nb}{V}\right) + a^2\frac{N^2}{V}$$

and

$$\overline{\Delta N^2} = T\left(\frac{\partial N}{\partial \mu}\right)_{V,T} = T\left(\frac{\partial^2 F}{\partial N^2}\right)^{-1}_{V,T} = \left[\frac{V^2}{N(V-Nb)^2} - \frac{2a}{TV}\right]^{-1}$$

Hence in the vicinity of a phase transition, $\overline{\Delta N^2}$ may become arbitrarily large and make the capture of extra antibaryons in PBHs probable. A van der Waals system of ultrarelativistic particles has been considered in detail elsewhere[11].

Note also, that this probability makes sense either when an ensemble of systems is indicated or when the event is repeated in time. Therefore, for the Universe as a whole it should be used with care. Of course, one can assume (without any hope of confirmation) that there are many universes which like ours originated in a big bangs; we then live in 'the best of all worlds': in the world in which a fraction of the antimatter has been hidden in PBHs. Another possibility concerns an oscillating Universe, in which expansions are followed by collapses. In this case we should have to wait for the situation described above to be realised (with the formation of asymmetric PBHs).

The account of the evaporation of black holes given by Hawking[12] does not essentially change the situation; it only imposes limitations on the mass spectrum of PBHs[13]. Moreover, as the evaporation of black holes is a charge-symmetric process, the extra baryonic charge captured by PBHs will not be observable, even if the evaporation ceased and created a naked singularity, the maximon[14].

Structure of the uranian upper atmosphere

J. Churms*, J. L. Elliot† & E. Dunham†

* South African Astronomical Observatory, C.P., Republic of South Africa
† Department of Earth and Planetary Sciences, and Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

Although the occultations of relatively bright stars by planets are rare events, they provide an important ground-based method for determining temperature, pressure and number density profiles of planetary upper atmospheres[1]. The technique is particularly valuable for planets in the outer Solar System, whose atmospheres have not yet been probed by spacecraft missions. Since the atmosphere of Uranus had not yet been investigated by the occultation technique, we have observed and report here the occultation of the star SAO158687 by Uranus on 10 March 1977 (refs 2, 3).

A photometer was set up on the 0.46-m reflector at the Cape Observatory, South Africa that used an RCA photomultiplier with a gallium arsenide photocathode, and a 3-mm thick Schott RGN9 filter. The data were recorded on one channel of a chart recorder, while radio time signals were recorded on another channel. The time constant of the data recording system was ~3 s and the signal from the star produced a deflection of 1.0 cm on the chart. The chart was measured at intervals of 0.5 s.

The light curves were analysed using the inversion method of French, Elliot and Gierasch[4]. This procedure gives the number density, pressure and temperature of the occulting atmosphere as well as the uncertainties in these values due to shot noise in the light curve. The derived temperature profiles for immersion and emersion are plotted as a function of number density in Fig. 1. The shaded upper section represents an isothermal atmosphere fit to the initial part of the light curve, which provides definite initial conditions with which to begin the numerical inversion calculation. The inversion was terminated when the uncertainty in the baseline of the light curve produced an error in the temperature equal to the shot noise error. The error bars in Fig. 1 have a total length of two standard deviations, and represent the uncertainty in the overall placement of the profile at that point. The small scale structure is more reliable than the overall placement of the curve because the error in the placement of successive points is strongly correlated[4,5].

The fundamental quantity obtained from the inversion is the scale height H which is related to the temperature T of the atmosphere, through the equation $T = \mu gH/R$, where μ is the mean molecular weight of the atmosphere, g is the local gravitational acceleration and R is the universal gas constant. To establish the temperature scales in Fig. 1 we assumed $g = 830\ \mathrm{cm\ s^{-2}}$ and $\mu = 2.2\ \mathrm{g\ mol^{-1}}$, which corresponds to an atmosphere of H_2 and He in their solar abundances. If this assumption about the composition is wrong, the scale heights in Fig. 1 will not be affected, but the temperature scales will have an error proportional to the ratio of the true mean molecular weight to that assumed here.

The mean temperature of the inverted section of the profile is 87 K for immersion and 90 K for emersion. The temperature derived by fitting an isothermal atmosphere occultation light curve[6] to the data is 104 K for immersion and 108 K for emersion. Because the atmosphere is strongly non-isothermal, we feel that the mean inversion temperature should be a more reliable indicator of the mean atmospheric temperature than the isothermal fit temperature.

© 1979 Macmillan Journals Ltd

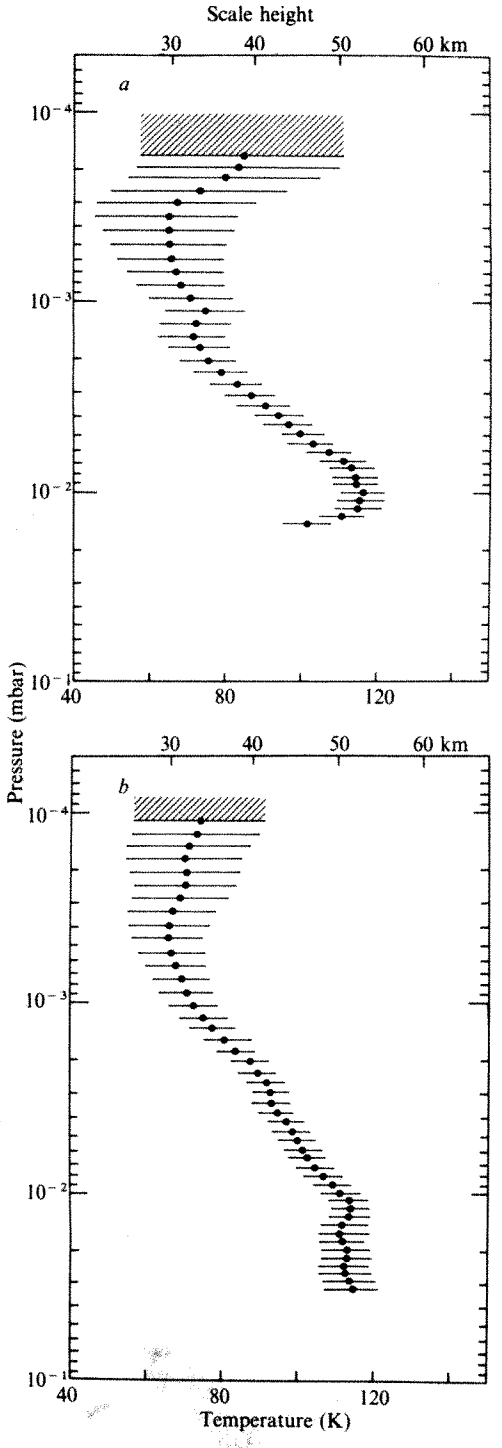

Fig. 1 Temperature profiles of the uranian upper atmosphere for: *a*, 7° N lat, Cape Town immersion; and, *b*, 21° S lat, Cape Town emersion. The shaded areas are the regions of the isothermal fit boundary condition. The level at half light is indicated on the right, while the temperature from a full isothermal fit is indicated at the bottom. Note the large variations in temperature.

At the time of the occultation, the subsolar point on Uranus was located at latitude +51.0° and the phase angle was 2.4°. The immersion and emersion points as seen from the Cape were at latitude 7.3° N and 20.9° S respectively, with immersion occurring just before sunrise and emersion just after sunrise. Our results indicate no large difference in the mean temperature for these two conditions.

Both temperature profiles show large variations, ~50 K peak-to-peak for immersion and 40 K for emersion, with a vertical length scale of ~150 km. Although some of this variation is probably due to noise, we believe that most of these variations represent real temperature variations in the atmosphere of Uranus. First, they are much larger than any variations one might expect from shot noise in the light curve[4] and second, the profiles agree well with the Kuiper Airborne Observatory (KAO) results[7,8]. The regions of the uranian atmosphere probed by observations from the Cape and the KAO correspond to the same levels in the atmosphere, but are displaced from each other about 2,200 km along the limb of Uranus for the immersion data and 2,600 km for the emersion data.

The mean atmospheric temperature found here (~90 K) is somewhat cooler than the 140 K found for the upper atmosphere of Neptune from a previous stellar occultation[9]. It is also cooler than that obtained by Wallace[10] from model calculations. Further work will be required to find the reasons for these differences and to establish the cause of the observed 'wavelike' temperature variations. The main problem with dynamical explanations for the wavelike structures is that the obvious wave mechanisms—vertically propagating density waves, for example—apparently heat the atmosphere to much higher mean temperatures than we observed[8]. A more likely possibility is that the variations are caused by photochemical processes[8].

The data analysis for this work was supported in part by grant AST-7908376 from the NSF. J.C. thanks P. J. Booth for valuable assistance.

Multiply-twinned particles in silver catalysts

L. D. Marks & A. Howie

Cavendish Laboratory, University of Cambridge, Madingley Road, Cambridge, UK

It has been known for several years that anomalous structures can occur in the early stages of particulate growth. Ino[1] and Ino and Ogawa[2] for gold on rocksalt and Allpress and Sanders[3] for nickel on mica found small polycrystalline nuclei which they interpreted as multiply-twinned particles (MTPs). These particles can be considered as 5 or 20 f.c.c. tetrahedra joined by twin boundaries to give decahedra or icosahedra (Fig. 1). As the tetrahedra do not assemble to a completely space filling structure, either elastic strains or grain boundaries are required to complete the particles. More recently, MTPs have been observed in the early stages of growth for all f.c.c. metals in certain conditions. Gillet[4] has recently reviewed the field whilst Hayashi *et al.*[5] give extensive results for f.c.c. metals in argon smokes. The possible significance of MTPs in heterogeneous catalysts was first suggested by Allpress and Sanders[6] and investigated by Avery and Sanders[7]. They found, however, that at most 2% of particles 100–350 Å in size for Ni, Au, Pt and Pd on γ-alumina were multiply twinned. We report here the presence of considerable numbers of multiply-twinned particles in various heterogeneous metal catalysts, in particular silver on α-alumina. The particles can have quite large dimensions up to ~2,000 Å. Attention is drawn to the possible significance of some special sites on these particles which have no counterpart on single crystal surfaces, and to the unusual distribution of surface faces.

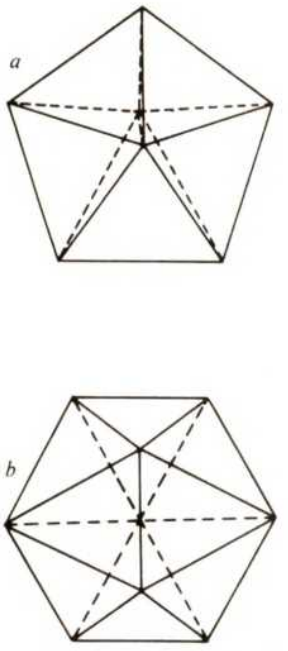

Fig. 1 Structure of *a*, decahedral and *b*, icosahedral multiply-twinned particles.

The samples examined were supplied by ICI Ltd, having been prepared by the following method (UK Patent 1369639): an $0.8\,M^2g^{-1}$ support of α-alumina (Carborundum Ltd, No. SAHT96) was immersed in a solution of silver oxalate in 45% water—45% ethylene diamine—10% ethanolamine. The support was then pyrolysed in nitrogen at 200 °C for 1 h to decompose the oxalate to silver metal. The catalyst examined contained approximately 16% silver by weight. Samples were prepared for examination in a Siemens 102 microscope by allowing a drop of ground catalyst suspended in acetone to dry on amorphous carbon films premounted on microscope grids.

The samples examined contained principally isolated particles of size between 1,000 and 2,000 Å, although smaller particles (<500 Å) were found associated with amorphous regions of the substrate, and a few large polycrystals were observed, presumably due to particle coalescence. The discrete particles displayed well developed 111 facets, with very little edge or corner rounding. More than 80% of the discrete particles were observed to be MTPs, the remainder being composed mainly of twinned platelets, faulted needles and single crystals. Micrographs of these various morphologies are shown in Figs 2 and 3. All the icosahedral MTPs and most (but not all) of the decahedral MTPs displayed internal contrast suggestive of dislocations, as has been previously noted for large MTPs[8].

The occurrence of MTPs in heterogeneous catalysts is consistent with their common observation in epitaxial films. MTPs may well occur in many other catalysts; we have, for example, examined micrographs of a nickel catalyst (A. Szczepura, personal communication) which show contrast typical of MTPs. The apparent contradiction between our results and those of Avery and Sanders[7] is probably due to the different methods of production; the particles described here were prepared by a mild pyrolysis, whereas Avery and Sanders examined their particles after annealing in hydrogen. Preliminary results for <50 Å gold particles on NaCl or amorphous Al_2O_3 have shown that the particles are single crystals after annealing at 500 °C in hydrogen but multiply twinned after annealing at 500 °C in air. It seems probable that the occurrence and survival of MTPs in catalysts may depend on the atmosphere present during both preparation and running.

The large sizes of the MTPs observed is probably a result of the growth conditions. As the type of particle observed corresponds with the types commonly found for small (<200 Å) metal particles, it seems likely that the internal structure was determined at some early stage in the growth. Further layer growth, possibly autocatalytic in nature, could produce the observed particles. In the absence of sufficient activation energy from processes such as coalescence, the particles can remain in the multiply twinned structure, even though this is almost certainly metastable in this size range. Given the existence of the multiply twinned structure, the equilibrium of the surface faceting is an additional question. More detailed experimental and theoretical studies of this problem, which will be published elsewhere, suggest that the form observed here, with sharp 111 facets, may in fact be metastable with respect to surface changes at room temperatures and that the stable structure would have additional 100 facets as well as notches at the boundaries.

One interesting feature of the MTP is that they have some unusual surface sites, some of which have no analogue on a single crystal surface. On the actual twin boundary the atoms have h.c.p. coordination rather than f.c.c. so that the *d*-bonds will be differently orientated. Also, as mentioned above, more complicated faceting geometries including notches may arise if the surfaces attain their equilibrium configuration. Such notches or re-entrant surfaces have been considered to act as preferential nucleation sites for crystal growth[9] and may have some catalytic importance. For a 50-Å radius particle approximately 7% of the surface atoms would be on the twin boundaries, a third of these at the notches.

Anomalous surface sites associated with twins are, of course, also found in other particles. Re-entrant surfaces have been observed for f.c.c. particles with an odd number of closely spaced parallel twin boundaries by Hayashi *et al.*[5]. However, the twin density in MTPs will usually be higher than in other particles.

The fact that MTP surfaces will usually consist of a different distribution of crystal faces than would occur in a single crystal could also be of significance in catalytic reactions which are sensitive to surface crystallography. It seems likely that MTPs will have an anomalously high fraction of their surface as (111) planes and, in addition, the icosahedra will not have any (100) surface planes.

Because the tetrahedral units are not completely space-filling the MTPs probably contain considerable elastic strain, or possibly crystal defects such as dislocations as observed in Si particles by Saito[8]. In either case the catalytic properties may be

affected. Ino[10] assumed a homogeneous elastic strain maintained by external forces to estimate the elastic strain energy using anisotropic elasticity theory. His figures for Ag indicate that the lattice parameters in the surface of the icosahedron are expanded by about 3%, while the spacing of planes parallel to the surface is reduced by nearly 5%. The lattice parameter in the surface of the decahedron is increased by 1% in the direction of the ⟨110⟩ outer perimeter and reduced by 1% in the direction normal to this. Removal of Ino's external forces will lead to additional inhomogeneous elastic strains. De Wit[11], for instance, has pointed out the similarity between the decahedron and a disclination which has very high compressions close to the central axis. In the icosahedron the stress is probably also inhomogeneous, being highly compressive at the centre and tensile at the surface. More detailed calculations have been made but these are complicated by the uncertain effects of surface tension stresses in such small particles (A.H., L.D.M. and E. H. Yoffe, in preparation).

Clearly it would be of considerable interest to produce catalyst samples containing, for example, a larger proportion of single crystal particles in the same size range as the MTPs. It might then be possible to make a direct experimental assessment of the practical significance of these anomalous structures in catalysis.

We thank Dr R. W. Clayton (ICI) for supplying catalyst samples and for useful discussions, and the SRC for a CASE Studentship (L.D.M.) and for a grant supporting the electron microscopy of catalysts.

Propagating chemical waves in the uncatalysed gallic acid–bromate system

K-W. Pehl, L. Kuhnert & H. Linde

Zentralinstitut für physikalische Chemie, Akademie der Wissenschaften der DDR, 1199 Berlin, Rudower Chaussee 5–6, DDR

Chemical oscillatory systems which include at least one autocatalytic reaction step are of interest as thermodynamically open systems in which temporal and spatial structures are produced. These systems also show other types of unusual kinetic behaviour[1]. To analyse the elementary steps of their kinetics the simplest possible reactions are needed especially in relation to nonlinear thermodynamics[2]. The theory of these chemical reactions is still only at the level of a simplified mathematical model, and theoretical results are in poor agreement with experimental findings. Therefore it is important to study other examples of spatial dissipative structures corresponding to chemical systems which exhibit oscillations. We report here observations of the oscillating reaction between bromate and the phenolic compound gallic acid in which propagating chemical waves occur.

The Belousov–Zhabotinskii reaction system (BZR) is known to exhibit propagating chemical waves[3]. This reaction is very complex and involves about 20 elementary steps (the mechanism has been elucidated by Field *et al.*[4]) starting from an initially homogenous state. Until now no other chemical reaction starting from this condition has been found to form a spatial structure spontaneously (unlike a Liesegang ring-type one).

The BZR requires a transition metal catalyst but the rate law of wave propagation shows the propagation velocity to be independent of the concentration of the catalyst in the range studied by Noyes and Field[5]. This means that the step catalysed by the transition metal ion, although necessary for oscillation and/or wave propagation in the BZR does not determine the propagation velocity.

Körös and Orban[6] have reported a new oscillatory chemical reaction between bromate and phenolic or aniline-type compounds, occurring in the absence of a catalyst. (A catalyst may be added, but the reaction then becomes of the normal BZR type[7,8].) A similar reaction between bromate, and bisazonium salts was reported previously by Kuhnert and Linde[7].

Our experiments were carried out at room temperature in Petri dishes using a solution volume of 11 ml to give a layer ~1 mm deep. As the waves were hardly visible in daylight, they were observed and photographed under filtered blue light from a high-pressure mercury discharge lamp. The light intensity selected was low enough to prevent photochemical excitation of the reaction mixtures (formation of bubbles).

The reaction solutions were prepared in the following way. Mixtures of 7 ml of distilled water, 3 ml of sulphuric acid (4 M), and 1 ml of a solution of sodium bromate (1.5 M), were stirred and saturated with gallic acid; excess gallic acid was filtered off rapidly, and the filtrates were poured into Petri dishes. Reaction times were measured from when components were mixed. The brown solutions rapidly turned pale but darkened again slowly. After periods of 3 to 10 min colourless waves started propagating with a speed of 2 to 4 mm per minute from leading centres commonly situated at the borders of the dishes. In most experiments several leading centres appeared, and when the waves propagating from them came into contact, destructive interference was observed. Artificial leading centres could be created by adding droplets of concentrated sodium bromate solution to the reaction mixtures, these leading centres exhibited the same behaviour as the original ones, but often generating waves of shorter wavelength. Wave propagation was generally

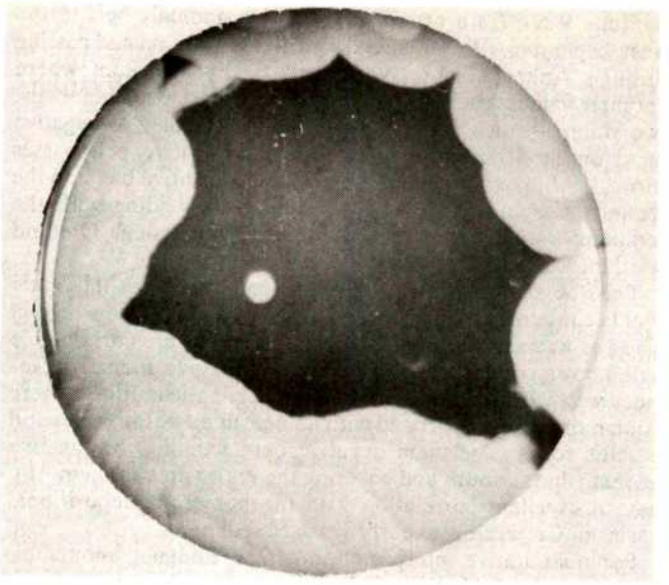

Fig. 1 Wave propagation in the uncatalysed gallic acid–bromate system. The diameter of the Petri dish is 100 mm. Concentrations (molar): H_2SO_4, 1.09; $NaBrO_3$, 0.136; gallic acid, ~0.04 (saturated solution). The reaction time of the mixture was 12 min 20 s. To avoid reflections, the dish was uncovered while the photograph was taken.

observed for periods of about 30 min, the waves fading slowly.

In several cases spatial irregularities were observed at the beginning of the reaction: areas not yet reached by a wave front suddenly showed an irregular colour change propagating about 10 times faster than wavefronts. This effect disappeared as soon as a wavefront reached these areas. The same effect was reported by Zaikin and Zhabotinskii[3]. We assume this effect to be a pseudo-wave which propagates much faster than ordinary trigger waves, and which appears only where trigger waves have not yet started propagating[9].

There has been some controversy as to whether those leading centres (also called pacemakers) from which the waves propagate may appear spontaneously. It arose because Winfree[10] assumed that in the BZR leading centres were caused by dust particles or similar heterogeneities of the system. Note that the general theory of irreversible thermodynamics forces an amplification of fluctuations in the system. An oscillatory reaction involves autocatalytic steps which are able to amplify such fluctuations.

Zaikin and Kawczynski[11] developed a theory to explain this effect. They distinguished between the pacemaker and the leading centre. The pacemaker is caused by a permanent local heterogeneity (such as a dust particle), whereas the leading centre can only be produced by an initial pertubation of concentration or phase. It would be very difficult to exclude completely all impurities, such as dust particles, and impurities may constitute a much greater potential disturbance of the homogeneity of the system than the fluctuations under study. Thus a macroscopic heterogeneity might be expected to trigger waves more effectively than can fluctuations. Similar earlier controversies concerned the oscillatory behaviour of the Bray–Liebhafsky reaction which was thought to be caused by gas bubbles.

We have given an additional example showing that a well defined macroscopic concentration gradient can also trigger chemical waves. It should be emphasised, however, that even when all impurities were excluded as far as possible wave propagation started spontaneously. Presumably the induction and synchronisation of the temporal and spatial phase difference in the propagating wave took a longer time in this case. The pseudo wave seems to be an early step in the development of this process.

The brown colour observed is probably caused by oxidative formation of a semiquinone compound from gallic acid, but the precise reactions that make up this oscillatory reaction system are not yet known.

Gravity field of Benue Trough, Nigeria

Chris Adighije

Geology Department, University of Ibadan, Ibadan, Nigeria

The Benue Trough, located at the Gulf of Guinea re-entrant on the West African coast (Fig. 1), is a unique Cretaceous rift whose origin is related to the opening of the South Atlantic and the continental separation of Africa from South America. The trough extends northeastwards for ~700 km from the Niger Delta to the Chad Basin and is filled with an estimated 5,000 m of Cretaceous sediments and volcanic rocks. Studies on the origin and tectonic evolution of the Benue Trough have been based so far principally on surface geological and geochemical evidence[1–5]. Gravity measurements by Cratchley and Jones[6] in the middle Benue area are of limited significance because they were aimed mainly at resolving the then controversy between the tensional and compressional[8] hypotheses. New and more extensive gravity data presented here indicate rifting in the upper and middle sections of the trough whereas the complex field over the lower section could be due to an 'unsuccessful' attempt to open into an ocean during the late Cretaceous.

Six hundred additional gravity measurements were made at 2–10 km spacings along passable roads (in the lower and upper areas of the trough) to fill up earlier gaps in information[9]. A Canadian Scintrex CG-2 gravimeter No. 305G, with a repeat accuracy of 0.01 mGal and average drift of 0.06 mGal h^{-1}, was used in measuring the gravity values. About 20% of the gravity stations were located on known elevation bench marks; elevations of other stations were determined by using a single Paulin system altimeter in loops of up to 2-h duration. These elevations have an estimated error of ±15 m. Station positions which have been established on a 1:1,000,000 scale map are correct to ±500 m. Free-air, Bouguer, terrain and latitude corrections were applied to the observed gravity values. The maximum possible error of the final Bouguer anomaly values is estimated to be about ±3 mGal.

Figure 2 is the resulting Bouguer contour map with relative gravity values ranging from −60 mGal near Kaltungo to +20 mGal near Abakaliki. Generally the Bouguer values decrease towards the flanking basement complex areas; for example, the value near Jos (Younger Granite province) is −90 mGal (ref. 9). Two distinct regions can be easily identified: (1) a positive gravity anomaly belt whose axis begins from south of Ishiagu, reaches +20 mGal near Abakaliki and terminates near Gboko. Beyond Gboko, the positive anomaly becomes much smaller in magnitude and disappears near south of Zurak

0028–0836/79/450199—03$01.00

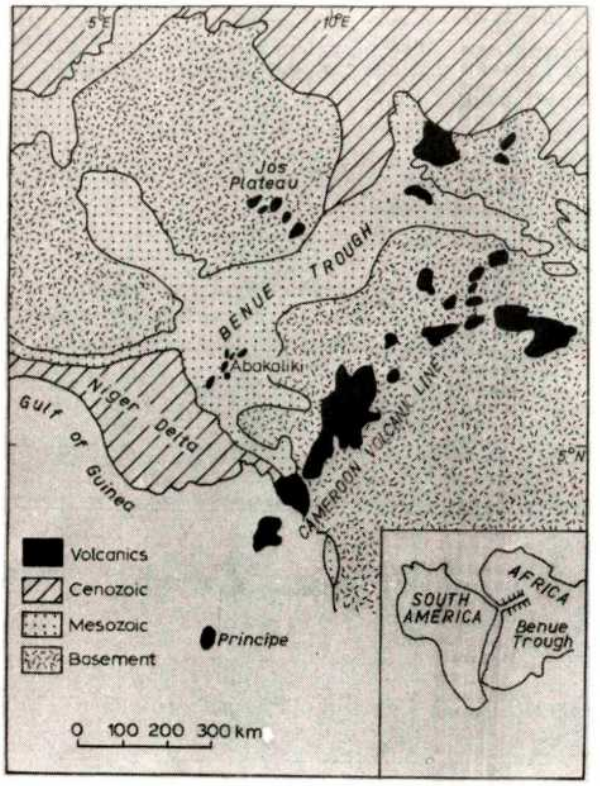

Fig. 1 Location map of Benue Trough.

(latitude 9°N); (2) a prominent negative anomaly belt to the west, beginning with −40 mGal south-east of Benin and passing through Ankpa, Wase, Wikki and finally Potiskum where anomaly values reach −60 mGal. Besides these two main belts, two others—much less defined—are discernible. A negative band on the eastern flank of the main positive belt passes through Afikpo, Ogoja and Wukari, and a positive band on the western margin of the map and almost coinciding with the sediment–basement boundary can be traced through Ore and south of Lokoja to Shendam.

The Bouguer map is relatively more complex south of latitude 9°N because of the complex geological structure of this region. The positive and negative Bouguer anomalies are correlatable with known surface geology; the belt of positive anomaly coincides well with the core of the Abakaliki anticlinorium where Albian shales are associated with numerous mafic intrusives and basaltic rocks. The main negative belt, flanking the positive anomaly in the south and covering the entire area in the north, has an excellent correlation with the numerous depositional basins of Cretaceous to early Tertiary sediments.

For quantitative interpretation of the Bouguer anomalies, four profiles (AA′, BB′, CC′, DD′) across the trough were selected (Fig. 2). The most outstanding feature of the profiles is a regional positive anomaly over the whole trough floor (Fig. 3). The profiles of the regional anomaly display striking similarity with one another, suggesting a deep-seated structure of considerable extent along the trough. Each profile in Fig. 3 also shows the uplift in the Moho boundary that would cause the gravity regional (with a mantle–crust density contrast of 0.57 g cm^{-3}). The mantle–crust interface (Moho) thus seems to have been elevated by ~1.5 km in the Lower Benue

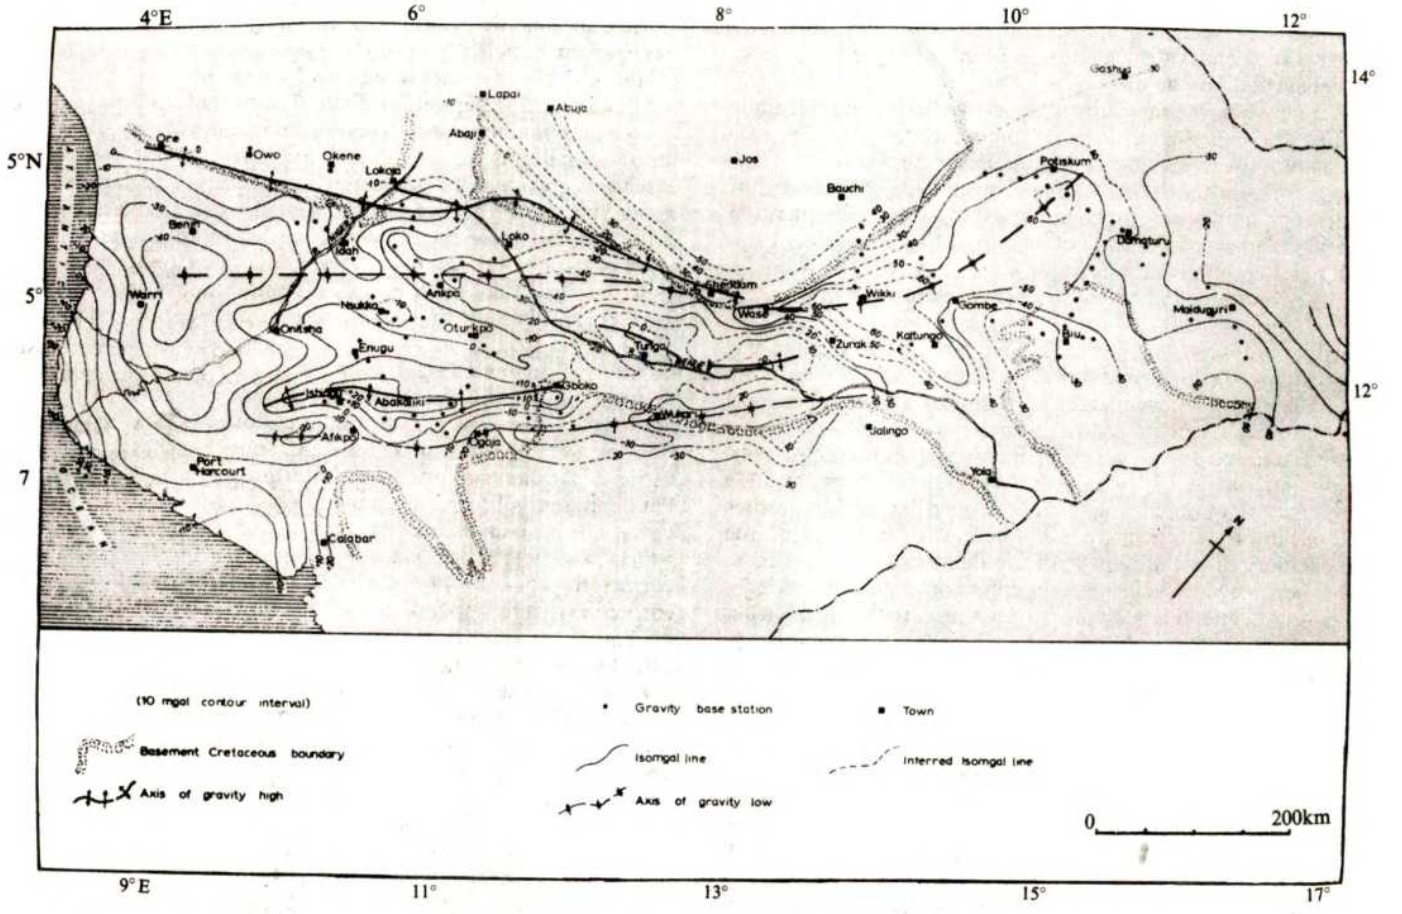

Fig. 2 Bouguer anomaly map of Benue Trough.

and ~3.0 km in the Upper. On the other hand, the width of the Moho uplift decreases from 170 km in the Lower to 70 km in the Upper Benue.

The residual positive anomaly belt from Abakaliki to Gboko has been interpreted as a two dimensional body of density 2.90 g cm^{-3}, average width of 30 km, and extending from a depth of 10 km down to the Moho (Fig. 4).

Uplifting of the Moho beneath rift structures has also been observed in other regions—Kenya Rift Valley[10], Gulf of Suez[11], Red Sea[12], Baikal Rift[13] and Oslo Graben[14]. Artsybash and Kogbe[15] had previously obtained a rather high value, 10–12 km, for the mantle uplift in Middle Benue. This is primarily due to their use of too small a value for the mantle–crust density contrast, namely, 0.17 g cm^{-3}, as against the 0.57 g cm^{-3} used here. The relatively small mantle uplift, as obtained in this study, could relate to the fact that the Benue Rift became inactive during the late Cretaceous following the rotation of the African plate and the consequent shift of tectonic activity to the Cameroun volcanic line[5].

The shape and size of the high density material that generates the main positive anomaly belt (Abakaliki–Gboko) is shown in Fig. 4. This anomalous body can hardly be considered as an intrusive because of its very large dimensions. It rather resembles a 'mantle diapir' which, in turn, might have been the source of the volcanic rocks in the area.

The negative anomalies which flank the positive belt in the south, and form the axial plane in the north, are considered to be due entirely to the sediments that fill the Benue Trough. The

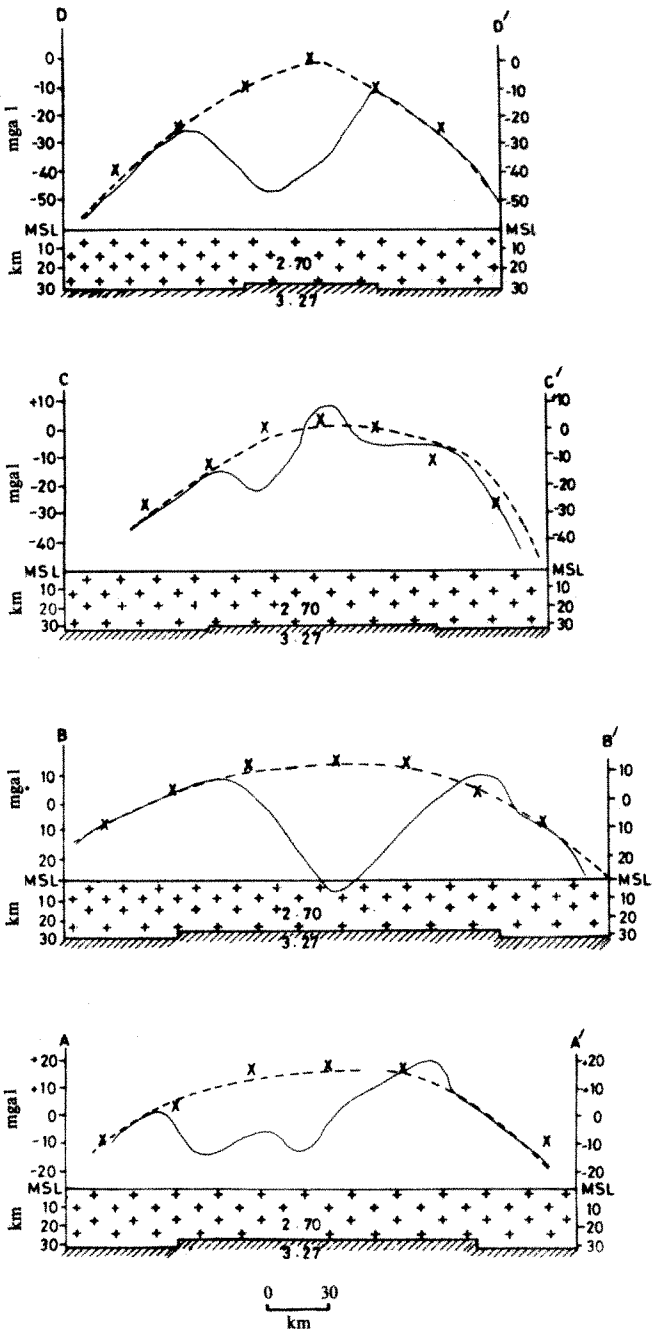

Fig. 3 Calculated regional anomaly for crustal models along profiles AA′–DD′. Solid line, observed gravity; dashed line, regional anomaly; ×, calculated anomaly due to the regional model.

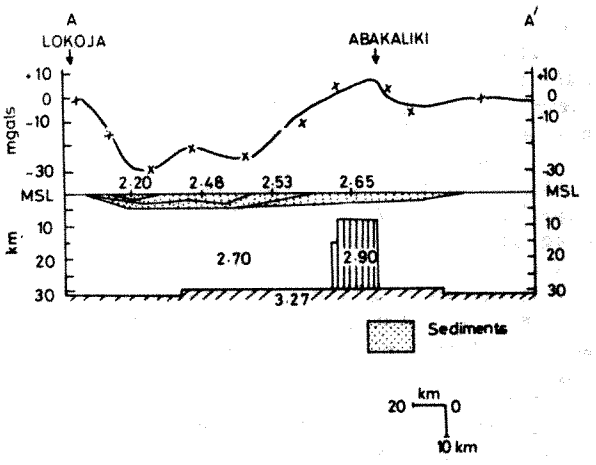

Fig. 4 Calculated residual gravity anomaly for model along profile AA′. Solid line, residual anomaly; ×, calculated anomaly.

maximum thickness of sediments in the Lower Benue area was calculated as 4,250 m (Fig. 4). In the Upper sections a maximum thickness of 6,000 m has been obtained[6].

The results of this study are consistent with a tensional origin related to the opening of the South Atlantic. The gravity anomaly patterns in the upper and middle sections of the trough are similar to those of other sediment-filled rifts. The complexity of the gravity field in the Lower Benue can be attributed to its proximity to the hotspot and triple junction which was beneath the present Niger delta. This was associated with an unsuccessful attempt to open the Benue Trough into an ocean during the late Cretaceous.

I thank H. Higasinaka for support and M. A. Olade and A. Roy for useful discussions. Computer models were calculated at University of Birmingham, UK. Fieldwork was financed by grants from the University of Ibadan.

Evidence for organically associated iron in nearshore pore fluids

Wm. Berry Lyons, Henri E. Gaudette & Peter B. Armstrong

Department of Earth Sciences
and Ocean Processes and Analysis Laboratory,
University of New Hampshire, Durham, New Hampshire 03824

The role of dissolved organic matter (DOM) in the speciation of trace metals in natural waters is poorly understood[1-3]. Although dissolved organic matter–iron associations have been observed in freshwater systems[4-6], it has been thought that DOM–iron species are not significant in saline waters[7]. Yet recent studies have suggested that iron–DOM interactions in the pore waters of anoxic marine sediments may be important[8,9]. The possibility of organically associated trace metals in anoxic water has been used to explain why metal concentrations are higher than those predicted by sulphide-mineral equilibria[10,11]. We present here data that indicate that strong iron–DOM associations do occur in the anoxic pore waters of nearshore marine sediments and that both the total dissolved iron and organically associated iron change seasonally.

Five box cores were taken within 1 m^2 of each other between February and September 1978, in a subtidal area in the Great Bay estuary, New Hampshire. The cores were treated very carefully so that the sediment and its pore fluid would not be exposed to the atmosphere at any time. In the laboratory the corer was placed in a nitrogen-filled glove bag, extruded, sectioned into 2-cm sections, centrifuged and filtered through precleaned 0.4-μm membrane filters. Details on handling and cleaning procedures are published elsewhere[12,13]. The inert atmosphere was maintained to minimise oxidation artefacts[14-16]. While in the glove bag, the filtered pore water samples were separated into two aliquots and one acidified to pH ~1 with ultrapure HNO_3 and the other acidified to a pH of ~2.8 with ultrapure HCl. The HNO_3 acidified samples were then placed into a water bath at 90 °C, heated for 1 h and analysed for total dissolved iron using the technique of Murray and Gill[17]. The HCl acidified samples were passed through a column of the macroeticular resin, Amberlite XAD-2, utilising the flow parameters outlined by Mantoura and Riley[18]. This resin has been shown to be very efficient in removing humic substances from natural water samples of pHs between 2 and 3 (refs 19–21). Due to the harshness of this procedure (acidification), the Amberlite extractable iron fraction should be considered as iron that is very strongly associated with the humic material present in the pore fluids. Sugimura *et al.*[22] have shown, however, that 80–90% of the total iron present in seawater is removed by procedures similar to those outlined above. Only 10% of the total iron is removed by the resin if the sample is not previously acidified. This technique probably underestimates the iron that is actually associated by pore water DOM. The resin was eluted with ultrapure 1M NaOH, acidified to pH ~1 with ultrapure HNO_3, heated in the water bath for 1 h and analysed for 'humic-substance associated iron' or organic iron. The standard deviation of the iron measurements reported as a coefficient of variation was 2% at 10 μmol^{-1} and 10% at 2 μmol^{-1}. The data are shown in Table 1.

The total dissolved iron values proceed through a seasonal cycle with the highest concentrations observed in the late spring and the lowest in mid-summer. This seasonal cycle of dissolved Fe can be correlated with bacterial cycling of sulphur and DOM in these sediments[23]. In the spring, as the temperature of the water and the sediment increases, anaerobic fermenting bacteria begin to metabolise at a faster rate producing reduced end-products which lower the sediment Eh. As the Eh is lowered more Fe^{3+} is solubilised to Fe^{2+} in the pore waters. Bacterially mediated sulphate reduction occurs as the temperature increases and the Fe present in the pore fluids in the late spring is removed by mid-summer by the *in situ* formation of FeS. Similar seasonal pore cycling of Fe has recently been observed in temperate salt marsh sediments[24].

The May samples also have the highest percentages of organic iron in the pore waters, with an average of 31% of the total iron being organically associated. This compares with 10% or less for the other sampling dates. It thus seems that the production and removal of this organic-iron fraction is strongly related to sedimentary microbial dynamics. Laboratory experiments have shown that the pigment and lipoidal fractions (1,500–50,000 molecular weight fraction) of DOM from the bacterial degradation of algae can form water soluble iron-organic associations[25]. It has been suggested that a syntrophic relationship exists between fermenting and sulphate reducing bacteria and that fermenting bacteria produce organic substrate for subsequent sulphate reducing bacterial growth[26]. Although our conclusions are based on a single set of samples from one site, it seems that this interaction between bacterial groups may also have a profound effect on trace metal speciation in anoxic waters.

We thank Bill Orem for his help in obtaining the samples, Mark Hines for reviewing the original manuscript and Jon Kim for help in reviewing the literature. This work was supported by NSF grant OCE77-20484 and Sea Grant 04-8-MOI-79.

Cell-surface labelling reveals no evidence for membrane assembly and disassembly during fibroblast locomotion

C. A. Middleton

Department of Anatomy, School of Medicine,
The University of Leeds, Leeds, UK

As a cultured fibroblast moves, particles or pieces of debris attached to its surface move backwards with respect to both the cell and the substrate[1,2], as also do concanavalin A (Con A) receptors in the membrane of the leading lamella[3]. One suggested explanation is that membrane components from the cytoplasm are assembled and introduced into the surface membrane of the moving cell close to its leading edge and flow backwards to a 'sink'; there the membrane is disassembled, and its components enter the cytoplasm and flow forward within the cell, to be re-introduced later into the surface membrane[1,4]. However, because cell-surface receptors can be redistributed as a result of cross-linking by external ligands[5,6] it has been proposed that the backward flow of Con A receptors and particles may result from such a cross-linking rather than from a flow of intact cell membrane[7,8]. To investigate these alternatives, I have studied moving fibroblasts by means of a cell membrane label that does not induce the redistribution of its receptors. My results do not seem compatible with the membrane flow model.

The Thy-1.1 alloantigen (formerly ΘAKR) is an integral membrane glycoprotein originally identified on mouse T lymphocytes[9] and also found on fibroblasts from Wistar–Furth (W/Fu) rats[10,11]. Treatment of lymphocytes[12] and W/Fu fibroblasts (C.A.M., unpublished observations) with alloantiserum directed against this alloantigen (anti-Thy-1.1) does not result in the redistribution of the antigen. This does not imply, however, that the antigen is anchored in the membrane, for in lymphocytes[12], and both suspended and spread W/Fu fibroblasts (C.A.M., unpublished observations), incubation with an additional layer of antibody directed against anti-Thy-1.1 will induce the redistribution of the antigen into patches and caps.

Cultured rat W/Fu fibroblasts were cooled rapidly to inhibit locomotion and incubated with mouse anti-Thy-1.1 in the cold. The cells were then returned to 37 °C and the locomotion of a selected cell was filmed: ruffling and locomotory activity of the cells was unaffected by incubation with anti-Thy-1.1. The cells were again cooled to prevent further locomotion, and before fixation were incubated with fluorescein-conjugated rabbit anti-mouse IgG (anti-MIg-Fl) to make possible visualisation of the anti-Thy-1.1 (details in Fig. 1). The selected cell was then observed by incident light fluorescence microscopy.

When there was no incubation at 37 °C, so that cells were unable to move between treatments with the two antisera, there was an even distribution of fluorescent label (Fig. 1), indicating

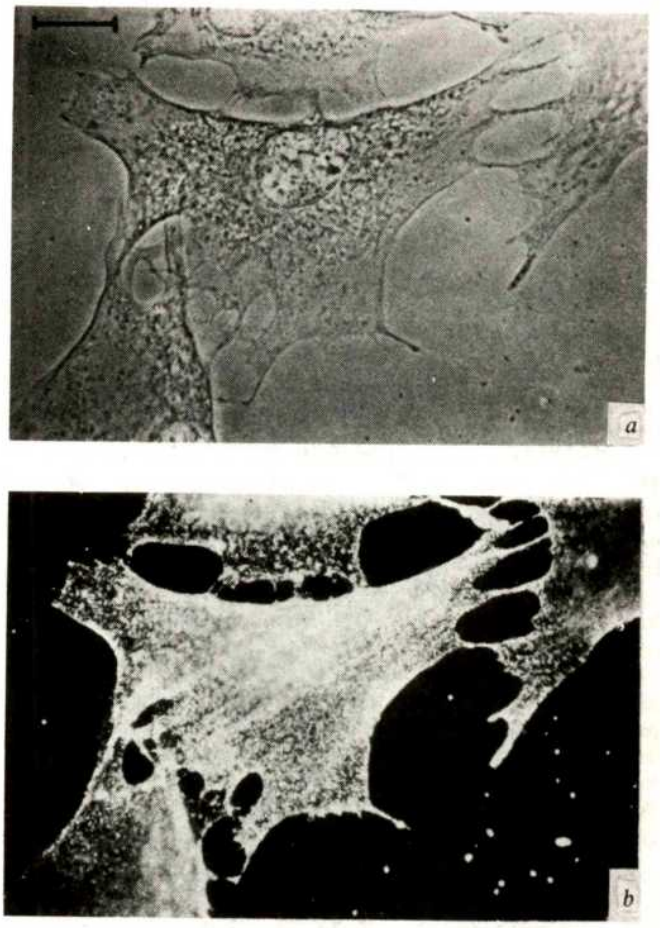

Fig. 1 Fluorescent labelling of Thy-1.1. Fibroblasts were initially obtained as contaminants of myoblast cultures from neonatal W/Fu rats. They were subsequently maintained by twice weekly subculture in Dulbecco's modified Eagle's medium (MEM) containing 10% fetal calf serum (FCS, Flow Labs), penicillin (100 IU ml^{-1}) and streptomycin (100 $\mu g\ ml^{-1}$). When required, cells were collected and adjusted to a concentration of $5\times10^3\ ml^{-1}$ in medium as above, and 1-ml aliquots of this suspension were plated out on to 13-mm diameter glass coverslips contained within Linbro multidish wells (16 mm diameter, Flow Labs). The coverslips had previously been marked, using Indian ink, with a reference grid of side approximately 2 mm to allow the subsequent localisation and identification of selected cells. After 24 or 48 h culture, a selected coverslip was cooled rapidly by washing in HEPES-buffered MEM (MEM-H) containing 20% FCS at 4 °C and then incubated in anti-Thy-1.1 (1:4) prepared as described by Raff[18] for 30 min at 4 °C. The coverslip was then thoroughly washed in MEM-H at 4 °C and maintained in MEM-H plus 10% FCS at 4 °C, and a suitable cell selected. The cold medium was then replaced with MEM-H plus 10% FCS prewarmed to 37 °C and the selected cell was filmed under phase contrast optics by time-lapse cinematography (1 frame per 3 s) for 15–180 min. At the end of the period of filming, the culture was rapidly cooled by washing in MEM-H plus 20% FCS at 4 °C and then incubated in anti-MIg-Fl (1:10, Miles Labs) for 30 min at 4 °C. After thorough washing in MEM-H at 4 °C, the culture was fixed in absolute methanol for 2 min and mounted in phosphate-buffered saline. The culture was examined using a Leitz Orthoplan microscope equipped with phase contrast and incident light fluorescence optics suitable for fluorescein fluorescence. The filmed cell was re-identified using the reference grid and paired phase contrast and fluorescence micrographs obtained. *a*, *b*, Distribution of fluorescence on control cells. The period of locomotion at 37 °C was eliminated from the above protocol by maintaining the cells at 4 °C throughout; incubation with anti-Thy-1.1 was followed immediately by washing and incubation with anti-MIg-Fl. A group of cells was photographed with phase contrast optics (*a*) and with incident light fluorescence optics (*b*). Scale bar, 20 μm.

an even distribution of Thy-1.1 over the surface of the cell. Fluorescent labelling was prevented if there was no incubation with anti-Thy-1.1.

Figure 2 shows an experiment in which a selected cell was filmed for 30 min at 37 °C after incubation with anti-Thy-1.1. The cell ruffled during filming and stills taken from the first (Fig. 2*a*) and last (Fig. 2*b*) frames of the film show that regions of the leading lamella advanced up to 30 μm (Fig. 2*c*). Treatment with anti-MIg-Fl showed that the distribution and intensity of the

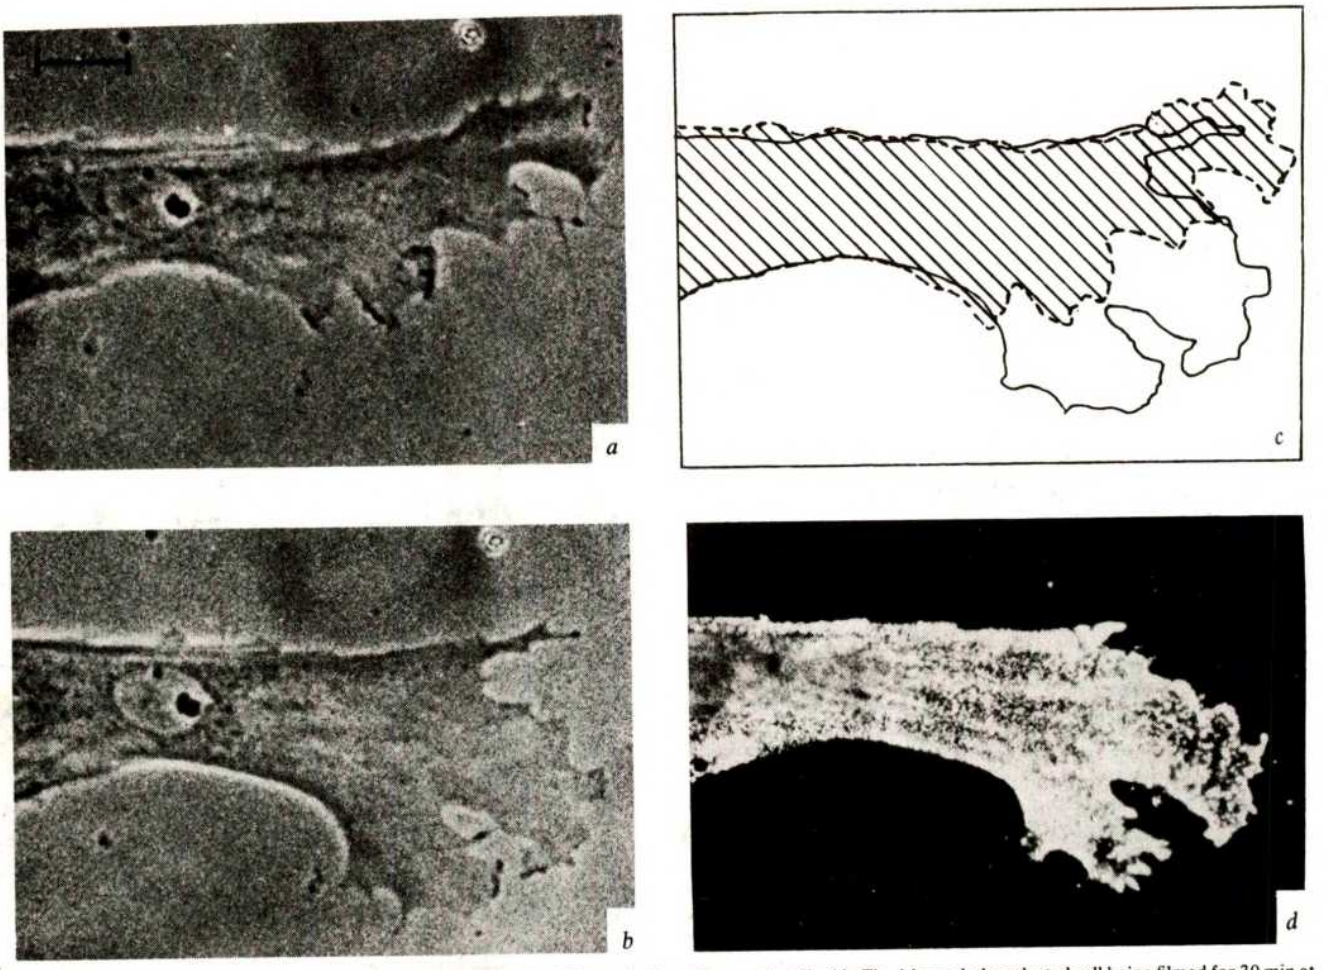

Fig. 2 Distribution of fluorescence on a fibroblast after locomotion. The method used was as described in Fig. 1 legend, the selected cell being filmed for 30 min at 37 °C after incubation with anti-Thy-1.1 and before incubation with anti-MIg-Fl. *a*, *b*, Stills taken from the time-lapse film at the start of filming (*a*) and at the end of filming (*b*); *c*, superimposition of tracings from *a* and *b* to show the movement of the cell; *d*, fluorescence micrograph of the same cell. Scale bar, 20 μm.

fluorescent labelling (Fig. 2*d*) were indistinguishable from that on control cells which had not moved (compare Figs 1*b* and 2*d*). Similar experiments in which the cells moved for 15–180 min after incubation with anti-Thy-1.1 antiserum yielded identical results.

Con A labelling experiments had suggested a coordinated backward flow of newly assembled membrane from the leading edge of the cell[3], but my results are incompatible with that. If membrane were assembled during the period of locomotion, the newly assembled membrane would contain Thy-1.1 previously within the cytoplasm, unavailable to the anti-Thy-1.1 and therefore not detectable by anti-MIg-Fl. A coordinated backward flow of newly assembled membrane would therefore appear as a gradual retreat of fluorescent label from the leading edge, because, with increasing time, more and more membrane containing Thy-1.1 unavailable for subsequent labelling would be introduced at the leading edge of the cell. There was no sign of such a retreat.

Although my results argue against coordinated backward flow of the membrane, some less organised flow may be possible because membrane components, both protein and lipid, are free to diffuse in the plane of the membrane (see ref. 6 for review), and so components inserted during locomotion might be expected to mix with those already present on the cell surface. In my experiments any Thy-1.1 inserted during locomotion is unavailable for subsequent labelling (see above). This will mix with and dilute the Thy-1.1 already present on the surface and available for labelling at a rate largely determined by the speed of membrane assembly and disassembly. This dilution would be detected as a gradual decrease, with time, in the intensity of subsequent labelling. Studies of particle movements during fibroblast locomotion suggested that the membrane was being assembled and disassembled at a rate equivalent to replacing the entire surface of the cell approximately once every 10 min (ref. 2). In my experiments, such a rate should have led to a rapid decrease in the intensity of labelling with increasing periods of locomotion. I have not estimated fluorescence quantitatively, but qualitatively no such decrease was observed. Cells that had been allowed to move for periods of up to 180 min were apparently as fluorescent as control cells that had not moved and it was still possible to label fluorescently cells that had been maintained at 37 °C for 24 h after incubation with anti-Thy-1.1.

In considering the dilution of the cell-surface label in this way I make two assumptions. First, if the membrane is disassembled, Thy-1.1/anti-Thy-1.1 complexes will be degraded and cannot be reintroduced into the membrane for subsequent re-labelling. Second, at the proposed membrane sink, anti-Thy-1.1 is not released from the Thy-1.1 antigen and is therefore not available to diffuse through the medium to bind to uncomplexed Thy-1.1 antigen.

Both assumptions seem justified, as membrane-bound antibodies are usually endocytosed, enter the lysosomal system and are degraded[13,14]. Membrane-bound cationised ferritin has been reported to enter secretion granules and Golgi cisternae[15], but even there it had often lost its association with the membrane[15]. Even if the second assumption was incorrect and anti-Thy-1.1 was released at the sink, its recomplexing with unoccupied Thy-1.1 would have to be unexpectedly efficient to have maintained the observed levels of fluorescence, in view of the predicted rates of membrane assembly and disassembly and its likely rate of diffusion in the culture medium.

It seems unlikely from the results presented here that cell locomotion involves the assembly and disassembly of membrane components at the rate predicted by the membrane flow model.

Probably the backward movement of Con A receptors, and possibly also that of particles, during locomotion, results from a ligand-induced redistribution of membrane components. However, it is difficult to account for the commonly observed [16] backward movement of blebs and ruffles in this way. The movement of these membranous organelles suggests that some backwardly directed force is generated on the surface of moving cells, but it seems unlikely to be due to the flow of intact membrane. Conceivably, the proposed flow of the membrane lipids alone[17] could generate such a force, but this flow remains to be demonstrated.

I thank Dr P. Lake for the anti-Thy-1.1 antiserum and Dr Joan Heaysman and Professor Martin Raff for helpful comments and advice.

Genetic polymorphism of human complement C4 and detection of heterozygotes

Z. L. Awdeh, D. Raum & C. A. Alper

Center for Blood Research, Boston, Massachusetts 02115

Many components of complement exhibit inherited structural polymorphism, with at least two alleles being common in one or more of the major races of man[1–9]. However, definition of genetic polymorphism in human C4 has proved a difficult task. Differences between the electrophoretic patterns of C4 in EDTA plasma from different individuals were detected by Rosenfeld and coworkers[10,11], but these differences could not be explained by any simple genetic model. O'Neill and coworkers[12], using a system similar to that of a previous study[13], interpreted the electrophoretic patterns in a completely different way from previous workers[13,14], stating that there were three: F, FS and S. They also found that C4 F carried Rodgers or Rg(a+) serologic reactivity and C4 S carried Chido or Ch(a+) reactivity[15]. These 'blood group' antigens had previously been shown to be closely linked to HLA[16,17]. O'Neill proposed[15] that C4 is genetically controlled by two closely linked loci, one for C4 F and one for C4 S, and postulated that deficiency states for one or the other locus are common but rarely occur together. The sets of haplotypes were postulated to be *C4 Fs*^{0} (or *C4 F*), *C4 f*^{0}*S* (or *C4 S*) and *C4 FS*. In this model, the C4 F individuals are Rg(a+)Ch(a−), C4 S individuals are Rg(a−)Ch(a+) and C4 FS persons are Rg(a+)Ch(a+). The chief problem with the methods of typing, both electrophoretic and serologic, is that *C4 Fs*^{0} and *C4 f*^{0}*S* can usually only be detected in the homozygous state, thus severely limiting their usefulness. We have now developed a method of C4 typing that allows detection of *C4 Fs*^{0} and *C4 f*^{0}*S* in heterozygotes, and permits the study of genetic polymorphism of *C4* in the general population. Our observations confirm and extend the two-locus genetic model of O'Neill and coworkers.

Five kinds of patterns were found using samples from randomly selected caucasians, as shown in Fig. 1: (1) F = S, (2) S only, (3) F only, (4) F > S, (5) F < S. When the stained crossed immunoelectrophoresis patterns were subjected to quantification of the ratio between the F and S peaks by placing the patterns over 1-mm graph paper and counting squares, for F > S, F/S was 219 ± 25% (±1 s.d.) for $n = 10$ and for F < S, F/S was 52 ± 7% for $n = 10$. For F = S, the ratio was 96 ± 8%, with $n = 13$. Thus, patterns (2) and (3) are, as described by O'Neill and coworkers[15], from individuals who are *C4 f*^{0}*S/f*^{0}*S* and *C4 Fs*^{0}*/Fs*^{0}, respectively, and patterns (4) and (5) are from individuals predicted by them to occur but not distinguishable by their typing system, *C4 Fs*^{0}*/FS* and *C4 f*^{0}*S/FS*. Pattern (1) is the only ambiguous phenotype, as it would be given by both *C4 FS/FS* and *C4 f*^{0}*S/Fs*^{0} individuals.

The concentrations[18,19] of C4 in the plasma (as per cent normal) of various C4 types are: for 32 *FS/FS* individuals, 109 ± 44% (±1 s.d.); for 24 *Fs*^{0}*/FS* individuals, 101 ± 48%; for 9 *Fs*^{0}*/Fs*^{0} individuals, 75 ± 24%; for 18 *FS/f*^{0}*S* individuals, 100 ± 56%; for 4 *f*^{0}*S/f*^{0}*S* individuals, 70 ± 24%; and for 7 *Fs*^{0}*/f*^{0}*S* individuals, 67 ± 24%. It is of interest that the means of C4 serum concentration in individuals of different C4 types differed, as expected. However, there was considerable overlap,

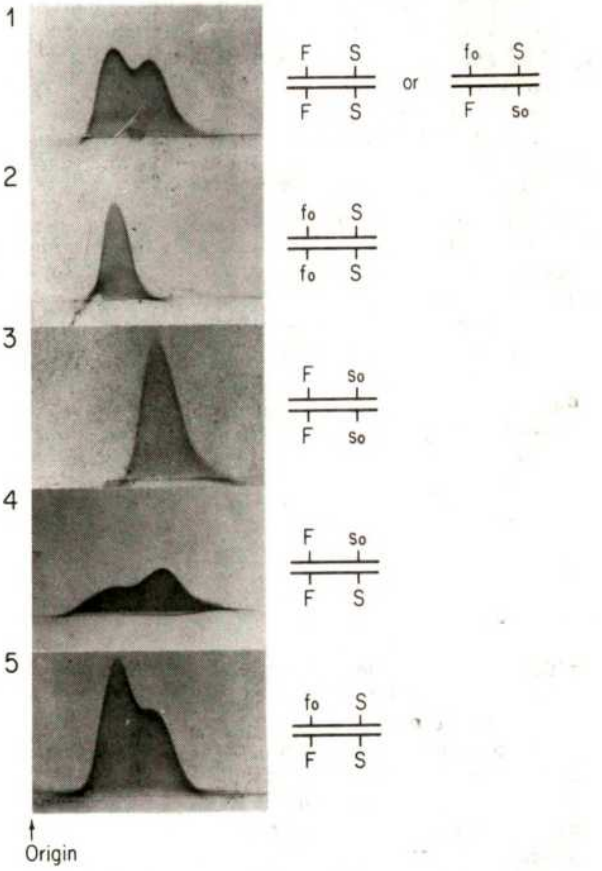

Fig. 1 Crossed immunoelectrophoresis patterns for the five detected phenotypes of C4. Fresh plasma from whole blood collected into Na_2 EDTA at 1.1 mg ml^{-1} was used immediately or stored at −80 °C and thawed just before analysis. The plasma samples were incubated with neuraminidase (Sigma) from *Clostridium perfringens* at 5 U ml^{-1} for 15 h at room temperature while dialysed against 0.1 M phosphate buffer, *p*H 7.0, containing 0.005 M Na_2EDTA. Desialated plasma samples were then subjected to electrophoresis in 0.8% agarose (Marine Colloids) using 0.075 M Veronal buffer containing 0.005 M EDTA at *p*H 8.6 for both gel and vessels. Electrophoresis was carried out at 300 V and 50 mA for 3 h by which time a HbA marker had migrated 6.0 cm. Gel strips (3 mm wide) containing separated proteins and extending from the origin to the HbA area were transferred to a second agarose gel containing goat anti-human C4 (Atlantic Antibodies) at 1% and then subjected to crossed immunoelectrophoresis[25]. In a few instances, immunofixation[26] with anti-C4 was used after the first separation.

so that serum C4 concentrations were of little use in distinguishing C4 types, including *C4 FS/FS* from *C4 f⁰S/Fs⁰*, or even *C4 Fs⁰/Fs⁰* and *C4 f⁰S/f⁰S* from *C4 FS/FS*.

When the frequencies of haplotypes *FS*, *f⁰S* and *Fs⁰* were calculated in a population of 203 randomly selected caucasians assuming all F = S patterns to be of genotype *FS/FS*, the frequencies of *FS*, *Fs⁰* and *f⁰S* were, respectively, 0.74, 0.14 and 0.12. These frequencies were not significantly different from those predicted by the Hardy–Weinberg equilibrium ($P = 0.54$). The frequency of *FS* is overestimated (by about 3%) and the frequencies of *f⁰S* and *Fs⁰* are underestimated. Evidence for the autosomal codominant inheritance of these *C4* genes was obtained in family studies, as shown in Table 1 in which only expected types were found in offspring of various mating pairs, and the offspring types and ratios were close to those predicted. Inheritance of *C4* haplotypes for three families is illustrated in Fig. 2.

Although the genetic model for *C4* polymorphism in man as suggested by O'Neill and coworkers[15] explains some of the previously confusing and conflicting observations, the problem of detecting the various proposed *C4* 'haplotypes' in their heterozygous combinations remained. In our experiments, overlap between C4 F and C4 S occurred in all existing separation systems, including isoelectric focusing in polyacrylamide gel. O'Neill and Dupont[20] attempted to identify *C4 FS/f⁰ S* and *C4 FS/Fs⁰* patterns based on the intensity of immunofixation bands in their system. By comparison with frequencies predicted by the Hardy–Weinberg equilibrium and their observed homozygote frequencies, they were able to detect less than 20% of predicted heterozygotes. For these reasons we used neuraminidase treatment to reduce heterogeneity of each of the two *C4* locus products. This resulted in the ability to separate and quantify C4 F and C4 S by ordinary agarose gel electrophoresis, thereby permitting *C4* genotypes to be determined in random individuals and families. Thus, it has become feasible to demonstrate the inheritance of *C4* polymorphism by classic mendelian genetics.

The only remaining ambiguity in determining *C4* haplotypes is the distinction between *C4 FS/FS* and *C4 f⁰S/Fs⁰* ($F = S$), much like AA and AO blood group genotypes manifested by the single phenotype, group A. This ambiguity could usually be resolved by family studies (see family I, Fig. 2). Homozygous C4 deficiency[21,22] has been found in only six individuals and is thus extremely rare. There may also be ambiguity in the instance where the rare, presumed haplotype for this deficiency, *C4 f⁰s⁰*, occurs in an individual with a single expressed structural haplotype. This problem, of course, is found in any genetically polymorphic system where a silent gene or haplotype is present. In this case, it is possible that 'anomalous' inheritance of structural types occurs.

In the mouse, a duplication of the *C4* locus, *Ss* and *Slp*, within the *H-2* region, also seems to occur, although one of these proteins, Slp, is not functional[23]. In the guinea pig, only one genetic locus has been detected for C4 (ref. 24). In man, C4 patterns are due to the products of two loci in which the two genes are probably so closely linked that crossing over between them is an unusual event. This and the ability to detect heterozygotes of all possible haplotypes will eventually allow proper segregation and linkage analysis for *C4* especially with regard to the genetic loci for the complement proteins, C2 and Bf, and the HLA complex.

Genetic defect in secretion of complement C5 in mice

Yuet M. Ooi & Harvey R. Colten

Division of Cell Biology (Cystic Fibrosis), Department of Medicine, Children's Hospital Medical Center, and Department of Pediatrics, Harvard Medical School, Boston, Massachusetts 02115

A genetic deficiency of the fifth (C5) component of complement[1–3], a serum glycoprotein of molecular weight (MW) 220,000 (ref. 4), has been found in 39% of inbred strains of mice[3]. Sera of deficient mice lack detectable C5 activity and protein[2,3]. In addition deficient mice produce antibody to mouse C5 when injected with sera from C5 sufficient (normal) strains. Levy *et al.*[5] showed that somatic cell hybrids between C5 deficient (B10.D2/old line) macrophages and either C5 sufficient (B10.D2/new line) mouse kidney or chicken erythroblasts secreted haemolytically active mouse C5 *in vitro*. Several possible molecular mechanisms to account for the findings were considered, but insufficient direct data were available to choose among them. We recently reported that mouse (CD.1 strain) peritoneal cells in culture synthesise and secrete a single chain precursor, pro-C5 (MW ~ 210,000), of the two-chain (α chain, 125,000 and β chain 83,000 MW) C5 protein[6]. Radiolabelled precursor C5 was contained within the cells and was secreted into the tissue culture media. Using similar methods, we now find that C5 deficiency in each of five different mouse strains (AKR, SWR, DBA/2J, A/HeJ and B10.D2/old line) is due to a failure in secretion of C5 protein and not to a failure in biosynthesis of pro-C5.

Resident peritoneal macrophage cultures from five mouse strains genetically C5 deficient and from two normal (Swiss and B10.D2/new line) strains were established and pulsed with medium containing ^{35}S-labelled methionine. After 24 h, newly synthesised intracellular (cell lysate) and extracellular protein were quantitated by trichloroacetic acid (TCA) precipitation, specific C5 antigen by immunoprecipitation and C5 function in the extracellular medium by haemolytic assay. The size and subunit composition of the radiolabelled C5 protein were determined on SDS-polyacrylamide gel electrophoresis in reducing conditions.

Total protein (TCA-precipitable radioactivity) was similar in C5-deficient and normal cells in both the intracellular and extracellular compartments (Table 1). ^{35}S-methionine was incorporated into C5 antigen contained intracellularly and was secreted by normal peritoneal cell cultures. Although peritoneal cells from the deficient strains synthesised an amount of immunochemically detectable C5 protein similar to that produced by the normal strains, all of the C5 antigen was contained in the cell lysates (Table 1). In addition, approximately 2.5×10^8 haemolytically active C5 molecules ml^{-1} were present in the normal peritoneal cell culture media, but none was detected in any of the deficient cell culture media (limits of detection <2% of normal).

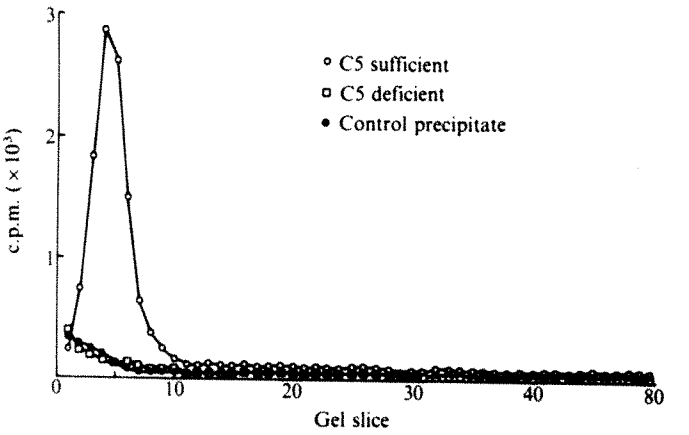

Fig. 1 SDS-polyacrylamide gel electrophoresis of reduced and alkylated C5 protein secreted by mouse peritoneal macrophages from Swiss (C5 sufficient) and A/HeJ (C5 deficient) strains. Confluent resident peritoneal cell cultures were established by placing 12×10^6 cells suspended in Dulbecco's modified Eagle's medium (DMEM) with 20% heated fetal calf serum in 60 mm Falcon plastic dishes. After incubating the cells at 37 °C for 1 h in humidified 5% CO_2 : 95% air to permit adherence, the dishes were washed with DMEM, then fed with DMEM (lacking unlabelled methionine), containing ^{35}S-methionine (80 μCi ml^{-1}), 50 mM ε-aminocaproic acid, 0.2% lactalbumin, 100 U ml^{-1} penicillin and 100 μg ml^{-1} streptomycin. The medium was removed 24 h later, fresh medium containing ^{35}S-methionine was added, and the cultures were incubated for a further 24 h. Medium was collected and centrifuged at 10,000*g* for 10 min to remove floating cells and debris. The cell monolayer was washed three times in phosphate-buffered saline, then lysed in Tris-KCl with 0.01 M Na EDTA, 0.1 M ε-aminocaproic acid, and 0.5% deoxycholate, and 0.5% Triton X-100 buffer[6], then centrifuged at 10,000*g* for 45 min. Total labelled protein was assessed by TCA precipitation of 5-μl aliquots (Table 1). Antiserum to mouse C5 was produced in C5 deficient (B10.D2/old line) mice by immunisation with normal (B10.D2/new line) mouse serum in complete Freund's adjuvant[2,6]. Specific C5 and control (ovalbumin) immunoprecipitates were formed as previously described[6,7], using unlabelled carrier proteins and antisera sufficient to yield 30 μg protein in the precipitates. They were washed, dried and then dissolved by boiling for 2 min in 40 μl buffer consisting of 10 mM Tris, 1 mM EDTA, 1% SDS, 4% 2-mercaptoethanol, 10% glycerol and Pyronine Y. Iodoacetamine (60 mM final concentration) was added and the mixtures incubated at 37 °C for 30 min. Aliquots of 5 μl were removed for estimates of specific incorporation of labelled methionine into C5 antigen (Table 1) and the remainder was applied to 5.6% polyacrylamide, 1% SDS disc gels. Electrophoresis, slicing and counting of samples and analysis of standard gels were performed as previously described[6,7]. Radioactivity in C5 antigen from C5-sufficient (Swiss) cell culture medium (○), C5-deficient (A/HeJ) cell culture medium (□) and control immunoprecipitates (●) are plotted. Peak of radioactivity (○) corresponds to estimated MW of 220,000.

Analysis of the C5 protein produced by normal cells on SDS-polyacrylamide gel electrophoresis showed a single peak of radioactivity (mobility corresponding to MW 220,000) in the extracellular medium (open circle, Fig. 1) and two peaks (MW 201,000 and 34,000) in the cell lysate (open circle, Fig. 2), in agreement with previous findings[6]. Radioactivity in control immunoprecipitates (ovalbumin/anti-ovalbumin) distributed uniformly throughout the gels without recognisable peaks (closed circles). No peak of immunoprecipitable C5 radioactivity was detected extracellularly (open squares, Fig. 1) in any of the C5-deficient cell cultures, but a pattern comparable to the normal was observed in the intracellular compartment (MW 200,000 and 38,000 peaks) (open squares, Fig. 2). Figures 1 and 2 show the result with A/HeJ cells; similar patterns were seen on analysis of the other deficient cell culture media and lysates. Following a 24-h pulse with labelled methionine, a 48-h

SWR	−	80	3,600	7,900	8.9	168
Swiss	+	1,820	2,030	3,380	8.2	100

Sera from mice used for peritoneal macrophage cultures were tested for the presence of C5 antigen by Ouchterlony analysis (results in agreement with findings in ref. 3). Peritoneal cell cultures were established as described in Fig. 1 legend and the extracellular C5 antigen estimated in 125-μl aliquots by subtracting the radioactivity in control (ovalbumin/anti-ovalbumin) immunoprecipitates (mean 427 c.p.m. per 125 μl; range 523 for B10.D2/old line to 308 for AKR) from radioactivity in C5-anti-C5 immunoprecipitates. Intracellular C5 antigen content was estimated from the radioactivity in the high MW pro-C5 peak and low MW peak on SDS-polyacrylamide gel electrophoresis of C5 immunoprecipitates (representative pattern is shown in Fig. 2). To estimate total protein synthesis, TCA precipitation was performed on 5-μl aliquots as described in Fig. 1 legend.

chase of C5-deficient (A/HeJ) cells with medium containing unlabelled methionine resulted in little change in the intracellular C5 antigen pattern on SDS-polyacrylamide gel electrophoresis and no appearance of labelled C5 protein in the extracellular medium. Estimation of pool size and intracellular turnover of C5 antigen cannot be determined, but within the time limits of the experiments, even delayed secretion of labelled C5 antigen was ruled out.

The possibility was considered that macrophages from the deficient strains secreted an unstable C5 precursor protein or a proteolytic enzyme that destroyed normal pro-C5. Accordingly, intracellular C5 protein produced by and prepared from A/HeJ (C5-deficient) cells was incubated for 30 min at 37 °C with unlabelled, C5-deficient (A/HeJ) conditioned medium, C5-sufficient (Swiss) conditioned medium or fresh medium alone. No degradation of labelled pro-C5 (MW ~ 200,000) or the small MW (38,000) proteins was observed on SDS-polyacrylamide gel electrophoresis of the incubation mixtures.

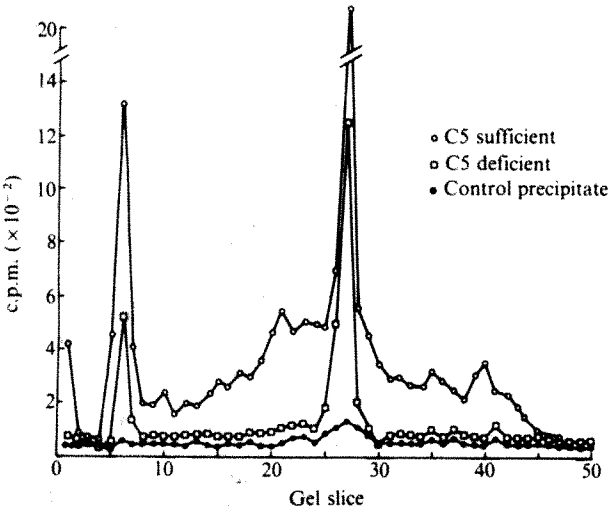

Fig. 2 SDS-polyacrylamide gel electrophoresis of radiolabelled reduced and alkylated C5 protein contained in cell lysates of mouse peritoneal cells from Swiss (C5-sufficient, ○), and A/HeJ (C5-deficient, □) strains. Radioactivity in control immunoprecipitates indicated by closed circles. Estimated MW of the large MW peak was 203,000. In other experiments, estimates ranged from 201,000 to 210,000. The low MW peak was 34,000–38,000. This low MW peak does not correspond in size to a known subunit of C5. A similar pattern of intracellular labelled C5 antigen (two peaks—205,000 and 38,000 MW) was observed in a detergent lysate of Swiss mouse spleen cells obtained from an animal injected with 5 mCi ^{35}S-methionine (supplied by Dr Allen Schwartz).

These data suggest that C5 deficiency in mice is due to a defect in secretion. This may result from a failure of glycosylation as has been proposed as a mechanism for a defect of secretion in certain human immunoglobulin deficiency diseases[8], a mutant mouse myeloma[9] and in normal plasma cells exposed to tunicamycin[10]. A missense mutation could lead to a lack of a suitable site for glycosylation on the C5 polypeptide chain. Alternatively, the defect might reside in synthesis of a protein required specifically for C5 glycosylation or for C5 secretion. In any case, these experiments indicate that the C5 mRNA is translated in cells from several mouse strains genetically deficient in C5, but that the product (pro-C5) is not secreted.

Bombesin (BBS) is a tetradecapeptide originally isolated from amphibian skin[1]. BBS-like immunoactivity is widely distributed in mammalian gut[2–5], and plasma levels have been shown to rise sharply following feeding (ref. 6 and V. Erspamer, personal communication). The physiological actions of BBS are unknown. We have previously shown that the classic gut hormone cholecystokinin (CCK) is a powerful and specific suppressor of food intake[7–9]. Although CCK and BBS lack common amino acid sequences, they have certain common actions on gut viscera[10,11]. We have now shown that BBS also suppresses food intake, and we compare its action with that of CCK.

Eleven male Sprague–Dawley rats weighing 440–520 g were housed and tested in individual cages on an artificial 12-h light cycle. They were maintained on solid food pellets (Purina) overnight and tested with a balanced liquid food preparation (No. 116EC, GIBCO) diluted 1:3 with deionised water. Solid food was removed at 0930 h each morning, and rats were then allowed access to liquid food for 30 min. This pre-deprivation meal of liquid food assured that all rats had eaten a meal shortly before they were deprived of all food at 1000 h. Immediately before the presentation of liquid food in graduated drinking tubes for the test at 1300 h, rats were injected intraperitoneally (i.p.) with 1 ml of one of the following treatments on different days: (1) synthetic BBS in doses of 2, 4, 6, 8, 16 μg per kg body weight, diluted in 0.15 M NaCl; (2) synthetic C-terminal octapeptide of CCK (CCK8) in doses of 0.2, 0.4, 0.7, 1.4, 2.9 μg per kg, diluted in 0.15 M NaCl; (3) equivolumetric controls of 0.15 M NaCl. Food intake was measured at 5 and 15 min, and then at 15-min intervals for the remainder of the 180-min test. The behaviour of each rat was noted[12] during a 4-s interval every minute for the first 45 min of the test. This systematic observation of the behaviours of each animal permitted calculations of the incidences and pattern of the behaviours associated with feeding (exploration, grooming, apparent sleep), so that control and peptide-injected rats could be quantitatively compared; it also permitted the identification of any abnormal behaviour. In all tests, each animal served as its own control; statistical comparisons were made with a matched-pair *t*-test.

BBS and CCK8 each produced a large suppression of liquid food intake across the entire range of doses tested (Fig. 1). The smallest doses of each peptide produced equivalent 15% suppressions: 2 μg per kg BBS reduced food intake from a control of 18.8 ml to 15.9 ml ($P<0.01$); 0.2 μg (~4 Ivy units) per kg CCK8 reduced intake from 18.6 to 15.8 ml ($P<0.01$). The largest doses of each peptide also produced similar suppressions: 16 μg per kg BBS reduced intake from 20.5 ml to 8.1 ml ($P<0.001$); 2.9 μg (~63 Ivy units) per kg CCK8 reduced intake from 17.1 ml to 5.4 ml ($P<0.001$). A comparison of relative effectiveness on a molar basis revealed that the dose of BBS required to suppress feeding by 50% was five times greater than the equipotent dose of CCK8 (Fig. 1).

In a parallel experiment, the effects of BBS and CCK8 were also tested in animals given solid food (Purina rat pellets) following a 7 h (0900–1600 h) food deprivation. Both peptides reduced solid food intake. In these conditions, the lowest dose of BBS, 3 μg per kg, suppressed feeding by 21% (control intake, 2.8 g; intake after BBS, 2.2 g; $P<0.05$). The lowest dose of CCK8, 1.1 μg (~24 Ivy units) per kg suppressed feeding by 30% (from 2.7 g to 1.9 g; $P<0.01$). The largest dose of BBS tested, 6 μg per kg, suppressed feeding by 50% (from 2.8 g to 1.4 g; $P<0.01$). The largest dose of CCK8, 3.8 μg (~84 Ivy units) per kg, suppressed feeding by 77% (from 2.6 g to 0.6 g; $P<0.001$).

The actions of BBS and CCK8 were similar in two respects. Both peptides suppressed feeding rapidly, with maximum reductions occurring during the first 15 min after injection. In addition, both peptides produced transient suppressive effects: even after large doses, cumulative food intakes of peptide-injected rats had returned to normal levels within 120 min. However, the actions of the two peptides differed in one respect. Although both suppressed liquid and solid food intakes, CCK8 was two to five times as potent in suppressing liquid food intake as it was in suppressing solid food intake, a differential we have noted previously[7]. In contrast, BBS suppressed solid and liquid food intakes equally. Thus, the potency of CCK8 varied according to the physical characteristics of the test diet, whereas the potency of BBS did not.

As BBS suppressed solid as well as liquid food intakes, the suppression was not achieved through some interference with the motor acts required for licking. Furthermore, the largest dose of BBS tested had no effect on water consumption after the minimal water deprivation (6 h) required to achieve reliable intakes. Thus, BBS preferentially reduced feeding, not drinking, even when the same motor act (licking metal spouts for liquid food or water) was required for either ingestive behaviour; this differential strongly suggests that BBS did not reduce feeding simply by producing some generalised discomfort. Several further observations also indicated that BBS did not cause illness or distress. First, the rats never seemed acutely or chronically ill, and they gained weight normally during 8 months of frequent testing. Second, after injections of BBS, rats always began eating eagerly; they merely stopped sooner. Thus, no statistically significant differences in food intake between BBS- and saline-injected rats occurred during the first 5 min of feeding, but BBS-injected rats ate much less than saline-injected rats between 5 and 15 min of the test. This ineffectiveness of BBS in preventing or slowing the early phase of feeding was not an artefact of the time required for the distribution of exogenously injected BBS as it occurred whether the peptide was injected immediately before, 5 min before, or 15 min before food presentation. Thus, BBS preferentially acted to enhance satiety by shortening the meal; it did not prevent or delay the onset of a meal, nor did it slow the initial phase of eating. Third, analysis of the minute-by-minute behavioural data revealed that the only significant behavioural change produced by BBS was a decrease in the incidence of feeding (Table 1).

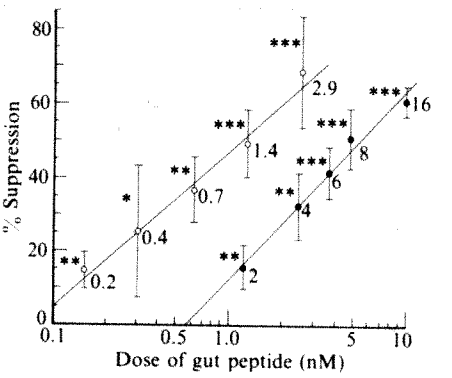

Fig. 1 Suppression of liquid food intake in rats ($n=11$) during the first 15 min after i.p. injections of various doses of BBS (●) or CCK8 (○). The figure shows mean per cent suppressions and s.e.m. compared with intake on control tests. Doses of each peptide are in μg per kg. Doses of the two peptides on the abscissa are arranged along a molar logarithmic scale. Control intakes of liquid food ranged from 13.7 to 20.5 ml (mean 18.1 ml, s.e.m. 0.3 ml). * $P<0.05$, ** $P<0.01$, *** $P<0.001$, statistical differences from respective 0.15 M NaCl controls. Correlation coefficients (Pearson product–moment): for BBS, $r=0.91$ ($P<0.025$); for CCK8, $r=0.97$ ($P<0.005$). Slopes of the regression lines were not significantly different[31] ($t=0.22$, $P>0.05$).

These data demonstrate that BBS did not reduce food intake simply by causing a generalised disruption of behaviour; rather, it produced a selective suppression of feeding, a quality which one would anticipate in a natural satiety signal. Furthermore, in no instance did BBS elicit any abnormal behaviour. Finally, in our unpublished observations, doses of BBS as high as 128 μg per kg have failed to produce any evidence of illness or distress in similar test condictions. Although intracisternal BBS can reduce core body temperature of cold-exposed rats[13], we found no change in core body temperature, as measured by rectal thermoprobe, 15 or 30 min after i.p. injections of doses of 4–32 μg per kg, the times when suppression of feeding was maximal.

The mediation of the satiety action of BBS is unknown. The slopes of the regression lines drawn for the BBS and CCK8 dose–response curves were not significantly different statistically (see Fig. 1). Parallelism of curves is consistent with but not proof of the same mechanism of action[14]. This parallelism might be explained if exogenous BBS produces its satiety effect simply by releasing endogenous CCK[10,15–17]. However, as described above, comparison of the dose–response curves for liquid and solid foods revealed a situation in which the effects of BBS and CCK8 diverged, depending on the physical characteristics of food ingested; this divergence demonstrates that the satiety

Table 1 Incidence of behaviours occurring after i.p. injection of BBS (8 μg per kg) or vehicle control (0.15 M NaCl) in 11 rats

	Feeding	Exploration, grooming	Apparent sleep	Miscellaneous
Control	15	19	65	1
BBS	5*	23	71	1

Incidences are expressed as mean % of the total number of behavioural observations carried out. During the first 45 min of the test the only statistically significant effect which BBS produced was a reduction in the incidence of feeding.

* $P < 0.001$, BBS compared with control. All other BBS–control comparisons were nonsignificant ($P > 0.4$).

action of exogenous BBS cannot be mediated solely by endogenous CCK. Three observations of visceral gut actions of BBS relate to this point. (1) In humans, Basso *et al.*[11] have shown that the addition of secretin to a slow intravenous infusion of BBS caused a partial inhibition, rather than a potentiation, of BBS-induced pancreatic amylase output, suggesting that secondarily released CCK is not the major mediator of BBS-induced amylase output in these conditions. (2) Although enterectomy abolishes BBS-induced pancreatic protein secretion in the dog[15] it does not affect this action in the rat[18]. (3) BBS powerfully stimulates amylase release from *in vitro* preparations of rat pancreatic fragments[19,20] or dispersed acinar cells[21]. These findings strongly suggest that BBS can directly stimulate traditional CCK target tissues.

We conclude that BBS is a putative satiety signal. The existence of at least one unidentified gastric satiety signal has recently been demonstrated in the rat[22,23]. We have shown that the action of this gastric signal does not depend on vagal innervation[24], and may therefore be hormonal in nature. As it is present in large quantities in gastric mucosa[4], BBS is a candidate for this unidentified satiety signal.

We have not determined how the amount of BBS required to elicit satiety in this study relates to the amount and pattern of BBS released by a normal meal, nor how BBS may interact with other putative satiety signals, such as CCK. Finally, the site of action of BBS when it alters satiety behaviour is unknown, but it is of interest that BBS immunoactivity[4,5,25], like that of CCK[26–30], is present in large quantities in the brain.

We thank F. Gutman for assistance and J. D. Falasco, C. F. Martin, H. Pringle, K. J. Simansky and G. P. Smith for critical readings of the manuscript. Synthetic BBS was from R. de Castiglione (Farmitalia) and CCK8 was from M. Ondetti (Squibb). The research was supported by the American Philosophical Society, the Royal Society of Medicine Foundation, the USPHS (NIAMDD and NIMH) and the MRC.

Human β-thromboglobulin inhibits PGI_2 production and binds to a specific site in bovine aortic endothelial cells

W. Hope*, T. J. Martin*, C. N. Chesterman† & F. J. Morgan‡

Blood platelets have a major role in haemostasis through their aggregation and adherence to the damaged vessel wall. During this process, platelet granular constituents are released. Although the functions of many of these release products are well known, biological functions of some well defined platelet specific proteins have not been determined. This category includes platelet factor 4 (PF4) and β-thromboglobulin (βTG), both small proteins of molecular weight 30,000–36,000 (refs 1, 2) which are stored in the α granule of the platelet and have not been detected in any other tissue. βTG is composed of four identical noncovalently bound subunits and its amino acid sequence is significantly homologous with that of PF4 (ref. 3). Although PF4 possesses a marked ability to neutralise heparin, no physiological or pathophysiological role has been attributed to either protein. The discovery of prostacyclin (PGI_2) has led to a reappraisal of the factors regulating haemostasis and especially of the role of the vascular endothelium in preventing platelet adherence and aggregation[4–6]. The initial action of PGI_2 on the platelet is to stimulate adenylate cyclase[7–9], and it is the most potent inhibitor of platelet aggregation yet discovered. Also, cultures of arterial and venous endothelial cells have been found capable of producing PGI_2 (refs 10, 11). We now report results indicating that βTG reduces the production of PGI_2-like activity in cultured bovine endothelial cells, which are shown to possess a specific receptor for βTG. The characteristics of this receptor suggest that βTG may act locally at high concentrations to favour platelet aggregation by diminishing PGI_2 production.

Monolayer cultures of aortic endothelial cells were established from bovine aortas obtained from animals immediately after slaughter and processed within 1 h. Endothelial cells were prepared from the bovine aorta by collagenase digestion according to the method of Gimbrone *et al.*[12], and grown in plastic culture bottles in medium RPMI-1640 with 40% fetal calf serum. Small groups of cells became established, grew to near confluence within about 1 week and were subcultured by washing the monolayer surface with 0.02% EDTA followed by incubation in 0.025% trypsin–EDTA for 1–2 min. Complete culture medium (5 ml) was then added, and the cells were washed and resuspended in medium to be plated out in fresh vessels. All experiments were carried out on the first to the fourth subcultures. For studies of PGI_2 production, cells were suspended as in routine subculture, but were washed once more before resuspension in a buffered salt solution (BSS). Substances

to be tested were added to this cell suspension at the desired concentrations, and an aliquot of the endothelial cell suspension containing a known number of cells was tested for its ability to inhibit arachidonic acid-induced aggregation of human blood platelets. Preliminary experiments had shown that incubation of cells with indomethacin (14 μM) or tranylcypromine (500 μM) abolished the ability of endothelial cells to inhibit platelet aggregation. Furthermore, incubation of endothelial cell cultures with ^{3}H- or ^{14}C-labelled arachidonate, followed by extraction and this layer chromatography of acidified medium, showed that the major labelled prostanoid product was 6-keto-prostaglandin $F_{1\alpha}$, which is the stable degradation product of the labile PGI_2. No significant PGE_2 was formed in these conditions of short incubations.

Following incubation with human βTG, significantly more endothelial cells are required for complete inhibition of aggregation than in control incubations (Table 1). PF4, PGE_2, isoprenaline, serotonin and nicotine had no effect in this system. The effect of βTG on endothelial cells was seen at concentrations which are of the same order as those in serum or platelet-rich plasma (PRP) during collagen-induced platelet aggregation[13]. βTG (10 μg ml^{-1}) had no direct effect on the threshold concentration of arachidonate required to induce aggregation, nor did it influence the ability of synthetic PGI_2 to inhibit arachidonate-induced aggregation. These findings indicate that βTG decreases the production of PGI_2-like biological activity by endothelial cells.

Table 1 Effect of incubation with βTG and other substances on endothelial cell numbers required to inhibit platelet aggregation

Treatment	Concentration	Relative no. of endothelial cells to inhibit aggregation		
Control	—	1.00	(23)	
βTG	1 μg ml^{-1}	2.30 ± 0.93	(5)	$P<0.05$
	2 μg ml^{-1}	2.02 ± 0.43	(5)	$P<0.005$
	5 μg ml^{-1}	4.60 ± 0.57	(3)	$P<0.02$
PF4	10 μg ml^{-1}	1.0	(3)	
PGE_2	10^{-6} M	1.0	(1)	
Serotonin	5×10^{-5} M	1.0	(3)	
Isoprenaline	10^{-6} M	1.16 ± 0.05	(3)	NS
Nicotine	10^{-6} M	1.0	(4)	

Results are from 23 individual experiments studying the effects of various agents on the number of endothelial cells required to inhibit arachidonate (AA)-induced aggregation of human blood platelets. Blood was drawn from normal volunteers into 3.8% sodium citrate (1:9 v:v). PRP was prepared by centrifugation at 200*g* for 10 min at room temperature. The threshold concentration of AA (Sigma) required to cause platelet aggregation was determined with 0.4 ml of PRP in a Payton dual-channel aggregometer; normal subjects with no recent aspirin ingestion required 0.4–1 mM AA. Endothelial cell suspensions were prepared by subculturing cells from the primary to the fourth subculture. After the standard subculturing procedure (see text) cells were washed once in phosphate-buffered saline (PBS) and resuspended in BSS of the following composition: Tris 15 mM, NaCl 120 mM, KCl 4 mM, $MgSO_4$ 1.6 mM, NaH_2PO_4 2 mM, $CaCl_2$ 1.2 mM, glucose 10 mM, human serum albumin 0.1%, at *p*H 7.4. Cells were counted in a haemocytometer, and suspended to concentrations of $1–5\times10^6$ per ml. Duplicate incubations of cell suspensions (0.5 ml) were carried out in 10-ml plastic tubes in a shaking incubator at 37 °C. The various treatments were added in BSS, and after at least 15 min incubation, samples of the incubations were tested for their ability to inhibit AA-induced platelet aggregation. βTG was prepared[1,2] from the platelet release products of platelet concentrates and PF4 from the supernatant of outdated platelet concentrates, as previously described[19]. Aggregation inhibition by the incubated cells was tested as follows. To 0.4 ml PRP in an aggregometer tube was added 10 μl of cell suspension or of a dilution made in BSS. Dilutions were made until the minimum amount required to inhibit platelet aggregation was determined, from which the number of cells required to inhibit aggregation was calculated. In each experiment the procedure was repeated for control and treated cells at least twice. Each experiment was completed within 2 h of subculture. In all reported experiments the cell numbers (control and treated) required to inhibit aggregation remained constant throughout the experiment. When this was not the case, experiments were discontinued. The numbers of cells (control incubations) required to abolish threshold AA-induced aggregation varied from 1 to 80×10^3 among the 23 different experiments; in all except 4 experiments a single treatment was tested. Each treatment is expressed as the relative number of cells (±s.d.) required to abolish AA-induced aggregation compared with the control experiment which is expressed as unity; the number of individual experiments is given in parentheses. Statistical analysis was carried out using a logarithmic transformation of the relative cell numbers (paired *t*-test). With PF4, PGE_2, serotonin and nicotine, the effective dilution never differed from that of the control. NS, not significant.

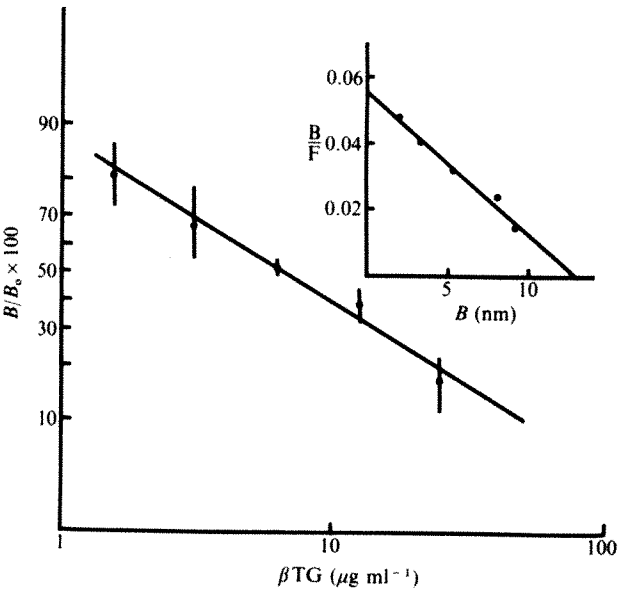

Fig. 1 Specific binding of ^{125}I-βTG to bovine aortic endothelial cells. Cells from the first subculture were dispersed (see text), washed twice with PBS and resuspended at a concentration of 5×10^6 cells ml^{-1} in BSS (see Table 1). Binding experiments were carried out for 1 h at 25 °C in 10-ml plastic tubes with vigorous shaking. Incubations in duplicate consisted of 0.3 ml of cell suspension and 0.2 ml BSS containing ^{125}I-βTG (55,000 c.p.m. per tube) and increasing amounts of unlabelled βTG or other substances to be tested. βTG was labelled with ^{125}I using the lactoperoxidase method as described previously[20]; specific activity in this experiment was 200 μCi per μg, and varied down to 50 μCi per μg in other experiments. At 1 h 200-μl duplicate samples were removed from the incubation, and centrifuged (Beckman Microfuge, Model B, 5 min, 10,000*g*). The supernatants were removed, the tips of the tubes containing the cell pellet cut off and the bound radioactivity estimated in a Packard spectrometer with 75% efficiency for counting ^{125}I. Nonspecific binding (NSB) was measured as radioactivity bound in the presence of excess βTG (50 μg ml^{-1}) and was subtracted from the total radioactivity bound to obtain specific binding. Specific binding of ^{125}I-βTG in the absence of unlabelled βTG (B_0) was 5.1% and the NSB 2.0% in the experiment shown; in other experiments specific binding was between 4 and 9%, and the NSB varied from 0.5 to 2%. The displacement curve is expressed in terms of the ratio of specific binding at a given dose (B) to the specific binding in the absence of added βTG (B_0) plotted on a logistic scale[21]; each point represents the mean of four determinations, and the bars 1 s.d. There was no displacement of ^{125}I-βTG by PF4 (100 μg ml^{-1}), hen egg lysozyme (100 μg ml^{-1}) or human leukaemia lysozyme (100 μg ml^{-1}). Inset: Scatchard plot derived from the displacement curve shown. The dissociation constant (K_d) was estimated as 2.3×10^{-7} (95% confidence limits, 1.7–2.9) and the number of receptors per endothelial cell at 2.6×10^6 (95% confidence limits, $2.1–3.1\times10^6$). B/F, Bound/free βTG.

This effect of βTG suggested that the endothelial cell might possess a cell-surface receptor for βTG. The experiment shown in Fig. 1 indicates the presence of a specific receptor for βTG on bovine aortic endothelial cells. Competition for binding of ^{125}I-labelled βTG was by βTG only and not by PF4 in several-fold excess, nor by other basic proteins, such as hen egg lysozyme (Worthington) or human leukaemic lysozyme[14]. The concentrations of βTG required for half-maximal inhibition of binding are similar to those required to inhibit PGI_2 formation by endothelial cells. In four separate experiments, the average dissociation constant (K_d) was 1.7×10^{-7} M and the number of receptors per cell was calculated as 2×10^6.

Although the methods used to measure the βTG response in endothelial cells do not enable us to relate the effect directly to the binding to endothelial cells, nevertheless, the co-existence of

Nature Vol. 282 8 November 1979

a specific binding site and the biological effect strongly suggests that the two are related. Apart from studies of drugs[10], there is little information on other factors which might regulate PGI_2 production by endothelial cells. MacIntyre *et al.*[15] found that a factor in cell-free plasma stimulated PGI_2 production by pig aortic endothelial cells. Thrombin, trypsin and a calcium ionophore have been shown to stimulate PGI_2 production[16], and in experiments similar to our own, plasma low-density lipoproteins have been found to decrease production of PGI_2 activity by human umbilical vein endothelial cells[17]. The present results suggest that βTG may be involved in the control of haemostasis. During vascular wall injury, which is followed by platelet adhesion and aggregation—processes which would both be inhibited by PGI_2—release of βTG could prevent PGI_2 formation by adjacent endothelium, and allow the healing process to continue. In this situation βTG would be acting locally, and the dissociation constant derived from our experiments would be consistent with this action, as concentrations of this order are exceeded during platelet aggregation and release[13]. A local mode of action requires a binding site with an affinity some orders of magnitude less than the normal plasma level of 20 ng ml^{-1} (approximately 0.7 nM)[13]. Bovine endothelial cells were washed free of fetal calf serum before use in the experiments described above. Although bovine βTG has not been reported it is likely that such a protein exists. In this case, although the measured affinity suggests that a significant proportion of bound βTG would dissociate during the washing procedure, the activities measured here may be diminished to some extent by residual occupancy of receptor sites.

It is of particular interest that the distinct but closely related platelet protein, PF4 (ref. 3), neither competes for receptor binding nor has a similar biological effect. βTG has been isolated in two different forms, the preparation used in these experiments corresponding to that originally described by Moore *et al.*[1], its structure has been completely determined[3]. The other preparation, which has been designated low-affinity PF4 (LA-PF4) by Rucinski *et al.*[18], and has an additional NH_2-terminal tetrapeptide but is otherwise identical to βTG, needs to be investigated for probable similar activity. Finally, if βTG interaction with receptor is linked to the effects of the protein on PGI_2 formation, it is important to determine precisely the biochemical events occurring between receptor interaction and PGI_2 production in endothelial cells.

We thank Dr R. E. Canfield for a gift of human leukaemia lysozyme. This work was supported by grants from the National Health and MRC, the National Heart Foundation of Australia, and the Australian Tobacco Research Foundation.

Inhibition of platelet thrombus formation by chlorpromazine acting to diminish haemolysis

G. V. R. Born

Department of Pharmacology, King's College, London WC2, UK

A. Wehmeier

Department of Pharmacology, University of Cambridge, Cambridge, UK

There is increasing evidence[1] that the sudden, unpredictable event initiating myocardial infarction is fissuring of an atherosclerotic plaque. The resulting haemorrhage into the arterial wall produces obstructive platelet thrombi, just as arterial haemorrhages elsewhere produce haemostatic platelet plugs. It has been suggested[1] that such platelet aggregation depends on ADP originating in red cells which are subjected to excessive haemodynamic stress at the site of haemorrhage. The release of ADP from red cells has been demonstrated *in vitro* in equivalent conditions of shear stress[2,3]; and other mechanisms, such as activation by collagen, cannot account for the rapidity with which the platelets react[4]. One of us (G.V.R.B.) has suggested that drugs capable of counteracting haemolysis[5] might diminish the activating effect of erythrocytes on platelets[6] and so inhibit their aggregation as thrombi. Thus, chlorpromazine, added to human blood at concentrations which diminish haemolysis but do not directly affect platelet aggregation[7,8], prolonged the 'bleeding time' from small holes in artificial vessels where extravasation is terminated, as in living arterioles, by aggregated platelets[9]. The bleeding time was also prolonged by apyrase, consistent with the conclusion that the chlorpromazine acted through decreasing plasma ADP. We show here that this occurs through the anti-haemolytic action of chlorpromazine.

Venous blood was obtained from apparently healthy volunteers who had not taken drugs known to affect platelet reactions. The blood with heparin (20 or 50 units ml^{-1}) as anticoagulant was pumped at 37 °C from a syringe through polyethylene tubing of 280 μm internal diameter and 50 cm long. The flow rate was 0.17 or 0.21 ml min^{-1} (both rates gave the same results) and the pressure was about 300 mm Hg. The duration of 'bleeding' from a small cut through about one half of the circumference of the tube and 30 cm from its end was determined up to 600 s. Free haemoglobin was determined by the cyan-methaemoglobin method in blood from the syringe ('unsheared') and from the end of the tube ('sheared'). Most determinations on unsheared blood were bracketed between two on sheared blood.

It was confirmed[9] that chlorpromazine added to the syringe blood for 45 min prolonged the bleeding time significantly, and did so more at 5 or 10 μM than at 50 μM (Table 1).

Unsheared blood contained low concentrations of free haemoglobin which were not changed significantly by chlorpromazine at 5 or 10 μM but were increased by drug concentrations of 50 μM (Table 1). In sheared blood free haemoglobin concentrations were significantly higher than in unsheared blood in the absence of chlorpromazine, which decreased the free haemoglobin significantly at 5 μM and just significantly at 10 μM but not at 50 μM. The differences in free haemoglobin between unsheared and sheared blood were decreased highly significantly by chlorpromazine but less at 50 μM than at 5 or 10 μM.

Our interpretation that the prolongation of bleeding time by chlorpromazine depends on its effect on red cells is tenable only if direct inhibition of platelet aggregation could be excluded. In three experiments it was confirmed (see ref. 8) that chlorpromazine incubated at these concentrations in blood or pla-

Significances of differences from controls: *$P < 0.05$; †$P < 0.005$.

telet-rich plasma for increasing lengths of time had no significant effect on the velocity of primary aggregation[10] induced by ADP. Secondary aggregation associated with the release reaction is not inhibited by chlorpromazine at 5 μM, slightly at 10 μM and more at 50 μM (ref. 8), whereas the bleeding time was more prolonged and haemolysis more strongly inhibited at 5 μM and 10 μM than at 50 μM.

These observations establish that low concentrations of chlorpromazine greatly diminish haemolysis of blood during shear-flow but not when at rest. This strongly supports the proposition[9] that chlorpromazine increases the bleeding time through its anti-haemolytic effect. In the absence of chlorpromazine, haemolysis would have given initial plasma concentrations of ADP and ATP of 0.05 and 0.40 μM respectively. Because the dephosphorylation in blood of ATP to ADP is much faster than that of ADP to AMP[11], the concentration of ADP was probably higher and amply sufficient to activate platelets[12]. It can be concluded, therefore, that ADP released from red cells lysed by haemorrhagic shear-flow can account for haemostatic and thrombotic platelet aggregation.

The haemolysis caused by shear-flow was strikingly decreased by chlorpromazine. On the assumption that these decreases in the release of haemoglobin were accompanied by corresponding decreases in the release of ADP and ATP, it may be concluded that the increases in bleeding time brought about by these concentrations of chlorpromazine are explained by the very much lower concentrations of ADP available for activating the platelets.

This explanation is supported by the apparently paradoxical diminutions in the effect on both bleeding time and haemolysis when chlorpromazine was present at the higher concentration of 50 μM. Chlorpromazine, like other drugs (see ref. 5), is anti-haemolytic at low but strongly haemolytic at higher concentrations. It seems, therefore, that in our experiments chlorpromazine at 10 μM was almost maximally anti-haemolytic whereas at 50 μM the opposing haemolytic effect began to show itself also.

While the blood was in the syringe reservoirs at 37 °C it haemolysed to a small extent (0.23 ± 0.02% in blood from 8 donors) after 2–3 h. In such a long time the adenine nucleotides released from lysed red cells are enzymatically dephosphorylated[11] so that there would be no free ADP to activate the platelets in the blood reservoirs.

Red cells undergo the greatest haemodynamic stress near the vessel walls, where flow velocity is slowest. Therefore, the concentration of released ADP is greatest near the walls which is where the platelets have to be activated for their haemostatic function.

The wall shear stress in these artificial vessels was about 50 dyn cm^{-2}, which is similar to that in living arterioles[13]. This stress, even when acting for considerably more than 10 s, is too small to activate platelets directly[14]. The wall shear stress is higher by at least two orders of magnitude at sites of arterial haemorrhage[3]. This stress is too brief to activate platelets directly[14]. Their activation can now be accounted for by assuming the local lysis of a very small proportion of red cells.

There is evidence[15,16] which can be interpreted[17] to suggest that chlorpromazine and at least one other phenothiazine administered for clinical purposes are capable of protecting against myocardial infarction. As the concentration of chlorpromazine in patients' plasma[18] is about one order of magnitude lower than that which greatly prolonged the *ex vivo* bleeding time, blood concentrations of chlorpromazine produced clinically may protect against myocardial infarction by the anti-haemolytic mechanism.

All this evidence supports the suggestion[1,9,17] that drugs which have the effect described in this paper for chlorpromazine may be found to ameliorate or prevent arterial, for example coronary, thrombosis when it is induced by haemorrhage into atheromatous lesions or by other haemodynamic stresses severe enough to cause haemolysis.

We thank Miss Margaret Hickman for technical assistance, the German National Scholarship Foundation for supporting A.W. and the Fritz Thyssen Foundation for supporting this research.

Electron microscope evidence for an 80 Å unit in collagen fibrils

D. A. D. Parry

Department of Chemistry, Biochemistry and Biophysics, Massey University, Palmerston North, New Zealand

A. S. Craig

Applied Biochemistry Division, DSIR Palmerston North, New Zealand

Connective tissues are composite structures containing collagen, elastin, glycosaminoglycans, minerals, water and other minor components[1,2]. In all cases the collagen exists predominantly in fibrillar form. The size distribution of the fibrils does, however, vary markedly with both age and the mechanical requirements of the tissue[3]. Little is known about the mechanism of fibril formation *in vivo*, although some information is now available from *in vitro* polymerisation studies[4]. We have now collected new and extensive electron microscope data on the size of collagen fibrils from tendon, skin, cornea and other tissues from both fetal and immature animals. The results reported here show that the diameters of the collagen fibrils thus measured lie close to a multiple of 80 Å, a result which may be simply and readily interpreted in terms of the collagen microfibril and its mode of packing.

It is generally accepted that collagen fibrils are constructed from molecules which are axially staggered with respect to one another by about 668 Å (or a multiple thereof)[5–9]. The nature of the lateral packing of the molecules is controversial, however. The first significant packing model proposed was that of Smith[10], who suggested that a five-stranded microfibril of diameter ~35 Å could exist in connective tissues. Improved X-ray data from orientated specimens of moist rat-tail tendon subsequently became available and these confirmed that a unit of diameter ~38 Å was indeed present[11], thus providing strong support for the Smith microfibril. Further interpretation of the X-ray patterns[12–14] showed that the unit cell was a slightly sheared tetragonal cell of lateral side ~77 Å and that each unit cell contained four microfibrils related to one another by a 4_3 screw axis. Others have since suggested alternative schemes for the packing of collagen molecules in the fibril (see for example refs 15–17) and in each instance it is claimed that the X-ray data are consistent with the proposed scheme. Electron microscope evidence has therefore been sought to differentiate between the various models which have been put forward. At the present time, however, no conclusive evidence has been obtained from transverse sections which supports a regular arrangement of collagen molecules or groupings of collagen molecules though the possibility remains that the preparative procedures used have not preserved the *in vivo* lattice structure.

It has been suggested by Fraser *et al.*[18] that if the structure of small collagen fibrils, which appear circular in section, is indeed based on a lateral repeating unit of four microfibrils related to one another by a 4_3 screw axis, then their diameters should be multiples of about 85 Å. This value is calculated on the basis of the most symmetrical arrangement of lateral repeating units, that is, an $n \times n$ array. Fraser *et al.*[18] noted that the preservation of the structure of small fibrils would probably be insufficient to distinguish between $n \times n$ unit cell fibrils and helical fibrils, both of which would appear to be circular in cross-section. Parry *et al.*[19] simultaneously reported that the mean diameter of the collagen fibrils from 10 tissues, each of which had a sharp unimodal distribution of fibril diameters, occurred at multiples of about 80 Å. We present new data which support those preliminary observations and which imply that the unit cell and microfibrillar structure proposed for tendon are likely to be a feature of all other connective tissues as well.

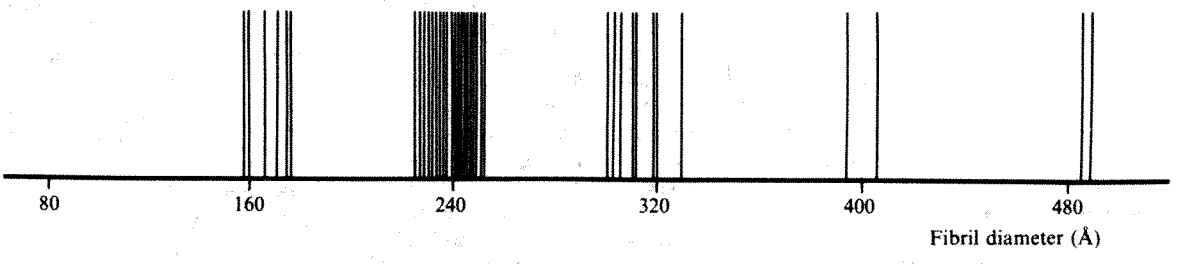

Fig. 1 Graphical representation of the values listed in Table 1. It can be seen that the diameters of the collagen fibrils fall in discrete clusters separated from one another by 80 Å. The clusters are centred on values of about 160, 240, 320, 400 and 480 Å.

Let us consider the conditions in which quantum jumps of 80 Å in fibril diameter might most easily be observed. Firstly, the magnification of the electron microscope must be known precisely for each set of micrographs taken, the calibration being based, say, on a replica grating. Secondly, the mean value of many diameter measurements ($\geq$100) taken from the original electron micrographs using a binocular microscope, will only be close to the true diameter of each and every fibril (and hence be meaningful) if the distribution of collagen fibril diameters is both unimodal and sharp. This assumes that the spread of measured values does not represent the true range of collagen fibril diameters but arises entirely from the inherent difficulty of measuring and defining the fibril periphery after standard electron microscopic preparative procedures have been used.

The standard deviation for each distribution of collagen fibril diameters has been calculated and where this is <35 Å it has been considered that the distribution is sufficiently sharp to represent a population of uniform diameter fibrils. The stipulated standard deviation, being less than (80/2) Å, gives a criterion on which to exclude those fibril diameter distributions which are likely to be comprised of two or more populations of fibrils differing in diameter from one another by a multiple of 80 Å. Such distributions will have a mean diameter dependent solely on the relative proportions of the various populations of fibrils making up the overall distribution.

Measurements made in this work, together with those of Parry *et al.*[19], are shown in Table 1 and Fig. 1. The results show that the diameters of small collagen fibrils taken from a variety of diverse connective tissues have values which are close to a multiple of about 80 Å. It is important to note that Table 1 contains every piece of data that we have collected, subject only to it satisfying the stated criteria. We are aware of many values quoted in the literature which relate to the diameters of small collagen fibrils and while many of these values fall close to a multiple of 80 Å (see for example ref. 20), others do not. We believe that it is probable that most, if not all, of these values do not satisfy one or both of the criteria listed earlier.

It therefore seems appropriate to suggest that the 80 Å unit cell first seen in tendon from X-ray diffraction analyses and now shown by electron microscopy to exist also in tissues such as skin, cornea and endoneurium, as well as tendon, may have a similar interpretation in all cases, that is, each 80 Å unit contains four microfibrils related to one another by a 4_3 screw axis.

We believe that the diameters of all collagen fibrils, irrespective of their size, may be multiples of about 80 Å. This cannot, of course, be easily proved in the cases of broad distributions of collagen fibrils as a meaningful mean diameter (within the limits imposed by our criteria) can no longer be calculated and also because any slight ellipticity of a single fibril in cross-section will disguise its true diameter. Also the shape of the collagen fibrils in cross-section often become less regular as the fibrils increase in diameter and as the tissue ages[21,22]. Nonetheless we propose, on the basis of these results, that all fibril diameter distributions, whether they originate from a fetal, mature or senescent tissue, are constructed from changing populations of collagen fibrils whose diameters are multiples of about 80 Å.

Competence for genetic transformation in pneumococcus depends on synthesis of a small set of proteins

D. A. Morrison & M. F. Baker

Department of Biological Sciences, University of Illinois at Chicago Circle, Chicago, Illinois 60680

In bacterial genetic transformation the uptake of DNA and its integration into the resident chromosome is dependent on a special cellular state, termed competence. In those species where appearance of competence has been studied, specific (but often poorly defined) growth conditions lead to a simultaneous development of competence in a substantial fraction of the cells in a culture. In *Bacillus subtilis*[1–4], and in *Haemophilus* species[5,6], competence appears in the stationary phase of growth or in certain other growth-limiting conditions[5,6]. *Streptococcus pneumoniae* (pneumococcus) is perhaps unusual in that virtually all cells of a culture become competent[7,8], for a short period at a specific cell density during logarithmic growth, without perturbing the growth rate[9]. The synchronous appearance of competence in pneumococcal cultures results from an autocatalytic effect of a small protein[10] released by the cells that induces competence[11,12]. The response to competence factor has been shown to require protein synthesis[13]. We report here additional information on the nature of competence in pneumococcus: pulse-labelling studies show that for the brief period of competence protein synthesis is restricted to a few specific polypeptides.

Figure 1 displays the patterns of proteins pulse-labelled with ^{35}S-methionine at successive intervals before, during, and after competence in a culture transferred to a low-methionine labelling medium after stimulation by endogenous competence factor. Also shown is the level of competence achieved by the end of each labelling pulse, measured genetically. The fluorogram reveals two prominent features of protein synthesis associated with the appearance of competence. First, there is a striking decrease in the synthesis of most proteins, including all the major labelled bands. Second, during the middle portion of the competence period, protein synthesis, although normal in total amount, is limited to about 11 principal species. The approximate molecular weights of these are: 14.5K, 16K, 18K, 19.5K, 31K, 34K, 36K, 41K, 45K, 50K, and 52K. Only one of these, about 19,500 MW, is clearly absent from the pattern of non-competent cells at this level of resolution. Critical comparison of lanes in the original film suggests that at least three others are new, but a second dimension will be needed to verify this. Thereafter, as competence declines, the labelling of these bands decreases, and synthesis of the normal complement of proteins resumes.

In a second experiment, the synthesis of the same set of proteins appeared in samples of a culture that became competent, but not in samples of a parallel culture grown with trypsin to inactivate the intercellular action of competence factor (Fig. 2).

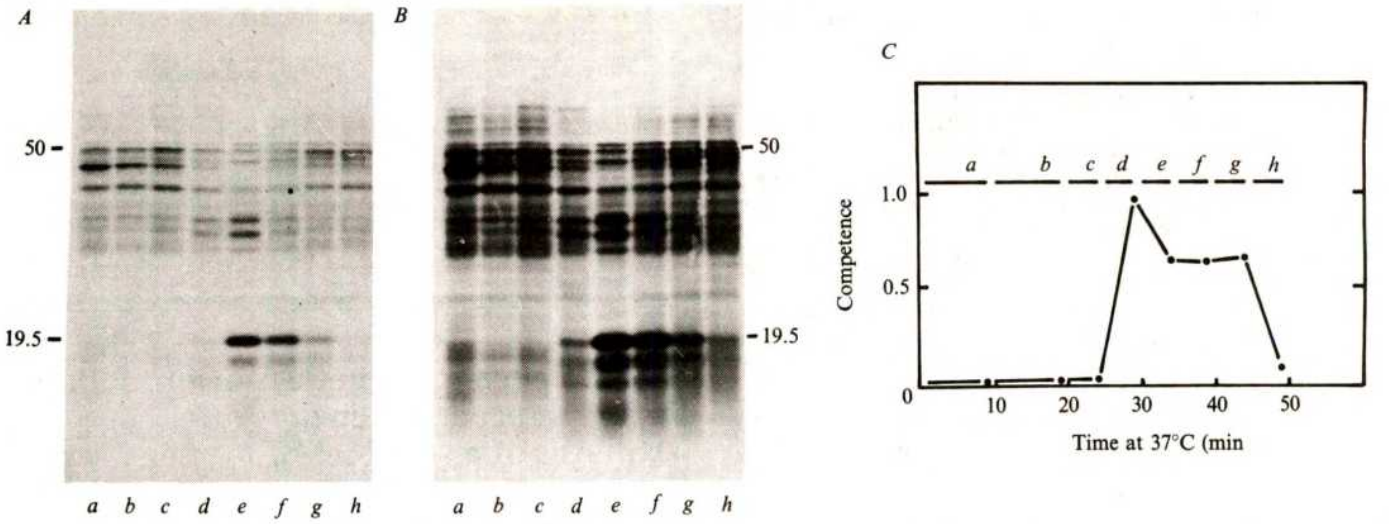

Fig. 1 Pulse-labelled proteins of a pneumococcal culture developing competence for genetic transformation. A growing culture of DP1700 was chilled about 25 min before the peak of competence, concentrated to 4×10^8 colony-forming units per ml and frozen[14]. A sample was thawed at 0 °C, washed and resuspended in an equal volume of labelling medium[16]. During incubation of this sample at 37 °C, aliquots were labelled with ^{35}S-methionine (12 μCi ml^{-1}) for periods, shown by bars in panel *C*, then assayed for competence by dilution of a portion into broth containing 2 μg ml^{-1} Ery-r transforming DNA, and prepared for electrophoresis. Cells were chilled, washed, and resuspended in 10 mM Tris, *p*H 6.8, 1 mM EDTA, 5 mM $MgCl_2$, 0.1% Triton X-100, 10 μg ml^{-1} DNase I, 50 μg ml^{-1} RNase, and lysed at 37 °C (10 min). Lysates, boiled with 1% mercaptoethanol and SDS, were applied to a 12% slab gel. The $0.15 \times 10 \times 14$ cm polyacrylamide gel used the SDS disc buffer system of Laemmli[17], and fluorography was as described by Laskey and Mills[18], with Kodak Xomat XR-1 film. Each well of the slab gel contained 10^4 c.p.m. incorporated ^{35}S. *A*, Fluorogram of samples labelled for the periods indicated in *C*, 6-h exposure. *B*, Same as *A* at 18-h exposure. *C*, Course of competence development. Maximum competence represents 10^6 Ery-r transformants per ml per μg DNA, after a 7-min uptake period at 25 °C. Molecular weights were determined from positions of reference proteins listed in text. (Strain DP1700 is a derivative of Rx-1 carrying the *end-1 exo-2* mutations isolated in R_6 by Lacks[19], and was supplied by N. S. Shoemaker. In our hands it exhibits a tendency to lyse if handled soon after competence[11,12], seen here as low recovery of ^{35}S in sample *d* of Fig. 2. Such lysis did not occur in any of the samples of Fig. 1, as shown by complete recovery of incorporated radioactivity, and by Coumassie blue staining after electrophoresis.)

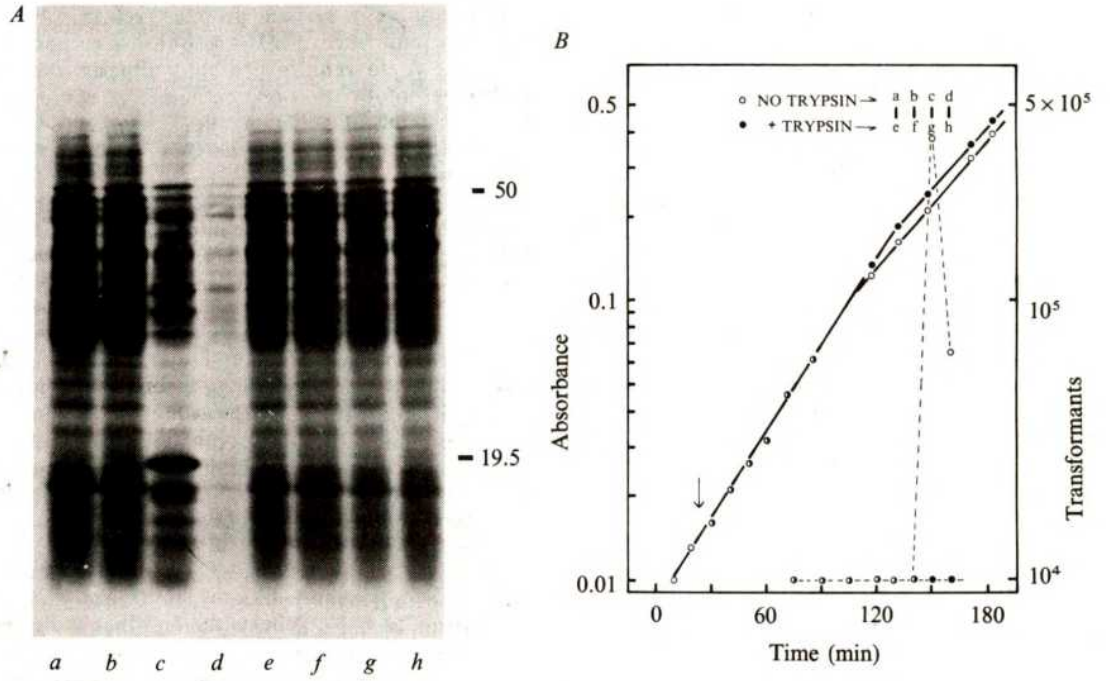

Fig. 2 Effect of trypsin on competence development and on protein synthesis patterns. A culture of DP1700 growing at 37 °C in competence medium[14] was split at the time indicated by the arrow and one half was supplemented with trypsin to 20 μg ml^{-1} (gel lanes *e–h*). The other half was an untreated control (gel lanes *a–d*). Growth was monitored at 430 nm in the Coleman jr II spectrophotometer. At intervals, samples were removed, chilled, frozen, thawed, transferred to labelling medium containing 2 μCi ml^{-1} ^{35}S-methionine, and incubated at 37 °C for 20 min. A portion of each sample was then assayed for competence, and the rest prepared for electrophoresis and analysed, as in Fig. 1. Panel *A*, fluorogram of gel for samples taken at the times indicated in panel *B*, *a–d* control, *e–h* trypsin treated. Panel *B*, culture growth and competence assays. ●, Trypsin treated; ○, control; ———, optical density of culture; - - - - - - -, competence.

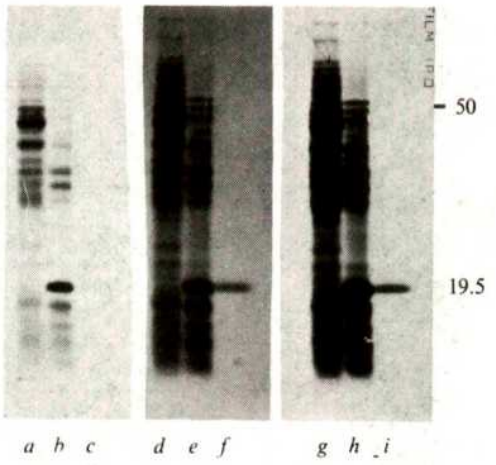

Fig. 3 Comparison of pulse-labelled proteins with purified eclipse complex protein. A lysate of component cells (*b*) labelled as in Fig. 1 (pulse *e*), was analysed on a slab gel as in Fig. 1. Adjacent lanes contained: *c*, protein obtained from ^{35}S-methionine-labelled eclipse complex purified as described elsewhere[14]; and *a*, a lysate of pulse-labelled non-competent cells. Three fluorography exposures are shown: *a–c*, 6 h; *d–f*, 12 h; and *g–i*, 18 h.

We suggest that this event, coinciding precisely with the appearance of competence, may represent the coordinated synthesis of sufficient amounts of the proteins involved in uptake and/or recombination of DNA to accomplish the rapid uptake and integration of large amounts of DNA.

Figure 3 compares the proteins labelled specifically at competence with the protein which coats donor DNA in the competent cell during eclipse, after uptake and before integration into the chromosome[14,15]. The principal competence-specific band co-migrated precisely with pure eclipse complex protein, and may consist wholly of that DNA-binding protein. By comparison with standards of BSA (MW 66,000), trypsinogen (MW 25,000), β-lactoglobulin (MW 18,400) and lysozyme (MW 14,000), we estimate the MW of this polypeptide to be $19.5 \pm 0.5 \times 10^3$, a value somewhat larger than that estimated previously[15] in an analysis heavily dependent on the mobility of cytochrome *c*.

The competence-specific 19,500 MW protein and the 19,500 MW protein of eclipse complex have not yet been directly shown to be identical; however, the correlation with competence of synthesis of the former, the binding of the latter to transforming DNA in the cell, and their identical electrophoretic mobilities strongly suggest that they will ultimately be found so.

Evidence on the nature of the competent state in any species is limited. One extreme hypothesis is that competence reflects simply the acquisition of a transport system for DNA, with constitutive proteins of nucleic acid metabolism carrying out the remaining steps. On this view, the mechanism of integration could simply represent the ordinary fate of free homologous intracellular strands of DNA. At another extreme is the hypothesis that during ordinary nucleic acid metabolism the reactions required for genetic transformation are unusual, and that competence, then, requires the coordinated synthesis of specific proteins not usually present in sufficient quantity to carry out these reactions. The elaborate shift to the synthesis of few proteins that we report here accompanies competence certainly suggests the possibility of the latter case.

Clearly, specific assignments of roles in transformation to these apparently competence-specific proteins will depend on further research involving a combination of genetic and biochemical approaches. The major competence-specific protein, p19.5, of course, is already apparently implicated by its binding to DNA in eclipse. If even a few others should also be identified, then pneumococcal competence would constitute a particularly clear example of an inducible bacterial system for genetic recombination.

Renal conservation of antifreeze peptide in Antarctic eelpout, *Rhigophila dearborni*

Joseph T. Eastman*, Arthur L. DeVries†, Robert E. Coalson‡, Robert E. Nordquist‡ & Robert B. Boyd§

In Antarctic notothenioid fishes large amounts (3% w/v) of small molecular weight glycoproteins lower the freezing point of the body fluids a few tenths of a degree below the freezing point of seawater (−1.9 °C), enabling these animals to avoid freezing[1]. Although these glycoproteins have molecular weights of 2,600–23,500 and would be expected to be filtered into the urine, they remain in the blood because the kidneys of these fishes contain only aglomerular nephrons[2,3]. Unlike the situation in most fishes, urine formation is the result of secretion rather than filtration and reabsorption. On the other hand, the peptide antifreezes in Northern Hemisphere fishes such as the winter flounder[4], *Pseudopleuronectes americanus*, are retained by the glomerular kidney even though inulin, of comparable weight, is rapidly filtered from the blood into the urine[5]. The Antarctic eelpout (zoarcid), *Rhigophila dearborni*, which is unrelated to either the Antarctic notothenioids or *P. americanus*, also uses a peptide antifreeze (molecular weight 6,000) which is maintained at a concentration of 3% (w/v) in the blood plasma. We report here that the lack of antifreeze in the urine of *R. dearborni* probably reflects the fact that the glomeruli are not functional and cannot filter. We support this conclusion with morphological and physiological evidence and relate our findings to the conservation of biological antifreeze necessary for life in ice-laden polar waters.

Rhigophila were collected in baited traps lowered to a depth of 475–550 m through the ice at McMurdo Sound, Antarctica (77° 54′ S, 166° 40′ E). The traps were retrieved 4 d later with an oceanographic winch. Fish were maintained in aquaria supplied with running water from McMurdo Sound.

Although *Rhigophila* has been reported to have glomerular kidneys[3], we could not detect any peptide antifreeze in its urine on the basis of the difference between the melting point and the freezing point. We assessed glomerular filtration rate by infusing the caudal vein with the low molecular weight polysaccharide ^{14}C-inulin which is neither secreted nor reabsorbed by the tubular epithelium. In 100 h little inulin appeared in the bladder urine. The mean ratio of ^{14}C-inulin in urine and plasma was 0.017 (5 fish), similar to values reported for the aglomerular Antarctic cods, *Dissostichus mawsoni* and *Trematomus bernacchii*[2]. During infusion, urine flow in *Rhigophila* averaged 0.285 ml h^{-1} kg^{-1} of wet weight. When ^{3}H-*p*-aminohippuric acid was infused, it appeared in the bladder urine within 1 h and maximum concentrations were observed after about 3 h when the urine/plasma ratio averaged 230. These results indicated that filtration was not involved in urine formation in *Rhigophila* even though the rate of production was similar to that of other glomerular marine teleosts.

These physiological findings led us to investigate the structure of the seemingly non-functional glomeruli of *Rhigophila*. Kidney samples were fixed for histology and electron microscopy by conventional techniques. Most Nephrons were aglomerular, and *Rhigophila* should be considered a pauciglomerular fish. The glomeruli were small compared to tubule diameter. Although some glomeruli had a few patent capillary loops, most exhibited no vascularity. Nephrons with glomeruli had short neck segments. The only other recognisable regions of the nephron were the second proximal (principal) segment and the collecting tubule, resembling the situation in truly aglomerular fishes[6].

The squamous epithelium of the parietal layer of Bowman's capsule continued without change into the very short neck portion of the nephron. Although the lumina of Bowman's space and the neck were easily seen, it was difficult to demonstrate a direct connection between the lumina of the neck and the rest of the nephron. Serial section reconstruction verified that the epithelial components of the two portions were continuous, but continuity of the lumina could not be established. If significant amounts of glomerular filtrate were produced, the passage of filtrate into the neck would be expected to keep the lumen visible. The paucity of vascular loops within the glomerulus and the failure to demonstrate luminal patency in a portion of the nephron suggested that there was little or no filtration.

As a further test of glomerular vessel patency, Microfil (Canton Bio-Medical Products) was gravity perfused through the ventral aorta after blood had been washed out with heparinised marine teleost Ringer solution. Small arterial vessels on the capsule and in the interior of the kidney were filled, but we found no evidence of the Microfil in glomerular capillaries. We concluded that the blood supply to the kidney of *Rhigophila* was predominantly venous, as in aglomerular fishes[6].

Ultrastructural studies confirmed that the glomeruli of *Rhigophila* were not functional. The endothelium of the glomerular capillaries was thick and lacked fenestrae (Fig. 1). The basement membranes were also thick (Fig. 1), presumably from the deposition of material produced by the mesangial cells. The cells of the visceral layer of Bowman's capsule lacked the characteristic podocyte appearance including pedicles and filtration slits (Fig. 1). These features resemble the glomerular characteristics associated with certain mammalian kidney diseases[6,7]. We do not interpret the glomerular morphology of *Rhigophila* as pathological, but rather as a consequence of degeneration during evolution. A similar situation occurs during the regression of the larval opisthonephros in the sea lamprey, *Petromyzon marinus*[7].

Ultrastructural features of the cells forming the principal part of the nephron included a brush border with occasional cilia, apical tubules and vesicles, numerous junctional complexes and smooth muscle cells around the tubule. There were very few lysosomes in the apical cytoplasm of the tubule cells. These organelles are normally present in tubule cells active in filtrate reabsorption[6]. Their scarcity was another indication of reduced glomerular filtration in *Rhigophila*.

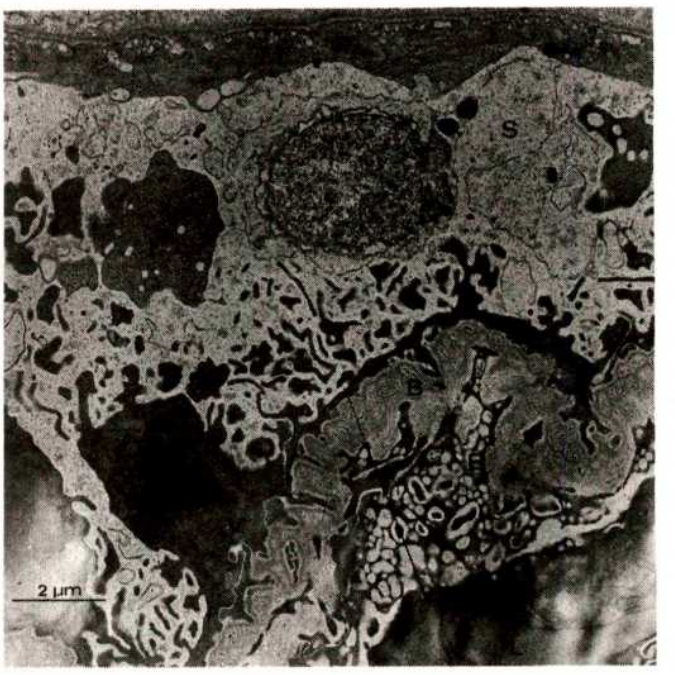

Fig. 1 Electron micrograph of a renal corpuscle from *Rhigophila*. P, parietal layer of Bowman's capsule; V, visceral layer (podocytes) of Bowman's capsule; S, Bowman's space; B, basement membrane; E, endothelium and L, lumen of glomerular capillary. The glomerular endothelium lacks fenestrations and the podocytes lack pedicles and filtration slits. Double-headed arrow indicates the thickness of the filtration barrier (about 5.0 μm).

Rhigophila antifreeze peptide molecules are negatively charged (isoelectric point 5.5–6.0). Research on mammalian kidneys has shown that the passage of negatively charged molecules through the filtration barrier is restricted by carboxyl-rich glycoproteins in the subendothelial and subepithelial layers of the glomerular basement membrane[8–11]. Although this mechanism may not be important in the thick glomerular walls of *Rhigophila*, it may be operational in the related north Atlantic eelpout, *Macrozoarces americanus*, and in *P. americanus*. These species filter inulin freely and also possess acidic peptides with antifreeze properties during the winter (A.L.D., unpublished data).

The reduction or loss of glomerular surface area in marine teleosts has been viewed as an energy conserving mechanism[6]. By reducing the number of small organic solutes and neutral macromolecules escaping from the plasma at the glomerulus, energy need not be expended in reabsorbing these 'useful' components from the filtrate[6]. The pauci- and aglomerular kidneys of many polar fishes have the additional advantage of preventing or minimising urinary loss of small peptides and glycoproteins with antifreeze properties[2]. Energy conservation is likely to have been especially important in the adaptation of polar fishes to their environment, and the unusual kidneys of *Rhigophila* are an intriguing manifestation of this adaptation.

APPOINTMENTS VACANT

UNIVERSITY OF THE WITWATERSRAND
Johannesburg
DEPARTMENT OF ANATOMY
SENIOR LECTURERS/ LECTURERS

Applications are invited from suitably qualified persons, regardless of sex, race, colour or national origin, for appointment to the above two posts, which are available from January 1980. One of these posts is a contract appointment for one year in the first instance. Candidates should have an interest in one or more of the following branches of Anatomy: Human Gross Anatomy, Neuro-anatomy, Comparative Morphology and any of the subdivisions of Human Biology.

The salary attached to these posts is within the following ranges: Senior Lecturer: R15 000 — R19 500 per annum. Lecturer: R8 100 — R16 800 per annum (£1 = R1.77 approx).

Applicants not meeting the required standard of qualifications and/or experience may be offered appointment at a lower level.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and to the above posts are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged by 30th November 1979. 3704(A)

STANFORD UNIVERSITY
GEOCHEMIST —PETROLOGIST

The Department of Geology in the School of Earth Sciences invites applications for a faculty position beginning September, 1980. Areas of interest include (but are not limited to) geochemical processes in the crust and mantle of the earth including isotope geochemistry, thermodynamics, kinetics, element distribution and phase equilibria studies. Teaching responsibilities might include graduate and undergraduate courses in geochemistry and igneous petrology. Level of appointment is open, but we are particularly interested in a creative young person, with a well-established record in research.

Applications should include (1) a resume of education, professional experience, and published research; (2) a brief statement of plans for future research, and (3) the names of 4 referees. Send to: Prof. J.G. Liou, Department of Geology, Stanford University, Stanford, CA 94305, by December 1st, 1979. Stanford University is an equal-opportunity/affirmative-action employer. W329(A)

METAMORPHIC PETROLOGIST
DEPARTMENT OF GEOLOGICAL SCIENCES
THE UNIVERSITY OF TEXAS AT AUSTIN

A tenure-track faculty position is now open in metamorphic petrology, effective September 1980. The candidates must be field oriented and able to use modern laboratory instruments for research and teaching. An interest in mineral resources is desirable. Teaching responsibilities will include graduate and undergraduate metamorphic petrology, undergraduate mineralogy and field instruction, and supervision of graduate research.

Applicants for this position must have completed all requirements for the Ph.D. degree at the time of employment. Please send complete résumé, including names of three references, an abstract of the dissertation, statement of research interests and planned research projects to: Dr Robert E Boyer, Chairman, Department of Geological Sciences, The University of Texas at Austin, P.O. Box 7909, Austin, Texas 78712.

Deadline for applications: January 15, 1980. Equal Opportunity/Affirmative Action Employer, M/F. W519(A)

ATHROFA GOGLEDD-DD CYMRU
The North East Wales Institute of Higher Education
SCHOOL OF NATURAL SCIENCE (RESEARCH DIVISION)
Kelsterton College
RESEARCH ASSISTANTS

Two posts are available, initially for a 2 year period, for a suitably qualified:
1. Biochemist, with interests in cellular and intermediary metabolism.
2. Cell biologist, preferably with experience in tissue culture techniques.

Both posts are industrially-sponsored, and form part of the Institute's programme of drug research, under the general supervision of Dr J C Allen, the Head of the Research Division. The Division possesses well equipped animal and tissue culture facilities.

Appointment will be on the T3/4 Grade of the NJC scales, with salary between £4,080 and £5,067 pa. Applicants, who should be Honours Graduates, and who will have the opportunity to register for a higher degree, should apply to The Institute Registrar, Kelsterton College, Connah's Quay, Clwyd, before 30th November, 1979. 3695(A)

CELL BIOLOGIST
(Associate Professor)

Applications are solicited for a nine-month tenure track faculty position in cell biology. All qualified cell biologists (animal and plant) without regard to specialty are encouraged to apply. The appointment will be at the Associate Professor level and will be available Autumn, 1980. Applicants must have demonstrated excellence in research and teaching. Responsibilities of the successful candidate will include developing and directing a quality research program in some aspect of cell biology, advising graduate students, development and teaching of a graduate level course in his or her specialty in cell biology, and teaching general cell biology to undergraduate students. A complete curriculum vitae and a list of three references should be sent to Professor Joseph Y. Cassim, Chairman, Cell Biology Search Committee, Department of Microbiology, The Ohio State University, 484 W 12th Avenue, Columbus, Ohio 43210. Applications will be accepted until January 15, 1980.

An Equal Opportunity/Affirmative Action Employer. Qualified women, minority and handicapped persons, as well as others are encouraged to apply. W514(A)

Laser Scientist

The Rutherford Laboratory is one of the Science Research Council's principal establishments for advanced work in physics and is also one of Europe's leading centres for laser research.

The Laser Division has a vacancy for a Research Associate to work in an existing program of gas laser development. The present emphasis in this work is on the development of efficient, high power rare-gas halide lasers excited by fast electric discharges of high voltage electron beams. These lasers are of interest for use in laser-plasma interaction studies. A Ph.D in physics or a related area is required and previous experience in lasers or gas discharge physics would be an advantage.

The post is tenable for 3 years on the salary scale £5,273-£7,086 (with a further pay rise on 1.1.80).

Benefits include a Non-contributory Superannuation Scheme and generous sick leave and annual leave allowances.

Write or telephone for an application form to:

Jane Griffiths in the Personnel Group quoting ref: VN 858. Rutherford and Appleton Laboratories, Chilton, Didcot, Oxon OX11 0QX. Tel: Abingdon (0235) 21900 ext. 510.

The closing date for applications is 30th November, 1979.

3659(A)

Petroleum Geochemist

Worldwide Exploration Activities

We need a Geochemist, to work in our Geochemical Review Group, who has several years' experience of the application of geochemical techniques to exploration problems in the oil industry.

Part of our Exploration Division, this Group is concerned with the integration of geochemical and geological data into a regional framework presently covering the U.K., Ireland, the Middle East, Malaysia and North America. Some travel to these areas may be required.

Applicants should be aged 25 to 35 years with a good Honours Degree in Geology and a PhD in Organic Geochemistry.

Vacancies also exist within our Geochemical Branch for applicants similarly qualified but with less experience.

Starting salaries will be dependent on age and experience, with excellent benefits including non-contributory pension scheme, four weeks' holiday and relocation assistance, where appropriate.

Please write with full details of qualifications and experience to:

Mrs. L. Fuller, BP Research Centre, Chertsey Road, Sunbury-on-Thames, Middlesex TW16 7LN.

BP Research Centre Sunbury on Thames BP

3667(A)

The University of New England Armidale — Australia

Professor of Botany

The University invites applications for the Chair in Botany. The appointee will be Head of the Department for five years in the first instance.

The Department offers courses for internal students in the Faculties of Science, Resource Management, and Rural Science, and for internal and external students in the Faculty of Arts.

Full particulars can be obtained from the Staff Officer, University of New England, Armidale, New South Wales, 2351, Australia, with whom applications, which should include the names and addresses of three referees, close on 31st December, 1979, stating position No. 442.

Informal enquiries may be directed in the first instance to the Dean, Faculty of Science. 3657(A)

UNIVERSITY OF THE WITWATERSRAND
Johannesburg
South Africa

DEPARTMENT OF APPLIED MATHEMATICS

This Department consists of three divisions: Applied Mathematics, Computer Science and Statistics. It has active groups in various areas of Applied Mathematics, Computer Science and Operations Research.

Applications are invited from suitably qualified persons for appointment to the following posts:

(1) *Chair of Statistics*
The successful applicant will be Head of the Division of Statistics and will be expected to lead the Division in its teaching and research efforts. The applicant's own field of interest may be in Mathematical Statistics, Applied Statistics or Operations Research.

(2) *Chair of Computer Science*
The successful applicant will be Head of the Division of Computer Science and will be expected to lead the Division in its teaching and research efforts.

(3) *Chair in the Field of Mathematics*
This Chair falls within the Department of Applied Mathematics and applications will be considered from academically well qualified candidates who have active research interests in any of the Mathematical Sciences.

Salary attached to these posts will be within the range R15 000 — R18 000 per annum. A limited amount of private work will be allowed. (£1 = R1.77 approx).

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice and to the above posts are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged by 30 November 1979. Applicants should indicate the post for which they are applying. 3705(A)

PLYMOUTH POLYTECHNIC

School of Enviromental Sciences
RESEARCH ASSISTANT MICROBIOLOGY

To work on the isolation and characterisation of Toxins from fish pathogenic bacteria.

Applicants should hold a degree in Microbiology Biochemistry or related subject and will be expected to register for a higher degree. The post would also be suitable for a post-doctoral candidate.

Research assistant are normally required to register for a higher degree, although post doctoral applicants will be considered. Appointments are for a period of two years with a possibility of a third year (fixed term contracts).

Salary will be £3480 for postgraduates or £3780 post-doctoral (or equivalent) with annual increments of £150.

Application forms returnable by 30th November 1979 and further particulars can be obtained from the Personnel Officer, Plymouth Polytechnic, Drake Circus, Plymouth PL4 8AA.

3719(A)

NATIONAL UNIVERSITY OF LESOTHO

Applications are invited for the

CHAIR OF BIOLOGY

tenable from January 1980. Candidates should have a higher degree and at least 10 years university teaching, research and administrative experience. Candidates working in any area of biology, applicable to a montane, grassland environment may apply but it is unlikely that an appointment will be made in the fields of genetics, entomology, biochemistry or plant physiology which are already covered by present members of staff. Preference will be given to candidates whose teaching and research experience is in ecology. Those who responded to the previous advertisement need not reapply, their applications will be considered alongside new ones. The appointment will be on permanent terms for local applicants or on contract terms for limited periods of two to four years for expatriate applicants in the first instance.

Salary: R8580 — R8790 — R9000 pa (£1 sterling = R1.78). The British Government may supplement salary by £3870 pa (sterling) for married appointee or £2766 pa (sterling) for single appointee (presently under review and normally free from tax) and provide childrens education allowances and holiday visit passages. Family passages; baggage allowance; superannuation is non-contributory for appointees on permanent Terms of Service, while appointees on short contract terms receive 25% gratuity in lieu of superannuation for the first two years of the contract rising to 27½% and 30% for each subsequent and similar period of service; 15% inducement allowance for those not qualifying for any supplementation scheme, unless married to another supplemented member of staff; subsidised accommodation is available; education allowance for expatriates; overseas leave every 2 years; study leave every four years.

Detailed applications (2 copies) with curriculum vitae and naming three referees should be sent by 10th December, 1979 to the Assistant Registrar (Appointments), NUL, Roma, Lesotho, Africa. Applicants resident in the UK should also send one copy to the Inter-University Council, 90/91 Tottenham Court Road, London W1P ODT. Further particulars may be obtained from either address. 3685(A)

IRAM
Institut de Radio Astronomie Millimétrique

requires a

PHYSICIST/RADIO ASTRONOMER

with broad background and experience in the use and/or development of radio interferometers, to participate in several of the following activities:

The design and development of surface measurements of high precision antennas by holographic and/or interferometry methods.

The design and development of focal systems for multifrequency observations, polarization measurements, with consideration of problems of standing waves and "Baseline ripple".

The analysis of the possible use of various physical devices such as fast logical circuits, quasi-optical components, acousto-optical systems, fibre optics.

The development of observing and data reduction methods for radio astronomical interferometers with little known or unknown phase.

The station of work will be GRENOBLE.

Minimum base salary is about: 7500 F.F./month.

Applicants should send curriculum vitae with a list of publications and the names of a few references to: Institut de Radio Astronomie Millimétrique, 53 Avenue des Martyrs, 38026 Grenoble CEDEX, France. W507(A)

CSIRO AUSTRALIA

Chief of Division Division of Manufacturing Technology

Applications are invited from scientists and engineers, who have an established record of personal research achievement and leadership, for the position of Foundation Chief of the newly formed Division of Manufacturing Technology. The new Division has been established by separating from the Division of Materials Science its staff and resources engaged in the research detailed below.

CSIRO is Australia's largest and most comprehensive research organisation having approximately 7,000 employees of whom 2,400 are research and professional scientists. Its broad charter covers research into problems of primary and secondary industries and such fields of community interest as human nutrition, the environment and the development and use of natural resources. The organisation's 43 scientific research divisions and units, which are dispersed throughout Australia, have recently been grouped into 5 institutes. Each institute is headed by a Director. The Division of Manufacturing Technology is one of the divisions within the Institute of Industrial Technology. Other component divisions of the Institute are the Divisions of Applied Organic Chemistry, Building Research, Chemical Technology, Mechanical Engineering, Protein Chemistry, Textile Industry and Textile Physics.

The Division of Manufacturing Technology has laboratories in Melbourne and Adelaide and the future establishment of laboratories in Sydney is envisaged. The divisional headquarters will be located in either Melbourne or Adelaide. The Executive will determine the location in consultation with the Chief-Designate. The current staff of the Division is 67 of whom 34 are professional scientists. The objectives of the Division are to develop new and improved fabrication methods, to maximise the economic use of materials and to improve their properties having regard to the technology of their use. There is particular emphasis on the improved processing and utilisation of indigenous raw materials.

The present programs aim at providing the technological base for continuing economic viability in areas of metal fabrication which are fundamental to a wide range of industrial activities. The programs are carried out in conjunction with industry groups to ensure maximum external input and ease of implementation. The inter-disciplinary approach emphasises technological advancement through the development of the basic principles of physics, metallurgy and engineering. The present programs encompass a range of high volume, high precision forming processes from both liquid and solid metal, the wear and corrosion of components and their prevention by a variety of surface treatments. It is intended that the divisional programs will be expanded to include a wider range of materials and manufacturing activities.

In appointing a Foundation Chief, the CSIRO Executive wishes to establish the Division of Manufacturing Technology as a prime centre of expertise for the Australian manufacturing industry. This will require the Chief to have proven ability in identifying long-term industrial problems, and in technology transfer and implementation as well as research leadership.

A Chief of Division is responsible for the development, scientific direction and integration of the research programs of the Division and for the development of active collaboration with industry bodies and research associations. The Chief of the Division of Manufacturing Technology will be expected to have a close working knowledge of the manufacturing industry in Australia and its research and development requirements.

The salary for the position is negotiable but will not be less than Dols Aust 35,474 p.a.

The terms of the appointment will be discussed with the short-listed applicants at the inverview. The appointee would be eligible to contribute to the Commonwealth Superannuation Scheme.

Further information on the Division is in a booklet available on request from the Secretary, CSIRO, at the address below.

Dr H.W. Worner, Director of the Institute of Industrial Technology and Chairman of the Appointment Committee, who may be contacted at the address below, will be available for discussions concerning the appointment with applicants and other interested parties.

Applications stating full personal and professional details and names of at least two professional referees and quoting reference number 1600/001 should reach The Secretary, CSIRO, PO Box 225, Dickson, A.C.T. 2602, Australia by 14 December, 1979.

3714(A)

CSIRO AUSTRALIA

Postdoctoral Research Fellow

Division of Applied Physics Sydney

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7000 employees — 2400 of who are research and professional scientists — located in Divisions and Sections throughout Australia.

Field: Non-Destructive Testing

General: The Division has the role of maintaining and developing Australian standards of measurement of physical quantities. It undertakes problems of research in related areas, and is involved in the solution of specific problems relating to industry. The Division is located in a large new laboratory complex at West Lindfield. In addition there are branch laboratories in Adelaide and Melbourne.

Duties: To assume a major role in the establishment of a new research activity in the field of non-destructive testing as part of the Division's programme of assistance for Australian manufacturing industry. Emphasis will be placed on using ultrasonic techniques to extend the present sensitivity limits for the detection of defects and to improve the precision with which defects can be characterized. The project will have a close relationship with existing research activities, including studies in vibration, acoustics, solid state physics and optical holography.

Qualifications: A PhD in Physics or Engineering, or equivalent qualifications, with experience in ultrasonics. Some knowledge of appropriate areas of metallurgy would be an advantage.

Salary: Research Scientist/Senior Research Scientist: $A15,916 — $A23,122 pa.

Tenure: A fixed term appointment of three to five years may be negotiated. Commonwealth Superannuation is available.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 750/781 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 7th December 1979.

Applications in U.S.A. and Canada should be sent to: — The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 3687(A)

Directorate of Scientific Services

Assistant Microbiologist

Max Salary £6,900 p.a.

To work at the New River Head Laboratories, Rosebery Avenue, EC1.

Will be required to undertake microbiological examination of water at all stages of treatment, research and development work.

Applicants should hold a degree in a natural science and have considerable experience in the microbiological analysis of water for public supply.

Application forms available from the Assistant Director (Personnel — Staff), New River Head, Rosebery Avenue, London EC1R 4TP or telephone 01-837 3300 Ext. 2024. 3672(A)

Thames Water

THE QUEEN'S UNIVERSITY OF BELFAST

LECTURESHIP IN BIOCHEMISTRY

A lectureship in the Department of Biochemistry is available from 1st January, 1980, or such other date as may be arranged. The lecturer will be expected to teach at various levels and to engage in research, preferably collaborative, in fields already active in the Department, details of which are set out in a departmental prospectus which is available. Initial placing, which will depend on age, experience and qualifications, will be made at one of the first three points on the scale for lecturers; £4335, £4623, £4911 rising to £8994 with contributory pension rights under the FSSU/USS. The appointment will be subject to a period of probation of up to three years.

Further particulars are available from the Personnel Officer, The Queen's University of Belfast, Belfast BT7 1NN, Northern Ireland. Closing date: 23rd November 1979. (Please quote Ref: 79/N). 3671(A)

POSITIONS ARE AVAILABLE in the Department of Biochemistry for teacher-researchers in molecular genetics and in the metabolism and structure of cell surface glycoproteins or the components of the cytoskeletal system. The positions are tenure track and are at the level of assistant professor. Interested candidates should contact: Dr M Waite, Department of Biochemistry, Bowman Gray School of Medicine of Wake Forest University, Winston-Salam, North Carolina 27103. Telephone (919) 727 4255. An Equal Employment Opportunity/Affirmative Action Employer. W515(A)

GRIFFITH UNIVERSITY
Australia

SCIENCE, TECHNOLOGY AND SOCIETY

READER/SENIOR LECTURER
(re-advertisement)

Applications are invited from qualified men and women for the senior academic appointment in the area of Science, Technology and Society (STS) within the School of Science. The appointee will have had extensive training and research experience in one or more aspects of science policy. Applications from persons with interests in Technological and Social Change and/or Science and Government in either the developed or developing worlds would be particularly welcome.

Undergraduate students in the School are required to study STS for a quarter of their time in first year and optional courses are available in later years. A coursework M.Sc. programme has taken its third cohort of students. The appointee will have considerable responsibilities in the teaching programmes and in the academic development of STS within the School.

A Science Policy Research Centre (SPRC) has been established and the appointee will assume the position of Director of the SPRC, and as a consequence will have a reduced teaching load. Funds for a part-time research assistant are provided initially.

Salary Scales: Reader — $A28,809; Senior Lecturer — $A21,858-$25,477. The University also meets the cost of reasonable removal expenses.

Further details and the method of application are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF. Applications close on *30 November 1979.* 3670(A)

TECHNICIAN/ RESEARCH OFFICER

to assist our Hormone Biochemistry Laboratory in the use of biochemical and cell culture techniques to investigate the action of steroid hormones in regulating the growth of breast tumour cells.

HNC/Degree. Salary range £4122 to £5949. For further information and application form write or telephone Miss S M Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 on 242-0200 ext 305, quoting reference HB1. 3674(A)

IMPERIAL COLLEGE OF SCIENCE
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH FELLOW

Applications invited for a post-doctoral research assistantship to work on the magnetic properties of metal porphyrins in solution. The post is for two years, starting as soon as possible. Salary on Scale £4333 — £7521 plus £740 London Allowance.

Applications enclosing a curriculum vitae and the names of two referees should be sent to Dr D.F. Evans, Department of Chemistry, Imperial College of Science, London SW7. 3718(P)

UNIVERSITY OF REGINA
DEPARTMENT OF BIOLOGY AND CHEMISTRY
POSTDOCTORAL POSITIONS

A two year postdoctoral position (salary approx. $14,500) is available in a molecular biology-biochemistry laboratory (headed by Dr H. Bertrand) studying the genetic control of the biogenesis of mitochondria respiratory complexes in *Neurospora crassa*. The laboratory is well equipped for research on the assembly and function of submitochondrial complexes, restriction mapping of DNA, protein and nucleic acid chemistry and for genetic manipulations.

A second postdoctoral position ($1,000 Cdn/month; ending June 30, 1979 with the possibility of an additional year pending budgetary approval) is available for research on the regulation of pyrimidine and arginine metabolism in *Salmonella typhimurium* (headed by Dr R.A. Kelln). Research activities will include mutant isolation, genetic mapping, nucleotide pool quantitation enzyme assays and protein and nucleic acid chemistry.

Interested individuals should be available as soon as possible and should have completed a PhD degree in biochemistry, genetics or physiology.

Applications, in the form of curriculum vitae with names and addresses of three references should be sent to:

Department of Biology (or Chemistry) University of Regina, Regina Saskatchewan, Canada S4S 0A2. W487(A)

RESEARCH SCIENTIST
Corrosion Science
Electrochemistry
Metallurgy
Physics

This senior position in the FONTANA CORROSION CENTER will be of interest to persons who hold a PhD degree in metallurgy, physics, physical chemistry, or corrosion science, and who have an established record of scientific research. The successful applicant will direct research on a wide variety of fundamental and applied problems.

Interested persons should send résumés and the names of three referees to Prof. D D Macdonald, Director.

Fontana Corrosion Center, Dept. of Metallurgical Engineering, The Ohio State University, 116 West 19th Avenue, Columbus, Ohio 43210, USA.

An equal opportunity/affirmative action employer. W513(A)

THE AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF CHEMISTRY

CHAIRS OF ORGANIC CHEMISTRY

Applications are invited for appointment as Professor of Chemistry with special reference to Organic Chemistry, following the retirement on 31 December 1980 of Professor A J Birch, FAA, FRS. A second chair has recently been established and may be filled at the same time.

Founded in 1967, the Research School of Chemistry is an integrated School without departments. A professor who is not Head of School can devote almost his whole effort to research, being expected only to attend to minor administration in the subject area as a whole and to play some part in University affairs. However, a professor is expected, if invited by the Council, to serve a three-year term as Head of School at some stage. The Dean as Head of School is chosen by the Council from amongst the professors in the School. The Dean acts with the advice of the Faculty and the Faculty Board, but has the executive power to act on his own behalf. The present Dean is Professor D P Craig, FAA, FRS.

The School has a total academic staff of seventy-four, of whom fourteen hold tenured appointments. There are four professors (Professors A J Birch, D P Craig, B G Hyde and A M Sargeson) and three professorial fellows (Dr M A Bennett, Dr J Ferguson and Mr R W Rickards). The School has no responsibility for undergraduate teaching. It carries out research and teaches graduate students, is well equipped by modern standards, and is well supported by technical and administrative staff.

In the Organic area there are five tenured staff members leading independent research groups (Professor A J Birch, Mr R W Rickards, Dr J K MacLeod, Dr L N Mander and Dr L Radom); there are at present twenty-two research fellows and eight PhD students.

The normal salary level is $A36,253 per annum. Current exchange rates $A1:50p: $US1.13. Superannuation benefits are available. The University meets reasonable travel and removal expenses for the appointee and family and also assists in providing suitable housing.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Further information about the position may be obtained from the Registrar, P.O. Box 4, Canberra, ACT 2600, Australia, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications close on *11 January 1980.* 3660(A)

U M I S T

POST-DOCTORAL RESEARCH IN CORROSION

Aplications are invited from suitably qualified scientists to undertake research in a number of areas, including:

(a) The effect of ion implantation on the corrosion, oxidation, wear and other surface properties of copper.
(b) The mechanisms of the inhibition of the corrosion of aluminium.
(c) The etching of aluminium.

Prior experience in the field of corrosion is desirable, but not essential. Salary will be on the scale £4333 — £7521 per annum.

Enquiries for further information should be addressed to Professor G C Wood, Corrosion and Protection Centre, UMIST.

Requests for application forms, quoting reference CPC/229, should be addressed to the Registrar, UMIST, P.O. Box 88, Manchester M60 1QD. The closing date for this post is 22 November 1979. 3664(A)

RE-ADVERTISEMENT
MEDICAL RESEARCH COUNCIL

VIROLOGY UNIT

ENZYMOLOGIST
PROTEIN BIOCHEMIST
and
NUCLEIC ACID BIOCHEMIST

Two vacancies exist for post-doctoral research scientists with experience in enzymology/protein biochemistry or nucleic acid biochemistry to work on a variety of molecular biological problems involving Herpes Simplex Virus and other mammalian virus systems.

Previous experience with virus systems is advantageous but not esential.

Each appointment will be for three years. Salary on an appropriate point on Grade 2 of the non-clinical scientific staff scale (£4,333 to £6,932). Applicants should send a Curriculum vitae giving full details of qualifications and experience and the names and addresses of three professional referees to: Professor J.H. Subak-Sharpe, Institute of Virology, University of Glasgow, Church Street, Glasgow, G11 5JR by 15th December, 1979. 3712(A)

AGRICULTURAL RESEARCH COUNCIL

INSTITUTE OF ANIMAL PHYSIOLOGY
Babraham, Cambridge
CB2 4AT

A vacancy, financed by the M.R.C. for 3 years, exists for a Biochemist to conduct research into the structure of Major Transplantation Antigens in relation to their biological properties. Salary in Scientific Officer (£3,289 — £5,085 at present. £3,591 — £5,486 from 1.1.80 p.a.) or Higher Scientific Officer (£4,727 — £6,211 at present. £5,097 — £6,737 from 1.1.80 p.a.) scale according to experience.

Qualifications for S.O.: Degree in an appropriate subject or H.N.C. with relevant experience; at least five years relevant post qualifying experience required for H.S.O. (preference for Ph.D.). Non-contributory superannuation scheme.

Applications quoting reference J.C.H.4. to the Secretary of the Institute by 23rd November 1979. 3707(A)

SANDOZ

Pathology

Sandoz Limited is a major Swiss-based multinational pharmaceutical company with a large, modern and well equipped Toxicology Institute in Basle, Switzerland. We are looking for suitable candidates to fill 2 posts that have recently become vacant in our Pathology Department.

A. Head of Section

Job Description: Overall responsibility for the activities of the Pathology Section which comprises a staff of about 20 members including 4 pathologists (Medical Doctors and Veterinarians). The routine activities of the section include the planning, supervision, evaluation and reporting of the post mortem aspects of chronic toxicity studies conducted on animals, including carcinogenicity tests. Since academic members of the Department are also encouraged to pursue their own research interest and to investigate the mechanisms by which drugs induce their toxicity, the Section Head is also expected to be in a position to contribute and encourage such activities. There will be ample opportunities to attend scientific conferences. The Head of Pathology is directly responsible to the Head of Toxicology.

The Ideal Candidate: Will be 30-45 years of age, possess a medical or veterinary qualification (preferably with a higher degree in Pathology) and will have considerable practical experience of laboratory animal pathology. Administrative ability is required for this position as is excellent written and spoken English. Previous industrial experience and a knowledge of German would be advantageous.

B. Pathologist

Job Description: The planning, supervision, evaluation and reporting of the post mortem aspects of chronic toxicity studies conducted on animals (especially carcinogenicity tests on rats and mice). In addition, the investigation of the mechanism by which drugs induce their toxicity. There will be ample opportunities to pursue individual scientific interests, to attend scientific conferences and for the periodic updating of expertise through stays in external laboratories (universities, etc). The pathologist will have 2 histology laboratories and attendant staff (5 technicians) at his disposal. He will be directly responsible to the Head of Pathology.

The Ideal Candidate: Will be 30-45 years of age and have a degree in Medicine, Veterinary Medicine or an appropriate biological discipline. In addition, he will have experience of laboratory animal pathology, preferably with specialized knowledge of tumor pathology and its diagnosis. Organizational talent is required for this post and previous industrial experience and some knowledge of German would be advantageous.

General Information:

- Removal expenses to Switzerland will be defrayed by Sandoz Ltd.
- The firm runs a contributory pension scheme.
- The Toxicology Institute is located in pleasant rural surroundings some 6 miles from the centre of Basle.

Interviews of suitable candidates for both posts will be held in London in mid-November. Short list candidates will be subsequently invited to Basle.

Applications, which should be made in writing, should be accompanied by a comprehensive curriculum vitae and the names of two referees.

Apply to: The Personnel Department, Ref. 1244, Sandoz Ltd., CH-4002 Basle, Switzerland.

W458(A)

Boehringer Mannheim GmbH is a pharmaceutical company strongly engagend also in the field of biochemical research reagents.
Applications are invited for the position of

BIOCHEMIST

in our R&D laboratories in Tutzing/South of Munic. This position in the Molecular Biology department offers a opportunity to join a young and enthusiastic team involved in the challenging developmental research towards the production of enzymes acting on nucleic acids.

The successful candidate will already have practical skills and experience in analytics, application and/or isolation of these enzymes. Knowledge of the German language is required.

The firm offers excellent conditions of employment.

For further information please send your application with scientific curriculum vitae to

BOEHRINGER MANNHEIM GMBH
Biochemica Werk Tutzing

W512(A)

UNIVERSITY COLLEGE DUBLIN

Applications are invited by the Governing Body of the College for the following full-time statutory appointment:

PROFESSORSHIP OF GEOLOGY

Prior to application, further information (including application procedure) should be obtained from the Secretary and Bursar, University College, Belfield, Dublin 4. Telephone enquiries: 693244, ext. 431.

The closing date for receipt of completed applications is Thursday, 6th December, 1979. 3623(A)

IMPERIAL COLLEGE (University of London)

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANT

to work with Dr Bruton on the structure and interactions of aminoacyl-TRNA synthesis. Experience in protein or nucleic acid chemistry is highly desirable. Salary in the range £5,073 to £8,261 (inc). The post is funded by the SRC and is for 2 and three quarter years.

Applications, including a full c.v. and the names and addresses of two academic referees should be sent to Dr Chris Bruton, Department of Biochemistry, Imperial College, London SW7 2AZ. 3683(A)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited from neurobiologists with previous research experience in Neurophysiology/Pharmacology for a post to study the effects of long-term antidepressant drug administration on monoamine release and receptor activity in rat brain using *in vitro* techniques. The appointment is for three years commencing as soon as possible. Initial salary £4,333.

Applicants should send their curriculum vitae and names of two referees to Dr C. A. Marsden, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH from whom further information may be obtained (0602) 700111 Ext. 3297. 3679(A)

UNIVERSITY OF LONDON

INSTITUTE OF NEUROLOGY

Applications are invited for a post-doctoral position in a Research Group supported by an MRC programme grant working on neurochemical and behavioural effects of environment, nutrition and experimental disease (liver, kidney failure, etc). Salary between £5,073 — £8,261 (incl. London Weighting).

Curriculum vitae with names of 2 referees by 7 December to Professor G. Curzon, Institute of Neurology Labs, 33 John's Mews, London, WC1. 3706(A)

UNIVERSITY OF MANCHESTER

RESEARCH ASSOCIATE in MEDICAL BIOCHEMISTRY

Applications are invited from post-doctoral candidates for this post (available for three years) to work on glycoproteins and proteoglycans in collagenous structures of blood vessels. Some experience in the fields of connective tissue glycoconjugates, immunolocalisation or cell culture would be an advantage. Starting salary in the range £4,333 — £4,910 p.a.

Applications with full curriculum vitae and the names of two referees should be sent, as soon as possible, to Professor D S Jackson, Department of Medical Biochemistry, University of Manchester Medical School, Manchester M13 9PT. 3709(A)

ROYAL HOSPITAL FOR SICK CHILDREN

DEPARTMENT OF PATHOLOGY

RESEARCH ASSISTANT

Graduate Biochemist required for work on the expression of enzyme markers in malignant disease. Opportunity for undertaking higher degree. Salary according to nationally agreed scales.

Applications giving the names of two referees should be sent as soon as possible to The Secretary, Department of Pathology, Royal Hospital for Sick Children, Edinburgh, EH9 1LF. Tel: 031 667 1991 ext 270. 3713(A)

KING'S COLLEGE LONDON

TECHNICIAN GRADE 4

To be in charge of the day-to-day running of practical classes for medical, dental and B.Sc. students in the Anatomy Department. There are new Faculty Laboratories serviced by a Departmental Preparation Room. O.N.C. or equivalent qualification required with a minimum of 7 years experience including histology.

The successful applicant will be responsible for the expansion of histology teaching material. Salary on scale £4212 p.a. rising to £4730 p.a. inclusive (under review). 5 weeks annual holiday. Superannuation scheme. Interest-free loans for annual rail reason tickets. Apply in writing with full details to: The Head Clerk (Ref: 221734N), King's College London, Strand, WC2R 2LS. 3703(A)

AGRICULTURAL RESEARCH COUNCIL

FOOD RESEARCH INSTITUTE

Chemistry and biochemistry Division (Physical Methods Group)

PHYSICIST/PHYSICAL CHEMIST (Scientific Officer)

A Physicist/Physical Chemist is required to join a newly-constituted team to study the physicochemical properties of dispersions and gels in foods.

Qualifications: First or Upper Second Class Honours degree in Physics, Chemistry or biochemistry. Previous experience in surface chemistry or in the use of physical methods in Biology will be an advantage.

Salary: From 1st August 1979: on a scale £3,289 — £5,085. From 1st January 1980: on a scale £3,591 — £5,486.

Non-contributory superannuation scheme at 18 yers and over. Five day working week and flexible working hours scheme operated. Transport facility available mornings and evenings.

Further particulars and application form from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA quoting ref: 79/10.

Closing date 26th November 1979. 3717(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

DEPARTMENT OF BIOLOGY

POST-DOCTORAL POSITION

available immediately to study Host-pathogen interaction in plants. Training in Biochemistry and Plant Pathology preferable; $11,800 per annum or more depending on experience.

Applications, including curriculum vitae and names of three referees, should be addressed to Dr Arya K. Bal, Department of Biology, Memorial University of Newfoundland, St. John's, Newfoundland, Canada A1B 3X9; or call (709) 753-1200, Ext. 2694. 3686(A)

FACULTY POSITION

Organic Chemistry

Applications are invited for a tenured senior appointment which the Department of Chemistry at Stanford University expects to be able to make in the near future. Applicants must have outstanding research credentials in organic chemistry and a strong commitment to teaching undergraduates as well as graduates.

In applying, send curriculum vitae and bibliography to: Professor K.O. Hodgson, Department of Chemistry, Stanford University, Stanford, California 94305. Stanford is committed to Equal Opportunity through Affirmative Action in employment and we are especially eager to identify women and minority persons with appropriate qualifications.

Applications should be received by 15 December, 1979. W516(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL

DEPARTMENT OF HISTOCHEMISTRY

RESEARCH/SCIENTIFIC OFFICER

required to work on problems connected with the localisation and dynamics of peptide hormones and neuroendocrine regulation in man and experimental animals.

Applicants should be graduates (or equivalent) and must have experience in some or all of the following techniques: histology, histochemistry, electron microscopy, antibody production immunostaining.

The suitable candidate will have opportunity for specialising in a particular area and/or will be able to apply for a higher degree.

Salary, dependent on qualifications and experience, initially between £4,000 and £6,000 a year.

Further particulars and application forms may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W1 0HS quoting reference number 6/222/N. 3682(A)

NATURAL ENVIRONMENT RESEARCH COUNCIL
INSTITUTE OF TERRESTRIAL ECOLOGY

SCIENTIFIC OFFICER/ HIGHER SCIENTIFIC OFFICER

A Scientific Officer/Higher Scientific Officer is required by the Institute at Craighall Road, Edinburgh, to investigate the population dynamics and spatial distribution of zooplankton in shallow lakes.

QUALIFICATIONS

Candidates should have at least a 2.1 honours degree in Zoology, Ecology, Limnology, Mathematical Biology or a similar subject. Relevant experience is desirable together with an interest in freshwater biology. Candidates for HSO should have at least 2 years post graduate experience in a relevant subject for those with an Honours Degree or 5 years experience with HNC/HND. Mathematical ability and experience are essential.

SALARY AND CONDITIONS OF SERVICE

Scientific Officer:
£3,289 – £5,085 pa. From 1.1.80: £3,591 – £5,486 pa.
20 days paid annual leave

Higher Scientific Officer:
£4,727 – £6,211 pa. From 1.1.80: £5,097 – £6,737 pa.
22 days paid annual leave

Up to 22 days annual leave plus 10½ days public and privilege holidays.

Starting pay according to age, qualifications and experience.

There is a non-contributory superannuation scheme.

The Natural Environment Research Council is not a Government Department but conditions of service are similar to those of the Civil Service.

Application forms and further details are available from:
Establishments Section, Institute of Terrestrial Ecology, 68 Hills Road, Cambridge, CB2 1LA. Telephone (0223) 69745.

Closing date for completed applications is: 23 November 1979. Reference: 64.
3662(A)

UNIVERSITY OF LONDON
KING'S COLLEGE

DEPARTMENT OF CIVIL ENGINEERING

A RESEARCH ASSISTANT

is required to join a collaborative project with the Transport and Road Research Laboratory on the analysis and prediction of the structural behaviour of road pavements under repeated loading.

The appointment is likely to be at Post-Doctoral level and is for two years in the first instance. Adequate background and experience in analytical and numerical techniques is essential. Depending on age and experience, the starting salary for a post-doctoral worker will be at one of the first three points on the 1A scale (ie £4333, £4622 or £4910 pa) plus a London Allowance of £740 pa.

Applicants having good relevant experience, but without a doctorate, may also be considered. Applications, giving a brief curriculum vitae and the names and addresses of two referees should be sent to Professor J W Dougill or Professor K Nash, Department of Civil Engineering, King's College, Strand, London WC2R 2LS, either of whom will be pleased to give further details of the appointment.
3702(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF PLANT BIOLOGY

Applications are invited for the post of

DEMONSTRATOR

in the Department of Plant Biology. The appointment will be for a period of three years from 1st January, 1980. Candidates should have appropriate postgraduate experience and preference may be given to ecologists who have shown special interest in population biology. Duties will include teaching undergraduates and helping with field classes.

Salary will be at an appropriate point on the Grade 1B (Bar) scale: £3,775 – £5,488 per annum, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

No forms of application are issued, but applications (3 complete copies), giving full details of age, qualifications, experience and present salary, together with the names and addresses of 3 referees, should be lodged with the Senior Assistant Registrar, The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, not later than 30th November, 1979. (Preliminary enquiries may be made directly to the Head of Department of Plant Biology.) Please quote reference N. 3668(A)

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORATE ASSOCIATE

To work in the areas of prostaglandin metabolism or cultured cell-lipoprotein interactions. Salary will be $14,000 per annum.

Applications consisting of a curriculum vitae and names of two referees should be sent to Director, Postgraduate Appointments, Biochemistry Department, George Washington University School of Medicine, 2300 Eye Street, NW, Washington DC 20037, USA. (An Equal Opportunity Employer)
W521(A)

AGING AND MOLECULAR BIOLOGY

POSTDOCTORAL POSITIONS AVAILABLE

to study

i) aging of the transcription and translation processes in vivo or ii) bacteriophage development in anucleate cells.

Candidates should have experience in either enzymology, preferably RNA polymerase, in vitro transcription/translation systems, characterisation of DNA replication intermediates or bacterial/phage genetics. Applications with full C.V., research experience and names of referees to Dr J N Reeve, Dept. Microbiology, Ohio State University, Columbus, Ohio 43210.

An Equal Opportunity/Affirmative Action Employer. Qualified women, minority and handicapped persons, as well as others, are encouraged to apply.

CSIRO AUSTRALIA

Assistant Chief

Division of Human Nutrition Adelaide

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7000 employees – 2400 of who are research and professional scientists – located in Divisions and Sections throughout Australia.

General: Research in the Division of Human Nutrition is concerned with studies of nutritional processes with a view to identifying the existence and health consequences of nutritive imbalances and deficiencies in Australian diets. Its research includes experimental studies in inorganic nutrition and in metabolism and digestion, and epidemiological and behavioural studies with emphasis on the relations between nutrition, life-style, and human health.

Duties: To assist the Chief of the Division, Dr B S Hetzel, in the planning and development of research priorities. The appointment is sought of a senior scientist of proven achievement with a strong background in a laboratory discipline related to nutrition, preferably in some aspect of lipid biochemistry where there is already an active research group in the Division. Previous administrative experience is essential. The opportunity and resources will be provided to enable the appointee to pursue an active research role.

Tenure: This is an indefinite appointment which carries superannuation benefits, subject to normal conditions. However, the role of Assistant chief is offered for a term of three years in the first instance. The situation will then be reviewed to determine whether the appointee should continue as Assistant Chief for a further period, or as a senior research worker.

Salary: Principal Research Scientist/Senior Principal Research Scientist: $A23,991 – $A31,507 pa. Appointment at a higher level will be considered for a quite outstanding applicant.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 250/280 should reach:–

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 7th December 1979.

Applications in U.S.A. and Canada should be sent to: – The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 3690(A)

EDITORIAL ASSISTANT

Applications are invited from graduates in biochemistry or a related subject for the post of Editorial Assistant in the Editorial Office of the Biochemical Society in London.

Duties consist mainly in preparing typescripts for the printer and proof-reading for the various scientific publications of the Society. Applicants should have an interest in the presentation of the scientific text, although editorial office experience is not essential as training will be given.

The commencing salary will be £5,000 pa. Please apply in your own handwriting, with the names of two referees, to the Editorial Manager, The Biochemical Society, 7 Warwick Court, London WC1R 5DP.
3676(A)

ANGLO-EUROPEAN COLLEGE OF CHIROPRACTIC LTD

LECTURER

Applications are invited for the post of lecturer in Pathology, Microbiology and Haematology, as from 1st January, 1980.

The appointed person will be required to be responsible for the running of a small Clinical Haematology Laboratory in the College Clinic.

Applications together with curriculum vitae and the names of three referees to be sent to the Dean, Anglo-European College of Chiropractic, 1 Cavendish Road, Bournemouth, Dorset, BH1 1QX, as soon as possible. 3642(A)

CSIRO AUSTRALIA

Research Scientist

Division of Food Research Food Research Laboratory North Ryde

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7000 employees — 2400 of who are research and professional scientists — located in Divisions and Sections throughout Australia.

Field: Electron Microscopy.

General: The food Research Laboratory at North Ryde, NSW is part of the Division of Food Research. The research programmes of the Division include many aspects of the chemical, physical and biological sciences related to the handling, processing and storage of foods and to the needs of the food industry and the consumer. The Food Research Laboratory, which has a total staff of 175, is working on sensory aspects of foods, food structure, safety and quality, plant physiology and food technology.

Duties: To carry out investigations of biological and physical materials using light and electron microscopical techniques. The appointee will be encouraged to collaborate with other scientists on a diverse range of problems at the Laboratory and will be expected to develop an independent research programme.

Qualifications: A PhD degree or equivalent with experience of light microscopic, transmission and scanning electron microscopic and freeze-fracture techniques.

Salary: Research Scientist/Senior Research Scientist: $A15,916 — $A23,122 pa.

Tenure: Indefinite with superannuation.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 300/745 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 7th December 1979.

Applications in U.S.A. and Canada should be sent to: — The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 3689(A)

A POSTDOCTORAL RESEARCH FELLOW

is required in early 1980 to work for 1-2 years on a project sponsored by the Deutsche Forschungs-gemeinschaft on Cellular Interactions and early membrane events in mitogenic lymphocyte stimulation.

The salary is in the range of 40,000 Deutsche Mark/year.

Applications, consisting of full curriculum vitae, list of publications, and naming 2 referees should be addressed to: Dr W G Bessle, Lehrstuhl Mikrobiologie II Arbeitsgruppe Immunologie, Auf der Morgenstelle 28, D 74 Tuebingen, Fed. Rep. of Germany. W508(A)

RESEARCH ASSOCIATE (M.D. or Ph.D.)

To participate in a biomedical research project at Washington University School of Medicine involving regulation of protein synthesis. Experience in nucleic acid biochemistry and *in vitro* protein synthesis required.

Annual salary $12-15,000 plus benefits. Excellent working conditions. Apply to Carol Cassidy, Job Service Missouri Division of Employment Security, 4645 Gravois Ave., St Louis, Mo. 63116. Equal Opportunity Affirmative Action Employer M/F/H. W511(A)

UNIVERSITY COLLEGE DUBLIN

Applications are invited by the Governing Body of the College for the following full-time statutory appointment:

PROFESSORSHIP OF HORTICULTURE

Prior to application, further information (including application procedure) should be obtained from the Secretary and Bursar, University College, Belfield, Dublin 4. Telephone enquiries: 693244, extension 431.

The latest date for receipt of completed applications is Thursday, 13th December 1979.

3665(A)

UNIVERSITY OF RHODESIA

SENIOR LECTURESHIPS/ LECTURESHIPS

CROP SCIENCE (An Agronomist):
A vacancy exists for a suitably qualified graduate to teach courses in Crop Production to students enrolled for the degree of BSc Agriculture with Honours. Preference will be given to applicants with experience in tropical agriculture with specific reference to conditions pertaining in Zimbabwe-Rhodesia.

CROP SCIENCE:
A vacancy exists for a suitably qualified graduate to teach and conduct research in Crop Production, Plant Breeding, Plant Physiology, Plant Protection or Horticulture. Postgraduate qualifications and experience required. Knowledge of a local African language preferred. The candidate would be expected to initiate research relevant to increasing plant food productivity in the subsistence agricultural sector. Appointment initially for 3 years.

LAND MANAGEMENT (Soil Science):
Two lectureship vacancies, one in *Soil Chemistry* and one in *Soil Physics* exist in the Department of Land Management. The candidates would be expected to teach courses in their particular fields to Honours standards and to assist with other courses in soil science.

Salary Scales and Conditions of Service for Academic Posts:
Senior Lecturer
£6934 × 269—7741 × 286—9171 p.a.
Lecturer Grade I
£6289 × 237—7237 p.a.
Lecturer Grade II
£3883 × 204—4903 × 237—6088 p.a.
Approximate figures converted from Zimbabwe-Rhodesian $ to £ sterling as at 16.10.1979.
Appointment on the above scales is in accordance with qualifications and experience.

Permanent Pensionable Terms:
Family passages and allowance towards transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished accommodation is guaranteed for a period of at least three years for persons recruited from outside Zimbabwe-Rhodesia. Sabbatical and Triennial visits with travel allowances. Superannuation and medical aid schemes.

Short-Term Contracts:
Family passages and allowance towards transport of effects. Assistance with accommodation for persons recruited from outside Zimbabwe-Rhodesia.

APPLICATIONS (6 copies) giving full personal particulars (including full name, place and date of birth etc), qualifications, publications, employment and experience, present salary, date of availability and the names and addresses of three referees should be submitted to the Appointments Officer (Staff), University of Rhodesia, P.O. Box MP 167, MOUNT PLEASANT, Salisbury, Zimbabwe-Rhodesia.
Overseas applicants should send an additional copy of their application to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF.
Closing date for the receipt of applications is *15 December 1979.*
British subjects considering applying for posts in Zimbabwe-Rhodesia are urged to consult the Foreign and Commonwealth Office (tel: 01-233 4995) or their nearest British Consular Office. 3661(A)

FACULTY POSITION IN BIOLOGICAL SCIENCES

at the Hopkins Marine Station of Stanford University

Applications are invited for an appointment in the Department of Biological Sciences of Stanford University, to be resident at the Hopkins Marine Station in Pacific Grove, California. The position is without restriction as to rank although some preference will be given to younger candidates.

The position involves both teaching and research. The areas in which the Station wishes to expand its faculty include Cellular, Neuro- and Developmental Biology. All applications must include a curriculum vitae, a statement of research interests and a list of three people from whom letters of reference will be sought.

Applications should reach C S Pittendrigh, Hopkins Marine Station, Pacific Grove, CA 93950 by January 15, 1980. Stanford University is an equal opportunity employer. W505(A)

UNIVERSITY OF HONG KONG

LECTURESHIP IN MICROBIOLOGY

Applications are invited for a post of Lecturer in the Department of Microbiology. Applicants who are not medically qualified will also be considered.

Annual salaries (superannuable) are:
Clinical Lecturer
HK$68,580 — 72,060 — 83,340 — 87,240 — 91,320 BAR 109,920 — 114,840 — 119,760 — 124,680 — 129,600.
Non-clinical Lecturer
HK$67,920 × 4,560 — 77,040 BAR 81,600 × 4,560 — 113,520.
(£1 = HK$10.70 approx.). Starting salary will depend on qualifications and experience.

At current rates, salaries tax will not exceed 15% of gross income. Housing at a rental of 7½% of salary, education allowances, long leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, or the Recruitment Section, Secretary's Office, University of Hong Kong, Hong Kong.

The closing date for applications is *30 November 1979.* 3663(A)

UNIVERSITY OF GLASGOW

LECTURER (NON-CLINICAL) In the University Department of Medical Cardiology Royal Infirmary

Applications are invited for the above appointment. This post would be in biochemistry with particular reference to myocardial metabolism. Duties include participation in teaching and research. The department has a close liaison with the University Departments of Biochemistry and Pathological Biochemistry in terms of research projects.

Salary will be within the range £4,333 to £6,355 of the Lecturers' scale £4,333 to £8,992, with placement according to qualifications and experience.

Further particulars may be obtained from the Secretary of the University Court, (Room 18), University of Glasgow, Glasgow G12 8QQ, with whom applications (8 copies), giving the names and addresses of three referees, should be lodged on or before 7th December, 1979.

Enquiries may be made to Professor T D V Lawrie, University Department of Medical Cardiology, Royal Infirmary, Glasgow G4 0SF. In reply please quote Ref No 4537M. 3694(A)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF CHEMICAL PATHOLOGY

Applications are invited from graduates for a post of

RESEARCH ASSISTANT

for work on a project, funded by the S.R.C., investigating the genetic control of sexual differentiation in the mouse. Applicants should preferably have a good background in genetics, endocrinology or immunology. The appointment will be made for a fixed period of up to three years.

Salary at an appropriate point on the IB scale for Research and Analogous Staff (£3,775 to £5,488) (under review).

Informal enquiries will be welcomed by Dr A D Stewart, Department of Chemical Pathology, Old Medical School, Thoresby Place, Leeds LS2 9NL; telephone (0532) 32799 ext. 491.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 84/10/D. Closing date for applications is 29 November, 1979. 3691(A)

TRAINEE VACUUM TECHNOLOGIST

'A' LEVELS OR A SCIENTIFIC DEGREE?

Then the Daresbury Laboratory may have a vacancy to interest you.

The Laboratory is an establishment of the Science Research Council situated in the north Cheshire countryside. At present we are constructing a large tandem Van de Graaff accelerator for experiments in nuclear structure physics.

THE JOB

We need a man or woman with a scientific background to assist with R & D work assessing the suitability of commercial vacuum equipment and materials for use in vacuum systems. You would also be involved in commissioning and operating vacuum systems for the Van de Graaff; developing special vacuum control systems; and helping with high voltage breakdown studies.

QUALIFICATIONS AND EXPERIENCE

The appointment will be made at one of two levels: (a) as a Scientific Officer for which a good honours degree in physics or applied physics is required, HNC/D holders with relevant experience would be considered, or (b) as an Assistant Scientific Officer for which 4 'O' levels including English and Maths or Physics, are required. Candidates with scientific 'A' levels would be preferred.

Training will be given but some knowledge of vacuum techniques and of transistor logic systems would be an advantage.

There is a non-contributory superannuation scheme, a generous leave allowance and a flexible working hours scheme.

Closing date: 23rd November 1979.

Please write or telephone Warrington (0925) 65000 ext. 467, for an application form quoting reference No. DL/710/CB to:

The Personnel Officer

DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

3710(A)

THE UNIVERSITY OF PAPUA NEW GUINEA

Applications are invited for 2 posts of

SENIOR LECTURER/ LECTURER

in the

DEPARTMENT OF AGRICULTURE

Applicants should have a good first degree in Agriculture and experience, preferably at PhD level. Preference will be given to applicants with University teaching and research experience. Tropical agricultural experience would be an advantage. Applicants should have expertise in one or more of the following fields: agronomy of perennial crops, pasture agronomy, crop physiology under field conditions, agricultural ecology and/or crop botany.

The appointees will be responsible for courses within their fields of competence up to Honours degree level and may be required to assist in other courses and will be expected to supervise postgraduate students and carry out independent research. They may also be asked to assist with projects on the departmental farm and to undertake other relevant duties as may occasionally be assigned. Currently the department is split between Port Moresby and Lae, but from February 1981 will be unified in Port Moresby.

The appointees may be asked to teach one or two semesters in Lae initially, but will eventually be based in Port Moresby. Salary scales: Senior Lecturer K15,575 pa, Lecturer K13,725 pa (£1 sterling = K1.55). Family passages; baggage allowance; 3 year contract; a gratuity of 24% of which 5% is taxable; research support; rent-free accommodation; overseas leave; education allowances; medical aid scheme.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Assistant Secretary, Box 4820, University PO, Papua New Guinea by 14 December 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91, Tottenham Court Road, London, W1P ODT. Further details may be obtained from either address. 3700(A)

ROBERTSON RESEARCH INTERNATIONAL LIMITED

SEDIMENTARY GEOLOGISTS

Robertson Research International Limited have vacancies in their head office in North Wales for experienced sedimentary geologists. Applicants should be familiar with the full range of sedimentological techniques relevant to carbonates and/or clastics. The position is challenging with career prospects, and will require the successful candidate to work on individual assignments and as a member of a team. Work is concerned with the study and interpretation of rocks from oil prospective areas. Preparation of technical reports is an integral part of the duties and experience in this field is required. Salary will be competitive and negotiable depending on age, experience and qualifications. The position is permanent and pensionable. The closing date for completed application forms is 31st December 1979.

Please apply to: (Quoting Ref. P/13-2) Mrs Janet Hedges, Robertson Research International Limited, 'Ty'n-y-Coed', Llanrhos, Llandudno, Gwynedd, LL30 1SA, Gwynedd. 3677(A)

UNIVERSITY OF GEZIRA/SUDAN

Applications are invited for the post of

Lecturer

in Weed Science in the Faculty of Science and Technology.

Applicants must have a higher degree and relevant teaching and research experience in the area of weed research and chemical weed control. The appointee is expected to be engaged primarily in research and postgraduate teaching, although duties may include limited teaching at the undergraduate level. The appointment will be for a fixed term of two years with possibility of renewal.

The salary will be determined according to experience. This position is endowed by CIBA-GEIGY. Children's education allowance, health insurance, holiday visit passages, family passages, free housing, and annual overseas leave will be provided.

Detailed applications (3 copies) with curriculum vitae and naming 3 referees to be sent to the Vice-Chancellor, University of Gezira, P.O. Box 20, WAD MEDANI, Sudan. General information and conditions of service or contract may be obtained from this address. W509(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF SOIL SCIENCE

Applications are invited for the post of

LECTURER

in the Department of Soil Science tenable from 1st January, 1980. Whilst research experience in the use of physical methods for the solution of soil, agronomic or environmental problems would be particularly appropriate for this post, applications from those with interests in the broader aspects of soil management and fertility will also be welcomed.

Salary will be at an appropriate point on the scale £4,333 to £8,992 per annum, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar (F.P.), The University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, with whom applications (three copies) together with the names and addresses of three referees, should be lodged not later than 26th November, 1979. Please quote reference N. 3678(A)

Nature Vol. 282 8 November 1979

CSIRO AUSTRALIA

Research Scientist

Division of Plant Industry Canberra

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7000 employees — 2400 of who are research and professional scientists — located in Divisions and Sections thoughout Australia.

Field: The management of agricultural systems.

General: The Divisions, with headquarters in Canberra, carries out research in a wide range of plant sciences fundamental to agricultural production. Its Agricultural Systems Programme is concerned with developing more efficient systems of farming in the temperate high-rainfall zone, through a combination of experiments and simulation techniques. Of particular interest are the problems associated with grazing systems based on improved pastures and their integration with crop production. The Division has an Experiment Station and Animal House facilities within easy reach of Canberra.

Duties: The appointee will participate, with a team trained in agronomy, animal nutrition and simulation techniques, in a programme aimed at increasing the efficiency of mixed farming systems. In particular, he/she will be expected to devise methods of overcoming problems that limit animal production in temperate areas of the high-rainfall zone. The research programme will aim at defining deficiencies in herbage against the background of seasonal animal requirements. Its emphasis will be on ways in which shortages can be met through supplements, pasture improvement and the grazing of crops and stubbles.

Qualifications: A PhD degree or equivalent qualifications and training in an appropriate field, together with demonstrable research ability. Experience in the use of techniques for studying the nutritional status of suckling and grazing animals, will be an advantage.

Salary: Research Scientist or Senior Research Scientist $A15,916 — $A23,122 pa.

Tenure: Indefinite with superannuation.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 130/1459 should reach:—

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 7th December 1979.

Applications in U.S.A. and Canada should be sent to: — The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 3688(A)

Assistant Professor
Yale University
DEPARTMENT OF BIOLOGY

This Department invites applications for appointment beginning in academic year 1980-81 as Assistant Professor (level I or II) from persons with interests in molecular aspects of Genetics or Development. The appointee will be expected to contribute to a strong program of research and scholarship in Molecular Biology, and to participate in undergraduate and graduate teaching. Send curriculum vitae, resume of past and present research, and names of three referees by 1 January, 1980 to:

Chairman
Department of Biology
Yale University
New Haven, CT 06520

Yale University is an Equal Opportunity/Affirmative Action Employer
W518(A)

UNIVERSITY COLLEGE OF NORTH WALES
Bangor

CHAIR OF COMPUTER SCIENCE

Applications are invited for the post of

PROFESSOR OF COMPUTER SCIENCE

in the School of Mathematics and Computer Science.

The appointment will be from 1st October 1980 (or an earlier date to be arranged) and the salary will be in the professorial range.

Further particulars can be obtained from the Secretary and Registrar, University College of North Wales, Bangor, Gwynedd, LL57 2DG.

Ten copies of the application (one from overseas candidates) together with the names of three referees should be sent to reach the Secretary and Registrar by Friday, 14th December, 1979. 3680(A)

UNIVERSITY OF DUNDEE

Applications are invited for a newly established

CHAIR OF ZOOLOGY

in the Department of Biological Sciences. There is at present one other chair in the Department, the Boyd-Baxter Chair in Biology which is currently held by Professor W D P Stewart, FRS.

Further particulars are available from The Secretary, The University, Dundee DD1 4HN, with whom applications (ten copies or, if posted overseas one copy) should be lodged by November 22nd, 1979. Please quote reference EST/86/79J. 3576(A)

UNIVERSITY OF CAMBRIDGE

CAVENDISH LABORATORY

Applications are invited from suitably qualified physicists, chemists or metallurgists for a post doctoral research post jointly funded by ICI and the SRC under the Collaborative Award Scheme. The work is concerned with the structure and composition of very highly dispersed supported metal catalysts of enhanced activity and will provide an insight into the application of advanced research techniques to systems of direct industrial interest. Experience in electron microscopy and related techniques is required.

The appointment will be for two years, based in Cambridge but with about 10% of the period at the Corporate Laboratory of ICI at Runcorn. Salary is in the range £4333 — £5199 per annum. Applications should be addressed to the Secretary, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE. 3673(A)

KINGSTON POLYTECHNIC

SCHOOL OF CHEMICAL AND PHYSICAL SCIENCES

RESEARCH ASSISTANT IN HETEROCYCLIC CHEMISTRY

The work, supervised by Dr D T Hurst, will be concerned with the synthesis of pyrimidines and related compounds, the electrophilic substitution of pyrimidines, and studies of physico-chemical and biological properties of such compounds.

Applicants should have an honours degree, GradRIC or equivalent qualification, and if successful, will be expected to register for a higher degree.

Salary range £3,174 to £3,462 inclusive. Further details and application forms from Dept AO, Academic Registry, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366. 3696(A)

DEPARTMENT AND BIOPH...

The Department is undertaking ... ch for a relatively senior biophysicist (associate to full professor level) with rather broad interests and expertise in the general area of spectroscopy with possible, but not necessary, emphasis on nuclear magnetic resonance.

Prospective candidates should send their curriculum vitae and bibliography to Dr J Kent Blasie, Chairman, Search Committee, Department of Chemistry, 550 Chemistry Labs/D5, University of Pennsylvania, Philadelphia, Pa. 19104.

The University is an equal opportunity/affirmative action employer. W506(A)

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF PHYSICS & ASTRONOMY

POSTDOCTORAL RESEARCH ASSISTANT IN HIGH ENERGY PHYSICS

Applications invited for a post available immediately for a Physicist to work with a team participating in the experimental programme of the SPS accelerator at CERN, Geneva. Appointment initially in Geneva, participating in the design, installation, operation and data analysis of a recently approved hybrid emulsion-electronic experiment to search for B particles.

Salary in range £4,333 — £5,488 plus £740 London Allowance. In Geneva fares, housing and additional allowances will be provided.

Candidates should send details of their qualifications and experience, together with the names of two referees, to Dr B C Duff, Dept. of Physics and Astronomy, University College London, Gower St. London WC1E 6BT as soon as possible. 3701(A)

THE HATFIELD POLYTECHNIC

SCHOOL OF NATURAL SCIENCES

SENIOR LECTURER/ LECTURER II IN BIOCHEMISTRY

Applications are invited from suitably qualified candidates for a vacancy in the field of either Toxicology or Molecular Biology preferably including eukaryotic systems.

Candidates should possess an honours degree or equivalent qualification in Biochemistry or a related area, together with a postgraduate degree or substantial research experience. Industrial or other applied experience would be a decided advantage and applicants will be expected to be thoroughly conversant with the modern methodology and techniques involved in their field.

Salary scale: Lecturer II £4470 — £7149 + £72 supplement + £159 local weighting.

Senior Lecturer £6597 — £8253 + £72 supplement + £159 local weighting.

Application form and further details are obtainable from the Staffing Office, The Hatfield Polytechnic, P.O. Box 109, Hatfield, Herts or telephone Hatfield 68100 extension 309. Please quote reference: 298. Closing date: 23 November 1979. 3656(A)

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF BOTANY
GRADUATE RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant to work with Dr T ap Rees and Dr R A Leigh on the storage, metabolism and mobilisation of sucrose by vacuoles isolated from higher plants. Applicants should have a degree in biochemistry, botany, or a related subject. The appointment, which is financed by the SRC, will be for a maximum period of 18 months and will commence as soon as is practicable.

The starting salary will be £3,775. The successful candidate will not be able to register for a higher degree.

Applications, naming two referees, should be sent to Dr T ap Rees, University of Cambridge, Botany School, Downing Street, Cambridge CB2 3EA. 3697(A)

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF COMPUTER SCIENCE
PROFESSOR OF COMPUTER SCIENCE

Applications are invited for a second Professorship in the Department of Computer Science. To preserve the balance of interest in the Department, candidates with a knowledge either of Data Bases or the Theory of Computer Science are particularly encouraged to apply.

The post will be remunerated within the Professorial range for universities with USS benefits.

Application forms and further particulars (quoting 38/79) can be obtained from the Registrar, University of Strathclyde, 204 George Street, Glasgow G1 1XW, with whom applications should be lodged by 15 December, 1979. 3711(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF METALLURGY & MATERIALS SCIENCE
POST-DOCTORAL SENIOR RESEARCH ASSISTANT/RESEARCH ASSOCIATE

Applications are invited for the above post which is supported by the UKAEA Harwell and is tenable for two years. The area of research is intergranular fracture in iron based alloys and the objective will be to develop a fundamental understanding of the factors governing segregation of solutes to grain boundaries and their role in promoting grain boundary embrittlement.

It is expected that studies will be made of the thermodynamics of segregation and how this is related to composition and microstructure. The effects of segregated solutes on the work of fracture at grain boundaries will also fall within the scope of the work.

The appointee will be expected to spend periods at Liverpool and Harwell and will have access to surface analytical instruments, electron microscopes equipped for micro analysis and sophisticated mechanical testing equipment.

Initial salary will be on the scale £4,333 - £5,777 per annum.

Application forms and further particulars may be obtained from The Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, by whom completed forms should be received not later than 30th November, 1979. Quote ref. RV/830/N. 3666(A)

RESPIRATORY PHYSIOLOGY TRAINING PROGRAM
Funded by NHLBI
POST-DOCTORAL TRAINEESHIPS

available for one to three years. Areas of research include gas transport, red blood cells, microcirculation, neonatal physiology, aortic body and carotid body chemoreceptors, lung metabolism, lung cells, (type II and pleural) smooth muscle, lung innervation, tissue oxygenation, mitochondrial function and control of respiration.

Write to Education Officer, Respiratory Physiology Group, Department of Physiology, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania 19104. W517(A)

UNIVERSITY OF QUEENSLAND
Australia
SENIOR TUTOR IN ZOOLOGY
(2 positions)

Applicants should have a higher degree or honours with special interests in Invertebrate Zoology and/or Cellular Biology.

Salary: $A14,041 to $A16,085 p.a. Other benefits: Superannuation, housing assistance, travelling and removal expenses.

Additional information and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Closing date 22 November, 1979. 3684(A)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF MOLECULAR BIOLOGY
POSTDOCTORAL RESEARCH FELLOW

required as soon as possible to work on the molecular relationships of plasmids from strains of *Pseudomonas* and of enterobacteria. The methods currently being used include genetic manipulation *in vitro*, DNA-DNA hybridisation and electron microscopy of heteroduplexes.

The position is for two years. Further information from Dr P M A Broda (tel: 031-667 1081, ext. 2886) to whom applications should be sent with the names of referees and details of experience. Please quote Reference 5063. 3669(A)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF ZOOLOGY
HISTOLOGY TECHNICIAN (GRADE 5)

Candidates should have HNC or equivalent appropriate qualification and several years laboratory experience. The successful applicant will be responsible for preparing histological material for the teaching and research needs of the Department. Salary will be within the range £3,700 to £4,320 p.a.

Application forms may be obtained from The Registrar, The University, PO Box 147, Liverpool L69 3BX. Quote reference RV/837/N. 3692(A)

ASSISTANTSHIPS

WELLCOME SUPPORTED RESEARCH ASSISTANTSHIPS IN IMMUNOLOGY
UNIVERSITY OF CAMBRIDGE
Applicants are invited for
TWO RESEARCH ASSISTANTSHIPS

to participate in a research programme with Professor R.R.A. Coombs on sensitive methods for detecting antibodies and surface antigens.

One research assistant should be experienced in immuno-chemical purification, fractionation procedures and specificity control. The other should have experience in separation of lymphocyte subpopulations, lymphocyte stimulation, rosetting procedures and cell culture.

It is anticipated that the project will become operative on January 1st, 1980. Applicants should be under 28 at this date, possess a science degree, preferably also a PhD, and have distinctive laboratory experience. Salary up to £5,488 at 28.

Enquiries to Professor R.R.A. Coombs, Division of Immunology, Laboratories Block, Addenbrooke's Hospital, Hills Road, Cambridge, CB2 2QQ, and applications to the Laboratory Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP. 3715(P)

UNIVERSITY OF GLASGOW
DEPARTMENT OF NATURAL PHILOSOPHY
POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for an SRC funded post-doctoral research assistantship tenable for two years, to work with Dr E W Laing on computer simulation studies of compression of plasma to very high densities, in connection with Heavy Ion Fusion. Commencement date by arrangement, but not later than 1 February, 1980.

Initial salary in the range £4,333 to £4,910 (under review) on Range 1A of the scales for Research & Analogous Staff, plus superannuation.

Applications naming two referees should be sent by 1st December, 1979 to Dr E W Laing, Department of Natural Philosophy, University of Glasgow, Glasgow G12 8QQ, from whom further particulars may be obtained.

COURSES

EMBO
Advanced Laboratory Course on "Molecular Biology of Membranes"
co-sponsored by FEBS & SKMB
14-27 September 1980
Bio-Center, Basel, Switzerland

The course will include review lectures, specialized lectures and laboratory experiments. Main topics to be covered will include the physical chemistry of membranes, membrane reconstitution and analysis of membranes by biochemical, genetic and immunological methods.

Laboratory space will be available for 24 students. The course fee will include Swiss Francs 100 for registration and approximately Swiss Francs 500 for accommodation and food. Fellowships will be available. Applicants will be selected on a world-wide basis.

Application forms can be obtained from the organizers. Deadline for application is April 1, 1980. Organizers: G. Schatz and J Seelig, Biocenter, University of Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland. Tel. 061/25 38 80. W520(D)

UNIVERSITY OF LEICESTER
DEPARTMENT OF CHEMISTRY AND SCHOOL OF EDUCATION
Ph.D. in Chemistry with Graduate Certificate of Education

Applications are invited from persons holding, or expecting to be awarded during 1980, a degree with First or Second Class Honours (Upper division), or equivalent qualifications, in Chemistry, Combined Sciences, Chemical Engineering, Physics etc., who wish to pursue a 3-year course of research and teacher training.

The course may attract a limited number of Science Research Council quota awards, principally for new graduates, but candidates from industry or teaching may be eligible to apply for awards under other S.R.C. schemes.

For further information and application forms please write to Professor R D Peacock, Department of Chemistry, University of Leicester, LE1 7RH.

The closing date for applications is January 31st 1980. 3658(D)

FELLOWSHIPS

UNIVERSITY OF OXFORD
DYSON PERRINS LABORATORY

Applications are invited from organic chemists for a postdoctoral fellowship concerned with the applications of organometallic catalysts to asymmetric synthesis.

The appointment will be for a period of up to two years in Research Assistant Grade 1A, on a salary up to £4910, with membership of USS.

Candidates should write as soon as possible to Dr J M Brown, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY enclosing a full curriculum vitae and quoting the names of two referees. The starting date is flexible and final-year Ph.D. candidates will be considered. 3708(E)

FELLOWSHIPS and STUDENTSHIPS

Travelling Research Fellowships to Europe 1980-81

Applications are invited from British Research workers for the award of Wellcome-European Research Fellowships for 1980-81. These awards include the Trustees' special fellowships to Denmark, Norway, Sweden, Finland and Hungary.

The object of these fellowships is to encourage working visits to countries in Western and Eastern Europe by investigators in any branches of the natural and clinical sciences which have a bearing upon human or animal medicine. Candidates whose research is related to clinical problems will be given preference. These fellowships, which are normally for one year, are intended for *graduates from British Universities*, who already have some post-doctoral research experience. Stipends, according to age and experience, are within the range of £4,622 - £7,815 per annum. A special cost of living allowance applicable to the country in which the candidate wishes to work is given where necessary. Travelling and some incidental expenses are provided in addition.

Candidates must make their own arrangements with the department in which they propose to work, and written evidence must be submitted confirming their arrangements.

Application forms may be obtained from the Grants Section, The Wellcome Trust, 1 Park Square West, London NW1 4LJ. Telephone: 01-486 4902. Completed application forms must be returned by 31st December 1979.

The Wellcome Trust

3698(E)

THE ROYAL SOCIETY
E.P.A. Cephalosporin Fund SENIOR RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for the E.P.A. Cephalosporin Fund Senior Research Fellowship, endowed by the Trustees of the E.P.A. Cephalosporin Fund to provide a research fellowship in the medical, biological and chemical sciences. On this occasion applications are restricted to those working in the field of biological chemistry. The appointment will be tenable in any appropriate university department or research institution in the United Kingdom approved by the Council of the Royal Society. Candidates, who must be citizens of the United Kingdom or the Commonwealth, must supply the usual personal details and give two referees. Testimonials will not be considered. The subject of the proposed research, and where it would be done, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointment, which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from 1 October 1980 (or another date to be arranged) and may be renewable for one further five-year period. Applicants should preferably be under 40 on 1 October 1980. The stipend scale will be £9138 × £300 to £10 518 per annum, and the point of entry will be determined by Council. Superannuation benefits will be provided. Some provision for research expenses will be available.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG, and returned by 15 January 1980.

3699(E)

UNIVERSITY OF KENT AT CANTERBURY
APPOINTMENTS IN SPACE SCIENCES IN THE ELECTRONICS LABORATORY

Applications are invited for the following research posts tenable from 1 December, 1979 or as early as possible thereafter and financed by Science Research Council grants under the direction of Dr J.A.M McDonnell:

(1) A 3-year Post-Doctoral Fellowship for the development of instrumentation for the detection and analysis of cosmic dust on future space missions. Experiments for the joint ESA/NASA Comet Mission, Recoverable Space Shuttle Packages, Lunar Orbiters and Refurbishable Satellite Systems are planned. Relevant research experience in physics, astronomy, space research or instrumentation is desirable. Salary Scale: £4333 — £7521;

(2) A 2-year Post-Doctoral Fellowship for sensor calibration, mission development and data analysis in connection with the International or Solar Polar (Out of Ecliptic) Mission in collaboration with the Max Planck Institute, Heidelberg, and the Space Shuttle Recoverable Long Duration Exposure Facility. Suitable post-doctoral experience in space projects is essential for this post. Salary Scale: £4333 — £7521.

Application forms and particulars may be obtained from the Senior Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH to whom completed applications should be returned by 30 November 1979. Please quote ref. A44/79.

3716(E)

THE ROYAL SOCIETY
EUROPEAN SCIENCE EXCHANGE PROGRAMME FELLOWSHIPS

Applications are invited by the Council of the Royal Society for a research fellowship in the European Science Exchange Programme tenable in a laboratory in Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Republic of Ireland, Italy, the Netherlands, Norway, Portugal, Spain, Sweden or Switzerland. Candidates who must be of postdoctoral status by the time the proposed visit commences should have made preliminary arrangements for acceptance at the laboratory of their choice. Preference is given to newly or recently postdoctoral applicants, but candidates holding permanent appointments in the United Kingdom are also eligible to apply; in such cases the award will take into account any continuing salary which the candidate will receive.

Fellowship awards are normally made for 12 months, although applications for less than a full academic year but not less than 6 months will also be considered. Two-year fellowships may be awarded to a few outstanding candidates where the project merits this. Awards are based on the United Kingdom university lecturer rates plus local and married allowances.

The closing dates for applications are 12 January and 10 May 1980 and those interested should write for further details and an application form to The Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG.

3681(F)

POSTDOCTORAL POSITION

To work in transport of organic solutes in mammalian systems, membrane proteins and reconstitution of transport systems.

Please write to Dr R M Johnstone, Department of Biochemistry, McGill University, 3655 Drummond St., Montreal, Quebec, Canada, H3G 1Y6.

W504(E)

UNIVERSITY OF ABERDEEN
MILNER STUDENTSHIP

Applications are invited from candidates for this research studentship in the Department of Pathology tenable for one year in the first instance, with the possibility of extension for two further years. The research subject is a study of endothelial cell growth and reactions by tissue culture, autoradiographic and ultrastructural methods. Applicants should possess a good honours degree in some aspect of biology, preferably cell biology, pharmacology or physiology. It is expected that the appointee will register as a PhD student.

The value of the studentship and associated allowances will be broadly in line with those offered by the Research Councils i.e. in 1979-80 £1820 per annum plus University tuition fees.

Further particulars and information can be obtained from Professor A L Stalker, Department of Pathology, University Medical Buildings, Foresterhill, Aberdeen, AB9 2ZD. Tel: 0224 681818, extn. 2411.

Applications, with the names of two referees, should be lodged with the Secretary, The University, Aberdeen, by 30th November, 1979.

THE LEITZ DIALUX 20 – TODAY'S MICROSCOPE FOR TOMORROW'S DEVELOPMENTS

The LEITZ DIALUX 20 has been designed with an eye to the future development of microscopy: the established Leitz modular principle has been extended as a result of current experience: it is now even more practical, and offers optimum operating convenience with maximum functional reliability.

A considerably improved arrangement of the optical illuminating system makes the LEITZ DIALUX 20 even more efficient for all optical examinations of transparent specimens. It has been possible to enlarge the microscope field of view even further through the use of the excellently corrected series of LEITZ NPL FLUOTAR objectives. Amounting to more than 23% when compared with that of conventional microscopes – with critical definition across the entire image, this ensures that the new LEITZ DIALUX 20 is not only a reliable tool for diagnostic microscopy, but also a basic instrument that has the necessary reserves for biological research. We should like to convince you of the extremely favourable relationship between performance and price.

☐ I should like to know more about the LEITZ DIALUX 20 and would be pleased to receive full details.
☐ I should like to arrange a date for the Leitz consultant to visit me.

LKB 4400 Speed and Sensitivity with Style

29 JAN 1980

Using the latest technology to provide eye-catching design, solid-state heating for the horizontal analytical column and a high temperature reaction coil for fast colour development, the LKB 4400 Amino Acid Analyser is capable of performing fast analyses on small sample volumes at the picomole level. Indeed a complete protein hydrolysate analysis, including regeneration and equilibration is carried out in only 65 minutes. Physiological fluid analysis takes less than 4½ hours.

With its built-in 70 sample autoloader and optional data handling accessory, the 4400 Analyser can fully automate your chromatographic separation.

...the new honestly priced Liquid Scintillation and Automatic Gamma Counters from Philips...

...the end to price confusion.

Just how important is price?

Of course price is important. But not price at any price.

Price not as a result of your ability to beat the salesman down. With Philips you won't have to argue about price.

The Philips price is realistic. Our price is based on the value of our products.

No more – no less.

The new Philips Liquid Scintillation and Automatic Gamma Counters.

The new generation for the eighties.

In styling and performance.

In our price the availability of service is included.
For at least 10 years.

In our price the availability of spare parts is guaranteed.
For at least 10 years.

Compare Philips with others in this field.
For price and performance.

We invite your comparison.
To find out the facts fill in the coupon, or write, telephone or telex, but whatever you do, contact us.

Vitamin D Basic Research and its Clinical Application

Proceedings of the Fourth Workshop on Vitamin D
Berlin, West Germany, February 1979

Editors: A. W. Norman, K. Schaefer, D. v. Herrath, H.-G. Grigoleit, J. W. Coburn, H.-F. DeLuca, E. B. Mawer, T. Suda

1979. 17 cm x 24 cm. XXVIII, 1318 pages. Numerous illustrations. Hardcover. DM 220,–
ISBN 3 11 007712 4

This book gives a survey of present knowledge and research on numerous facets of calcium and bone metabolism. The problems are presented and discussed from various standpoints (biochemists, clinicians, osteologists). In addition, a report is made on the latest vitamin D research. The main point of these proceedings is the timeliness of each single contribution as well as the very informative summary of current problems of calcium metabolism, especially in reference to clinical aspects and perspectives. This book is of interest to those engaged in calcium metabolism, vitamin D research, problems of chronic kidney insufficiency, general osteologic problems, and endocrinology.

NICHOLAS COPERNICUS

VOLUME II ON THE REVOLUTIONS

AN ENGLISH TRANSLATION BY EDWARD ROSEN

It is nearly 500 years since Nicholas Copernicus, the father of modern physics, dedicated to His Holiness Pope Paul III, his theories on physics in De Revolutionibus Orbium Coelestium.

Now for the modern academic, unversed in mediaeval Latin, Professor Rosen has produced a new translation, together with a detailed commentary on the complete Latin text.

This is the 2nd volume in a planned 3-volume set of the complete works of Copernicus organised by the Polish Academy of Sciences. Printed and bound to a very high standard, it is a work of great scholarship and art in its own right, and a fitting companion to Volume I, the full-colour facsimile edition published in 1972.
£35.00 0 333 14530 5

MACMILLAN PRESS

Circle No. 12 on Reader Enquiry Card.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

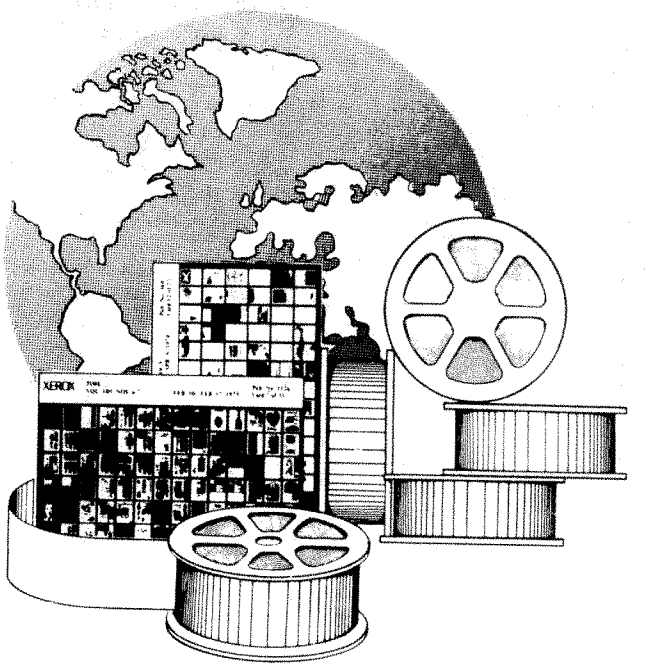
Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.



Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976).

INDEXES

Annual Indexes are available for the years 1971-1978. The year's papers are listed by both author and subject.

Prices: UK: £5.00
Rest of World US$10.00

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World: US$6.00,
three for US$16.00.

To order, please send details and correct remittance to:

Nature,
Circulation Department,
Macmillan Journals Limited,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

E"E. ' T E BA.IC OUTFIT OI. 'T: THE WAY TO MAXIMUM MICROSCOPIC PERFORMANCE.

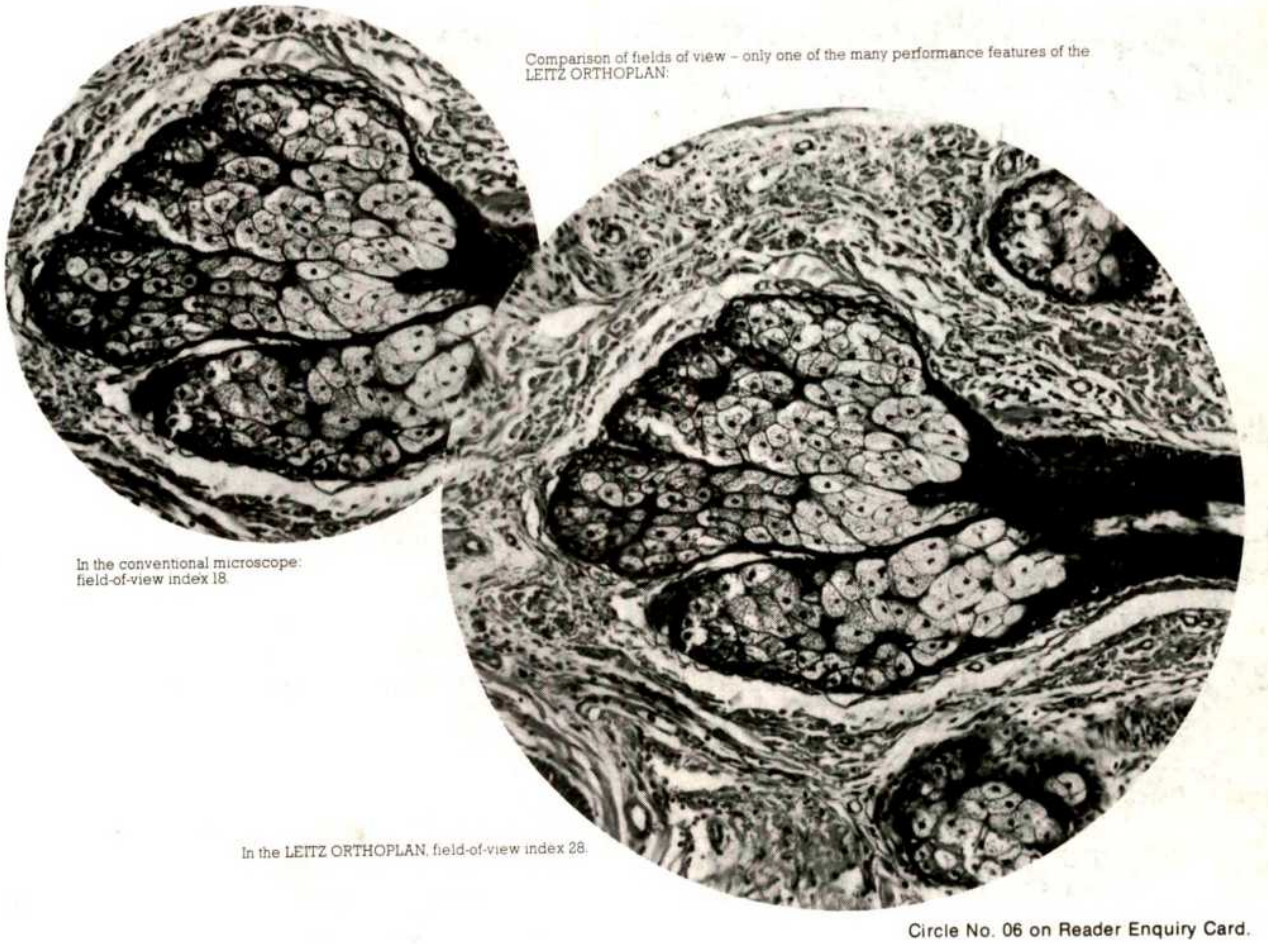
There are many valid reasons why research workers the world over decide in favour of a LEITZ ORTHOPLAN. The most important one is the LEITZ plan-apochromats, which produce images of unsurpassed resolution and edge-to-edge pin-sharpness. They also permit the utilization of a field of view which with large-field eyepieces is up to 140% larger than what has hitherto been possible to observe in a conventional microscope. This means more and better information at a glance, without the need to adjust the object.

There is not a single optical microscopic method of illumination and contrasting for which the LEITZ ORTHOPLAN cannot be adapted very quickly, to be instantly ready for any microscopic problem.

But the possibilities of the LEITZ ORTHOPLAN far exceed the field of classical microscopy.

They make this microscope the central optical component of all quantitative methods of microscope photometry with the LEITZ MPV system, and in electronic image analysis with the LEITZ T.A.S. the LEITZ consultant will be delighted to call on you and to demonstrate in your own laboratory how the LEITZ ORTHOPLAN can solve your special microscopic problems. All you have to do is send us the coupon below.

☐ I should like to know more about the LEITZ ORTHOPLAN and would be grateful for your detailed prospectus.
☐ I should like to arrange a meeting with the LEITZ consultant soon.



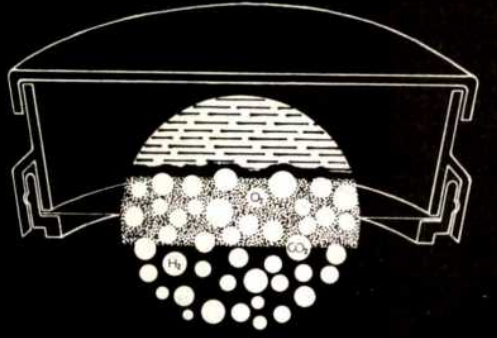
Name: _____

Address: _____

Please send this coupon or simply write to:
Information Service Ernst Leitz Wetzlar GmbH 409
D-6330 WETZLAR/Germany,
or to your national Leitz Agency.

Leitz means precision. Worldwide.

Comparison of fields of view – only one of the many performance features of the LEITZ ORTHOPLAN:



In the conventional microscope: field-of-view index 18.

In the LEITZ ORTHOPLAN, field-of-view index 28.

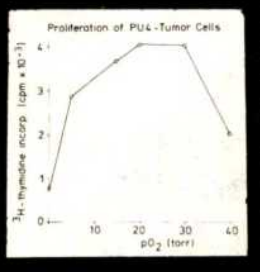
A new approach in tissue culture

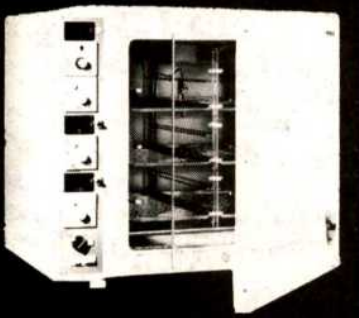


PETRIPERM

a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents



PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH, and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 µm thick membrane.

Heraeus— Co_2-Incubator B 5060 EK/CO_2

We build the incubator with appropriate pCO_2, pH and pO_2 control units

Call for Papers

PHOTOSYNTHESIS RESEARCH

an international journal, will publish reports from a very broad range of contributors without imposing artificial divisions between fundamental and applied research.

This new journal aims to provide a forum for original papers dealing with all aspects of photosynthesis research, including primary reactions, electron transport, photophosphorylation, carbon assimilation, structure and ultra structure, energy from biomass, regulatory phenomena and environmental and ecological aspects.

Papers on all aspects of photorespiration will be welcome, as well as papers on CO_2 fixation in CAM plants..

Papers will be considered for publication at all levels of plant organization: sub cellular, cellular, whole plant and canopy levels.

Editor-in-Chief is Dr. R. Marcelle, Laboratory of Plant Physiology, Research Station of Gorsem, Brede Akker 3, B-3800 Sint Truiden, Belgium.

All manuscripts submitted for publication should be sent to Dr. Marcelle.

Last chance for UNCSTD?

THERE have been two main reactions to the outcome of the United Nations Conference on Science and Technology for Development, which took place in Vienna in August. Some delegations returned home convinced that the conference had been a success; they support this claim by emphasising the amount of common ground established between developed and developing countries, and the general agreement on directions for future cooperation. Others, perhaps greater in number, returned feeling the conference had been a failure — but a qualified one. It had not resulted in any major shift in research towards Third World needs, or any particular clarification of what these needs are — but a framework had been agreed for pursuing both of these objectives.

Which of these two interpretations eventually prevails will depend on the outcome of the debates scheduled to take place next week at the UN General Assembly in New York. The Assembly's second committee will be discussing both the results of the Vienna conference, and the specific ways in which actions agreed by the conference should be carried out. Unfortunately many points of contention still remain, and it would be a tragedy if the short-term perspective engendered by the economic problems of the developed countries, as well as continued in-fighting within the UN system over future roles and responsibilities, placed in jeopardy the fragile achievements of Vienna.

There has already been some progress since the conference ended. The Director General for Development and International Economic Cooperation has prepared a detailed outline for the new intergovernmental committee (IGC) to oversee 'science, technology and development' issues. The Advisory Committee on the Application of Science and Technology to Development (ACAST), which despite recent criticism has considerable past achievement to its name, will be absorbed into a new body to advise the IGC. And the United Nations Development Programme, charged with administering the interim fund which the conference agreed should be set up on voluntary contributions totalling at least $250 million for 1980 and 1981, has produced a business-like prospectus outlining how it will carry out this role.

But it would be wrong to think that next week's meeting will be anything like plain sailing. There are several controversial issues still to be decided, in particular the division of responsibilities within the UN structure for science and technology activities, and levels of appointment and staffing to service the new committee. The Group of 77, which has been negotiating for the developing countries, is expected to present its proposals to the second committee outlining its veiws on these matters. And given their importance to both developed and developing countries — the Vienna conference, for example, was unable to agree on the specific role which the IGC should play with respect to the interim fund — heated discussion seems inevitable.

In terms of extra financial transfers, the situation looks even bleaker than it did in Vienna. Britain has just announced new foreign aid cuts which make it even more unlikely that it will be prepared to contribute to the interm fund when a pledging conference is held next February. The French position on an apparent commitment to increased UNDP contributions remains ambiguous. And Canada is reported to be having second thoughts about its proposal to shift funds within its aid budget to support joint research projects between Canadian and Third World research workers: Canada's International Development Research Centre, which had been expected to receive some of the new funds, is having its expansion plans closely scrutinised.

Perhaps the most alarming news comes from the United States, where the new Institute for Scientific and Technical Cooperation proposed by President Carter and offered as a centrepiece of the US presentation at Vienna is in serious defficulties in Congress. The Senate has refused to provide any funds for the institute's operation. Despite pressure from the House of Representatives, legislators seem determined to turn the ISTC into a sacrificial lamb on the altar of reduced public spending and federal bureaucracy. And its fortunes do not augur well for Congressional response to the $25 million request which President Carter is expected to make in January for the UNDP interim fund — already the source of considerable controversy in the State Department — over where the money is to come from.

Yet if there was one message to come through from UNCSTD, it was that helping to promote scientific and technological activities in the Third World is not a question of handing our blank welfare cheques — it is an essential prerequisite for a flourishing global economy.

The tighter the purse strings, the more difficult this will be to achieve. And ironically the more important it becomes to ensure that international mechanisms such as the UNDP and the new IGC can be made to work fairly and effectively. □

US scientists double estimates of ozone depletion rate

A COMMITTEE of the US National Academy of Sciences has calculated that the worldwide use of halocarbons may be depleting the ozone content of the stratosphere twice as fast as was predicted three years ago. A report published by the academy in 1976, calculating a depletion rate leading to an eventual 7.5% reduction in ozone, became the basis for a ban in the US, implemented at the end of last year, on all non-essential uses of chlorofluorocarbons, particularly those used as aerosol propellants.

Using improved computer models and better atmospheric and laboratory measurements, the panel on stratospheric chemistry and transport of the Academy's National Research Council now estimates the most probable eventual depletion as 16.5%.

Furthermore, using a model that assumes "an increasing release rate in other industrial countries" — rather than a release rate fixed at the 1977 level, the panel says it is "highly probable" that the eventual steady state reached would involve a 30% ozone reduction — and that this could be as high as 56.7%.

The panel points out that many uncertainties still surround such calculations. Since the release of earlier reports indicating the possible danger from fluorocarbon use, however, it points out that there has been a considerable improvement in both computer models and the quality of atmospheric measurements used to check their validity.

These activities have not altered the principal conclusion reached in the previous reports that continued release of halocarbons into the atmosphere will result in a significant decrease in the amount of stratospheric ozone," the report says.

Based on continued emission at the 1977 level the report says its own best estimate of the eventual ozone depletion is 16.5%. It adds that its estimate of uncertainty is such that there is a 95% probability that the true value of the ozone depletion lies between 5% and 28%. Ozone reduction to half the eventual level — to 8% — would occur in about 30 years, the report adds. □

Herbicide claimed responsible for birth defects

A US chemical trade union claimed last week that the exposure of male workers during production of the herbicide Oryzalin may have resulted in genetic damage to the children that they subsequently conceived.

According to the International Chemical Workers Union, of the four children born to men working in the plant in Rensselaer, New York State, over the period January 1975 to June 1976 during which the herbicide was being produced, three were born with heart deformities — two later dying — and one died from pneumonia two months later. There was also one miscarriage.

Oryzalin is the trade name for the chemical 3,5,-dinitro-N(4), N(4)-dipropylsulfanilamide. It is marketed in the US by Eli Lilly and co, which has denied that there is any evidence connecting the worker's exposure to the birth defects.

The company points out that no birth defects were indicated in laboratory tests carried out with rats and rabbits before the herbicide was approved by the Environmental Protection Agency in 1975. Nor was any evidence discovered after the question of a link to the human birth defects first raised in 1976. However, the assistant administrator of the EPA, Mr Steven Jellinek, said that the Agency was "very concerned" about the union's charges. Although the EPA did not know of any "scientifically established link" between exposure to Oryzalin and these health problems, the union's information indicated that there might well be some hazard, either from the herbicide or from some other substance to which the workers were exposed.

The union has asked the federal government to ban the production and use of Oryzalin, which is used on soybeans for weed control. "We are taking these actions to alert the public to the potentially devastating effects to future generations from exposure to this chemical" said union President Frank D Martino.

Mr Jellinke said that although no problem had shown up in the animal tests, the human experience indicating possible genetic problems with workers exposed to the herbicide "does raise questions". He said that the EPA will set up a team with the Occupational Safety and Health Administration and the National Institute of Occupational Safety and Health to study the effects of the herbicide, and that the report should be ready "within weeks".

Last week the EPA suspended all use of the pesticide DBCP while it decides whether to impose a permanent ban on the chemical, which has been linked both to cancer, and to sterility in male workers involved with its production. The administrator of the EPA, Mr Doug Costle, has ordered all applications of DBCP — most commonly used on fruit trees and soybeans — to be halted except in Hawaiian pineapple groves.

David Dickson

US sifts ex-Nazi scientists for possible war criminals

THE US Department of Justice, stepping up its search for Nazi war criminals who may now be resident in the United States, is investigating whether any were included in the 500 scientists and engineers who were brought over from Germany at the end of the second World War to work on weapons research.

No details have been given of the names of individuals under investigation. However, Justice Department officials confirmed last week that some of the scientists and engineers involved in what was known as "operation paperclip" are among the department's list of 200 to 250 suspected war criminals.

Under the programme, which operated from 1945 to 1955, over 3000 German and Austrian scientits who had worked for the Nazis were checked by US authorities to discover whether their skills could be of value to the US military efforts — and thus might also be of value to the Soviet Union.

Over 500 were subsequently brought to the US under a programme approved by President Truman, despite strong opposition from scientists such as Albert Einstein.

Since it was felt that it was in the interests of national security to bring them to the US, the scientists and engineers were admitted without having to pass the usual immigration and visa checks, even though some were known to have been members of the Storm Troopers, and the League of National Socialist German Physicians.

Perhaps the best known of those admitted were the members of the team which worked on guided missiles under Dr Werner von Braun, and were largely responsible for launching the first US satellite in 1958. However, the US also brought over experts from a variety of other disciplines, such as three scientists who had worked on the German chemical weapons programme, who went to work for the Army's Chemical Warfare Division.

Mr Martin Mendelsohn, deputy director of the Justice Department's newly-created office to investigate Nazi war criminals, said last week that membership of a Nazi organisation was not necessarily sufficient to invoke charges, which required evidence of war crimes. He confirmed that his office is now examining the files of all those brought to the US under operation paperclip to see if any cases should be pursued further.

A typical case demanding attention, according to a staff member of the Senate committee which is pushing the Administration for action on war criminals, is that of a former concentration camp medical officer who came to the US to work on a variety of aviation medicine projects. □

Rasmussen vindicated?

The Three Mile Island accident might have been prevented if more attention had been paid to a report on nuclear risk, but its message was clouded by disputes. **David Dickson** reports

ONE unexpected spin-off from the accident at the Three Mile Island nuclear plant last March has been a shift in attitude towards a report on the safety of nuclear reactors published in 1975 — the much-criticised Rasmussen Report.

Known officially as Wash 1400, and commissioned by the Nuclear Regulatory Commission, the report is usually referred to under the name of its principal author Dr Norman Rasmussen, now professor of nuclear engineering at the Massachusetts Institute of Technology.

When the report first appeared, the nuclear industry made much of the report's conclusion that the level of risk associated with nuclear power was relatively low compared to other energy sources. But it also received a barrage of criticism, in particular over the validity of broad conclusions drawn from limited data.

Much of this criticism was subsequently endorsed by a review committee established by the NRC, which repudiated some key sections. But the report of the President's Commission on the TMI accident, chaired by Dr John Kemeny and released two weeks ago, points out that the sequence of events leading to the accident supports Rasmussen's general analysis — with the implication that if more attention had been paid to the positive aspects of the report, the accident might have been avoided.

Professor Rasmussen is unapologetic about the report. He accepts that some aspects of the accident, in particular the extent of its psychological impact, were not predicted. But he points out that the report emphasises the dangers of concentrating safety planning on single major equipment failures, rather than on an accumulation of relatively minor failures compounded by operator error. "If anything, we were too conservative. We said that if the temperatures in the core went as high as they did, then we did not know if it would melt or not, but said it might have done. In the event the core did not melt, though a few more human errors would have caused it to do so."

Part of the problem is that there are, in a sense, two Rasmussen reports. The first is a detailed application of fault-tree/event-tree analysis to equipment failures in nuclear power plants. Even critics acknowledge this as an important contribution towards understanding risks. And the NRC review, carried out by a committee under Professor H W Lewis of the University of California, stated that the methodology developed "both can and should be more widely used by the NRC".

The second version of the report, however, is the one that was presented through the news media as carrying the principal message that nuclear power is basically safe. This conclusion, for example, helped persuade Congress to accept the Price-Anderson Act, limiting the liability of power companies in the case of nuclear accidents.

Professor Rasmussen is himself critical of those who over-sell the safety of nuclear power. "In the past there was a general tendency of public relations people to under-estimate the intelligence of the public, leading to the feeling that it was sufficient to issue warm pacifying statements rather than realistically portraying the risks and benefits of nuclear power. As the facts have evolved, however, the nuclear supporters have lost credibility, and many of their arguments are no longer believed."

Credibility has been at the heart of arguments over the Rasmussen Report itself. The Lewis Committee, following the lead of groups such as the Union of Concerned Scientists, criticised in particular the error bounds placed on the probabilities of various accident sequences.

They argued that these bounds were greatly understated, partly because of an inadequate data base, and partly because of an inability to quantify "common cause" failures, such as fire and earthquakes.

Professor Rasmussen defends his judgment. "I disagree with the Lewis Committee about margins of error. They found that the uncertainty was understated. I say that it might be understated in the safe direction, but I do not think it was greatly understated in the unsafe direction, because we already have 600 plant years of operating experience, and we have not melted a core. This gives an upper bound which is 30 times higher than ours".

It was the debates over the limits of uncertainty that led to the widest public criticism of the report. The NRC, for example, earlier this year issued a statement emphasising that as a result of its review "It does not regard as reliable the reactor safety study's numerical estimate of the overall risk of reactor accident."

Ironically, the vulnerability of the probability analysis seems to have resulted in that part of the report which was supported by the Lewis Review not getting the attention that it deserved.

A report prepared by the technical staff of the Kemeny Commission says that Wash 1400 contained three important messages. These involved the expected frequency of accidents (the TMI accident was well within the predicted range), methods for improving reactor safety through, for example, the use of fault-tree analysis to identify weak links, and the most likely types of accidents.

Rasmussen: unapologetic about the report

"Perhaps it is a fault of the report that these messages were not emphasised, because the conclusion most often associated with Wash 1400 — reactors are safe — receives the primary emphasis in the report. Perhaps it was the fault of the NRC that more effort was dedicated to criticising Wash 1400 than was applied to understanding its messages," the technical report (which does not necessarily reflect the Commission's views) says.

Rasmussen's critics argue that the construction of the report made it directly vulnerable to lop-sided interpretation. According to Dr Frank von Hippel of Princeton University, many scientists who read the executive summary of the report — also criticised by the Lewis Committee — "were infuriated by its Madison Avenue tone."

"If you follow the report backwards, from the appendices to the report itself to the executive summary, you find that at each level the qualifications and uncertainties of the previous level are dropped, so that what comes out is misleading because of what is omitted," he says.

Professor Rasmussen accepts some of the Lewis criticisms — but repeats that the TMI accident underlines the report's main conclusions. "The anti-nuclear people were able to use the accident to their advantage. But you can draw some satisfaction for both sides. Utility operators are now more prepared to listen to suggestions about safety than they were before, and on both the regulatory and the operating side, the event will lead to substantially reduced risk."

The accident had done nothing to change his support for nuclear power, a position now frequently expressed on public platforms. "Every new technology, when it was poorly understood, has attracted its doomsday prophets. Mostly this opposition has died away, and I suspect that nuclear power will probably go the same way. If we do not go on building nuclear plants, we will soon have major problems with the reliability of our power supply." □

Swedish firm in recombinant DNA storm

RECOMBINANT-DNA research in private firms in Sweden has got off to a very shaky start. The only firm to have applied to use the technique is threatening to move abroad if permission to go ahead is not given.

The firm concerned, KabiGen AB, is half owned by the state pharmaceutical company Kabi Vitrum, and half by private interests. It was set up in 1968 to investigate new sources of raw materials for Kabi Vitrum and is currently researching the production of human growth hormone by recombinant DNA techniques. Recently, the firm applied to the Hybrid-DNA Committee for permission to go ahead with further development. Permission was given to carry out the work P3/EK1 or P2/EK2 conditions under the revised NIH guidelines.

Kabigen already had a virology laboratory nominally between P3 and P4 standards; but as there were small parts of it which could collect dust, the firm announced that it would rebuild it. But an article in a Stockholm daily paper, written by the chairman of the Centre Party organisation in the same area as KabiGen, was very critical of the firm's plans to build the laboratory, especially as it is in a densely-populated part of Stockholm, and demanded that nothing be done until the whole issue had been debated publicly.

KabiGen's director, Dr Bertil Aberg, said that the firm's existence hinged on the laboratory being built and that the research would be moved abroad if the local health and building authorities did not approve the proposed changes and give permission for recombinant-DNA work to be done there.

The Centre Party — the carrier of the Swedish anti-nuclear banner — drew a parallel between the two issues, saying that unless there is a public debate now, recombinant-DNA research would become the nuclear debate of the 1980s. But the Party had not checked its facts. While claiming that KabiGen was proposing to build a "high risk labortory . . . without counterpart in Sweden", it was evidently unaware that there are already 25 P3 laboratories within a five-mile radius of Stockholm, handling dangerous pathogens in the State Bacteriological Institute and in local hospitals. It is doubtful, too, whether making minor alterations in the existing laboratory could be called "building". In spite of this, Dr Aberg seems to regret his initial openness. "KabiGen is the only industry using recombinant-DNA techniques", he told *Nature*. "Universities are doing a great deal of work with them, but they are very wisely keeping quiet about it."

However, this is not strictly true. All universities and private industries have agreed to inform the Hybrid-DNA Committee, set up in 1975 under the Natural Sciences Research Council, of any recombinant-DNA research they want to do. The committee then advises them about security levels. However this system will shortly be changed, if a bill proposed by the previous Liberal government is passed by the new Liberal-Centre-Conservative coalition. The bill is based on a one-man investigation of whether recombinant-DNA research can be carried out under Sweden's present laws. It proposed that a new body, to be called the Biotechnical Committee, be set up under the present Labour Protection Board, to advise the Board whether specific experiments may be done and under what conditions. It would also follow international events in the field and keep the Board, government and public informed of developments.

According to the Bill, the committee should be composed of specialists in genetics, microbiology, biochemistry and plant breeding; representatives of the Social Welfare Board, Nature Protection Agency, relevant research councils, trades unions and employers' federations. The chairman of the committee should be the Director of the Labour Protection Board. The bill does not specify exactly how many members the Committee should have; but the report on which it is based suggested a composition which put the scientists in the minority. Until a decision on the new system can be taken, there is a moratorium on new recombinant-DNA work.

Predictably, many members of the present Hybrid-DNA Committee (which has eleven members: seven scientists, one research engineer, one laboratory assistant and two Members of Parliament) are very critical of the proposed system. Professor Peter Reichard, the Chairman of the present committee, told *Nature* cautiously that "the new system won't be better than the present one." Other scientists were more forthright. "The new system would be enormously dangerous", declared Professor Lennart Philipson of Uppsala University. "It would be very bureaucratic: totally impossible. How much should you let public opinion aroused by newspapers influence the work of governmental agencies? Everything will depend on the people on the committee. How much common sense will they have?"

Wendy Barnaby

Avowed Nazis attack Brazilian physicists

A group calling itself the Movement for Nazi Renovation (MRN) has physically attacked scientists and intellectuals in Brazil. In a letter sent to the press they "take the responsibility for the terrorist attack upon the house of Mario Schemberg and his wife Lourdes Cedran". Schemberg is President of the Brazilian Physical Society; his wife was beaten up last month at her home by two men. At the same time several other jewish physicists and artists received anonymous telephone calls.

The MRN criticised these people, some "for having international prestige, for being jewish and as such diabolic", and others "for being living filth and all against the nuclear agreement" (between Brazil and Germany). The MRN also declared itself "against the feminist movement which, although pure nonsense, stimulates women to disobey men and have ideas of their own." The letter proclaims that MRN is "in favor of the nuclear agreement and of the arian race reassuming its historical role, specially in the military domain."

"The situation is quite serious", Professor Jacques Danon of the Brazilian Centre for Physics Research in Rio declared in a manifesto signed by all members of the centre: "A professor of sociology from Campinas was abducted last week and forced to drink castor oil . . . What is most worrysome is that the government is trying to minimize these terrorist attacks."

The head of the Security Police of Sao Paulo declared that one should not be concerned about "a joke done in bad taste", while the influential ex-minister of education Passarinho declared that the whole "affair" was unimportant.

The scientific community is apprehensive. The end of formal political repression had indeed led to open criticism of Brazil's gigantic nuclear agreement with West Germany which involves the construction of eight 1000 MW nuclear power stations in the next five years (*Nature* 2 August 79). The physicists presently under attack have all been particularly vehement in their opposition to the government's nuclear option for Brazil.

Recently Professor Cerqueira Leite said that the president of Nuclearbras, the government company which administers the nuclear contract, had gone from being a "nuclearcrat" to being a "nuclearpath" in accusing the physicists of participating in an international conspiracy against Brazilian interests allegedly involving both the United States and the Soviet Union.

The scientists are demanding in their manifesto that the authorities take the situation seriously. In the words of professor Danon, "even if MRN consists of a few crazy individuals, the government must prove that it has the will to act against them; otherwise some of our colleagues will be found dead tomorrow."

news in brief

Research funds sought for Three Mile Island clean-up: The owners of Three Mile Island nuclear plant said last week that they were negoatiating with the Department of Energy over Possible federal support for the Clean-up following last March's accident as a research project, on the grounds that the work will be "a covenient way of learning more about reactor safety". Mr Herman Dieckamp, President of the General Public Utilities Corportation, told a Senate Committee that the DOE was planning to fund research that could be conducted either at the TMI plant; or on materials from the site for which the government would pay the utility company access fees and materials costs. Typical research projects might include the development of decontamination methods, studies of hot core behaviour and removal and experimental work on damaged fuel pellets. "This is an important opportunity to add to the nation's nuclear expertise", Mr Dieckamp said.

"Remember to keep the computer informed every time you wring out your mop!"

AAAS executive foresees greater state direction over science: "I suspect strongly that the 1980s will see the main directions of science and technology decided by government" Mr William Carey, Executive Officer of the American Association for the Advancement of Science, said in Washington last week. Addressing the annual conference of the Society for Social Study of Science, Mr Carey said that the US was already far down that road, since the federal government paid more than half of the national bill for research and development, and influenced the rest through regulatory, tax and fiscal policy. "The illusion of partnership between government and academic science remains a lovely but abstract image, but it is not (if it ever was) an equal partnership". Domestic and international problems meant that this relationship would be "tortured progressively in the coming years". There was likely to be a rapidly growing social preference for centralised government, at the expense of pluralism and checks and balances. And one of the great tests would be that of holding on to such negotiating authority as science still possessed in its bargain with society.

Birmigham University not guilty in smallpox case: Birmigham University was found not guilty last week of health and safety violations arising out of the smallpox outbreak last year that killed Mrs Janet Parker, a university photographer. Parker was working on the floor of the pathogen laboratory of Professor Henry Bedson and the prosecution alleged that Parker caught the disease from airborn particles carried though a faulty ventilation system. Witnesses for the university rejected the argument saying that they were unable to assign a cause to Parker's death other than "personal contact". The UK Health and Safety Executive who brought the suit called the result "disappointing". The HSE is considering an appeal.

UK medical researchers lobby parliament: British politicians who met with representatives from the Association of Researchers in Medical Science on 8 November said that while they sympathised with the problems of short term contract workers they "were not sure that it was a matter for government". One hundred representatives of research workers in the UK marched to the House of Commons after presenting a petition with 1300 signatures to Mr Mark Carlisle, the Minister for Education and Science. A succession of MPs were "amazed" that they had "never heard of this before" but they wanted explanations about the particular situation of researchers compared to other groups in difficulty, why the trade unions weren't involved and they told the representatives that "researchers need to be very much clearer about they want to do". One MP offered to meet with ARMS and the Medical Research Council but when questioned about the efficacy of such a move said that he "wouldn't want to get into a confrontation with the MRC". As a result of the meeting ARMS will prepare a detailed brief of its proposals for a career structure for non-medically qualified researchers by Christmas.

Two thousand protest reorganisation of French biomedical research: In an open letter to the Prime Minister, 2000 French biomedical researchers have opposed "with profond emotion" the new governmental directives on scientific employment — particularly in INSERM, the national institute of health and medical research. Three hundred researchers demonstrated outside INSERM on 6 November for the meeting of its Administrative Council. According to *Le Monde* the signatories include 195 university professors and hospital doctors, 205 directors of research (including 89 INSERM unit directors), 81 heads of hospital services, 13 presidents of teaching and research establishments, 4 professors of the College de France and "one Nobel laureate". The principle points of contention in the new directives are the age limit on recruitment (27 years for researchers, 30 for doctors), a "forced mobilty" plan which would give the government the power to assign researchers to any laboratory and new restrictions on promotion when reseachers are needed on "priority projects".

Space Shuttle faces further delays — and legal probe: Nothing seems to be going right for the Space Shuttle, which the US National Aeronautics and Space Administration plans to have flying by the middle of next year. Last week another engine was severely damaged during testing at NASA's National Space Technology Laboratories in Bay St Louis, Missouri. No official statement of the impact on the Shuttle programme has been made, but it could delay the first launch, already a year behind schedule, by a further two to three months.

On top of this, the US Department of Justice announced last week that it was investigating charges that Rockwell International, the main contractor for the Space Shuttle, had hidden cost overruns on development aspects of the programme in later production budgets — and that this may have contributed to the delay in the cost-overruns now estimated at 20% above the initial estimate of $5.15 billion.

US Congress approves $20,000 million programme to develop synthetic fuels: President Carter won a major victory for his energy proposals last week when the US Senate approved administration-backed legislation to spend $20,000 million on the development of synthetic fuels over the next five years. The Senate also approved expenditure of a further $14,000 million for conservation measures and the use of solar energy and gasohol — including a commitment to speed the development of fuels from agricultural and forest products, a move enthusiastically supported by the US farming community. The Bill approved by the Senate, which has been sent to the White House for signature following the passage of a similar measure in the House of Representatives last Friday, sets a target goal of 1.5 million barrels of oil equivalent of synthetic fuels a day by 1995. President Carter had initially proposed spending $88,000 million on synthetic fuel development over the five years, but subsequently gave his support to the reduced programme. Included in the programme is an Energy Security Corporation which could build three government owned synthetic fuel plants.

Views of China are as diverse as its visitors. Here Tilman Spengler, who is responsible for scientific exchanges between China and West Germany's Max Planck Institutes, argues that the positive aspects of the Cultural Revolution have been forgotten, while Ken Hsu, (opposite), an expatriate geologist just back from China, lambasts that period and welcomes its passing. In a series beginning later this year, our China correspondent T B Tang — who has also recently visited China — will describe how science remains an intensely politicised activity, despite the impression in the West that the 'Four Modernisations' are loosening overtly political constraints.

China: the legacy of the Cultural Revolution

Involving workers in science during the Cultural Revolution

"THE Gang of Four", a Chinese solid state physicist told me happily in early 1977, "have always insisted that Marxism provides the foundations for solid state physics. That has changed. Today we can again point out that Maxwell equations are of some importance too".

The scientist had the laugh on his side. The other side, the 'Gang', eponym in today's China for every irresponsible ideological nincompoop, had lost their final battle. With the purge of 'The Four' in October 1976 the Cultural Revolution had for most practical purposes come to an end. As time went by, more and more tales of horror about persecutions and harassments of scientists, and accounts of vandalism in laboratories and libraries were revealed in the Chinese press (and to visiting colleagues from abroad). The message — at least as far as science was concerned — left little room for doubt: the Cultural Revolution hadn't just led to a mess, it had ended up in a (sometimes bloody) disaster.

The stories are indeed frightening even if some of them do contain exaggerations — and they should make some Western observers (including an uncomfortably high percentage of natural scientists) think at least twice how they could have eagerly adopted and retained the image of a happy Chinese scientist, cheerfully abandoning his or her research in, say, astrophysics, and discarding all social privileges to become part of the labouring many.

There may have been some exceptions, like a biochemist I met last year in Shanghai who preferred working on pesticides in the countryside to solitary confinement in his unit (he is by training an expert in neurophysiology). And there are others who admit that "it did us good" to experience the hardship of having to plant rice sprouts ten hours a day in a paddy field, the common lot of many of those who provide the funds for whatever research is being conducted in the country's laboratories. On the whole, however, the leaders of the Cultural Revolution were apparently singularly unsuccessful in their dealings with China's scientific community. The revolutionaries had a clear idea of what they did *not* want: elitism among intellectuals, international orientations, discipline rather than project oriented research, a system of social values that would perpetuate the division between manual and mental labour, material rewards, and so on. And they hoped to overcome all the traditional obstacles to a "planned science" geared to the country's socio-economic developments by creating the model of a selfless scientist who, by the very nature of his motivation 'for the cause', could do without the common academic incentives (reputation and to lesser degree remuneration).

As we have seen, sticks rather than carrots were used — sticks that Red Guards and a new generation of cadres had little hesitation in applying to individuals and institutions alike. And the Academy of Sciences, hitherto the most powerful and prestigious research organization of the People's Republic made no exception to the rule.

But was that all there was to it? Is the Chinese press justified in blacking out the decade between 1966 and 1976 as the uncontrollable reign of a few malevolent poltergeists, beset by chauvinism (or at least parochialism) and bent on keeping China in a state of unenlightened autocracy?

A number of facts contradict this new projection. Take, for example, the issue of internationalism. Most of the contracts between the Chinese Academy of Sciences and foreign research organisations, leading to exchange programmes of varying intensity, were begun long before October 1976. Another example is the issue of fundamental research, claimed to be one of the main targets of the science policy of the 'Gang'. Yet high-energy physics has been a priority in Chinese science politics ever since 1972 — and it takes a rather sophisticated understanding of the 'needs of the masses' to include high-energy physics. There were also a number of institutes within the Academy that worked very well, including the Institute of Botany, located in Kunming and set up to investigate the tropical plants of Yunan province. Even by western standards, this institute is (and was) well equipped, combining extensive empirical researches with highly competent analyses in pharmacology. Others were the Institutes for Vertebrate and Invertebrate Palaeontology in Beijing (Peking) and Nanking, or, to move to the social sciences, the Academy's (now the Academy for Social Science's) Institute for Archaeology, again in Beijing. Of course, these examples cannot be multiplied at will,

0028-0836/79/460224-03$01.00

©1979 Macmillan Journals Ltd

but they might make us pause for a moment before we join the chorus of lamentation.

And one should not pass lightly over the various mass campaigns to integrate research, education, health and safety, and production. Again a few examples: in mathematics, it was the "Movement for Operational Research" (yunchouxue yundong), and in oncology the emphasis on epidemiology. One could further add mass experiments and observations in plant pathology and earthquake research.

Let me briefly elaborate the last-mentioned example. Even before the Cultural Revolution, earthquake research had included a variety of specialists, such as mathematicians, geophysicists, geologists, seismologists, architects and historians. Their projects ranged from the adaption of seismographic scales to the pecularities of the structural engineering aspects of Chinese buildings, to the compilation of a chronology of earthquakes in the history of China which would then be used to divide China into different earthquake regions, as well as planning apartment houses and public buildings which would permit maximum resistance to earthquakes. During the Cultural Revolution this project was extended to include research teams of botanists, zoologists, and meteorologists. They investigated striking changes in fauna or flora which had traditionally preceded earthquakes, and changes in the ozone content of the air, which likewise serves as an empirical indicator for the threat of an earthquake.

Taken by itself, the addition of the last named group would hardly have constituted any startling departure from the previous forms of organisation. The decisive difference resulted from the widening of the area of inquiry to a level where literally "the masses" could participate. This type of horizontally and vertically integrated research was aimed not only at coordinating many individual talents to deal with a given problem (a social problem translated into a scientific problem), but was also intended — and this was the special message during the Cultural Revolution — to emphatically stress the importance of practical experience, its identification with science and its value for new orientations of action. Thus it encouraged a significant number of peasants to set up and maintain, in their own villages or production brigades, observation stations for early warning signs or earthquakes, on which they provided data. This brought about quite a considerable change of consciousness. Ordinary day-to-day routines acquired the dignity of scientific observations, and as a result reduced much of the traditional mistrust in, and resistance to, 'science' as something alien to their concerns. Equally important, the adherence to mythological or cosmological explanations which had enjoyed widespread popularity in the Chinese countryside, declined decisively. Natural phenomena had become interpretable in a new context. And this had a third result: the increased survival chances of a people who had learned to replace fatalism by practical planning.

The case of earthquake research probably serves best to illustrate the promises and the limitations of the Cultural Revolution's policy. The promises I have demonstrated: a research that would overcome disciplinary boundaries, answer to a huge social demand, integrate the participants and demanded no great financial investments.

But the limitations are equally clear. Taken as a paradigm for the only legitimate type of research, it would yield results only in those problem areas where everyday data play an mportant part in the solution, thereby leaving most of the 'mature' disciplines at the wayside. And 'maturity' is under no political conditions an argument for disposal, as the Chinese have had reason to find out.

Tilman Spengler

Tilman Spengler is a sinologist working at the Max Plank Institut fur Erforschung der Lebensbedingungen der Wissenschaftlich — Technischen Welt, Starnberg, West Germany.

THE vast arms of China's State Bureau of Geology (SBG) embrace 29 provincial bureaus, more than 20 research institutes, numerous exploration teams, and several institutions of higher education in earth sciences in addition to its headquarters at Peking. Earlier this year, I spent five and a half months as a 'guest expert' of the SBG, and I visited several of these branches in my capacity as a non-paid consultant to help 'modernise' geological activities in China. Usually oral presentations by Chinese colleagues, on which I was expected to give my opinions freely, were followed by outdoor discussions in the field. I would also sit with senior scientific staff and administrators to work out plans to orient future activities. Other duties involved lecturing, including a four-week course on plate tectonics and sedimentology to more than 400 geologists from 91 organisations and hours of subsequent informal discussions.

It has been estimated that China has more than 20,000 geologists. I could not have met more than 10% and talked to more than 1% of the total, and my sampling was not random, so my evaluations should be biased on the optimistic side. However, the reports I heard were not show-pieces, as were presented to us in 1977 when I was a

member of the visiting delegation of the International Union of Geological Sciences. I am, therefore, inclined to believe that I did manage a glimpse beneath the superficial during this particular trip.

If I had to use one word to characterise the level of the geological profession in China, the word would be uneven. Our Chinese colleagues are rather up-to-date in offshore exploration geophysics, exploiting much modern equipment, and it is not surprising that their efforts here have been repeatedly successful. On the other hand, sedimentologists in the same office were still using the methodology of the 1930s. *Erratic* is an apt word to describe the equipping of laboratories. They are commonly well endowed with instruments to analyse material properties of samples, but inadequately equipped to gather data that promote understanding of principles, or of geological processes. In an organisation where Quaternary studies form the essential basis for stratigraphical interpretation of potentially oil-bearing strata, its laboratory is not equipped for paleomagnetic studies and does not have a scanning electron microscope for

Ken Hsü — pictured above right — is a Chinese Scientist working at the Eidgenössische Technische Hochschule, Zurich. He visited China last August.

nannofossil investigations. Its pollen-laboratory is also inadequate, yet a neutron-activation apparatus has been acquired for microchemical analysis.

There is also a woeful lack of coordination among institutes. Each organisation would like to have its own 'small and complete' laboratories. Administrators were often faced with requests from several institutions for the same expensive equipment, which none of them could utilise fully. The idea of joint ownership and joint research projects among various SBG units was not explored, not to mention cooperation between SBG geologists and those of other systems. The situation became painfully obvious at Tsingtao, where I had contacts with marine geologists and oceanographers from four different systems. Funded separately, each may be able to purchase equipment of the 1950s and 1960s vintage, yet none considered seriously the possibility of combining resources to set up a common up-to-date facility for a national programme on oceanography.

Less visible, but more serious than the problem of modernising equipment is the need for modern methodology. For example, the basic tools of a field geologist — hammer and compass — have remained unchanged for the last century, and it was thus difficult to convey the idea that the methodology for field geology had made advances until we went to the field together. There, I could point out the irrelevance of worrying if a boundary between formations X and Y should be drawn at the base of a bed A, or a few metres higher. Nevertheless, it was not an easy task to persuade our young colleagues to give up their naïve reliance on specific indices, for example that glauconite proves marine deposition even if only a trace is found after a week of searching.

Some Chinese regard this tendency to equate scientific research with routine data-collection as a relic of the Soviet influence. Following the Soviet lead, the People's Republic has adopted the policy of separating teaching (universities), research (Academia Sinica), and practice (Ministry of Geology). There is also a tendency towards premature specialisation: a student has to choose a major in one of the 10 or 15 subdepartments (such as hydrogeology or geophysical prospecting) upon entering the university.

The Soviet ideology had also a depressing effect on senior scientists who had studied in Europe or North America. Many in fact retained their positions after the liberation, but they did not seem to have received the complete trust of Chairman Mao, who repeatedly referred to the need to re-educate the bourgeois intellectuals. Some were down-graded in the aftermath of the 'Let a hundred flowers blossom' campaign of 1957; others were weeded out during the anti-rightist campaign of the late 1950s and early 1960s. Virtually none of the senior scientists survived the Great Proletarian Cultural Revolution (GPCR) of 1966-1976 unscathed, but the government was so successful in their cover-up that I learned very little of the actual happenings of the GPCR when I visited China in 1976 and 1977. The present governmental policy is not to hide the truth, however, and many of the former victims can now come out with all their woes. Physical punishment, mental torture, forced labour, and imprisonment were the lot of all intellectuals who were occupying high academic positions at the start of the GPCR; I encountered no exception among my relatives, friends, and acquaintances. Many died of suicide, or of poor health.

I consider that the persecution of the intellectuals by the Gang of Four during the GPCR was comparable to the persecution of the Jews by the Nazis during the 1930s: Red Guards or rebel cliques went about freely to search homes, to beat, insult, or imprison people. They set up kangaroo courts which could pass death sentences, without any regard to due processes of the law. There were, for example, ten such 'courts' in the University of Nanking alone! Those, such as my sister, who sat in isolation cells could see no one, talk to no one, and read nothing but the four volumes of Mao's Selected Writings. One of my former schoolmates at the University of California, who returned to serve China in 1954, was kept in a damp cellar for six and a half years, because the rebel clique believed that only a CIA spy could leave the comfort of the US to return to China: patriotism had no meaning for those cynical opportunists. (This friend is now nursing a weak heart complicated by rheumatism.)

Also persecuted during the GPCR were the middle- and high-level cadres. According to the slogans then, these cadres were the "revisionistic capitalist-roader" who enabled the "reactionary academic authorities" to betray the Revolution. Very clearly, Lin-Piao, the Gang of Four, and their followers got rid of most of their opposition. Not only were all the province chiefs changed, but all administrators down to the level of administrative assistant of a research institute or university department were at one time or another imprisoned or sent to labour camp. Productive work was suspended completely for the three years to 1969.

When operations were resumed, the men in charge were the so-called 'Worker's Representative', or 'Soldier's Representative', who had no knowledge of the work to be done. The dictatorial Soldier's Representative of the SBG, for example, declared that the practice of doing field-work during the summer and laboratory-work during the winter was a bourgeois soft-practice. Therefore, he forbade the return of field geologists to the laboratory even when the ground was snow covered. To carry out Lin-Piao's order for decentralisation, research institutes and universities were sent to the country in the provinces, where there were not enough buildings or facilities to permit normal operations. The famous Geological Institute of the University of Peking, for example, was moved to a village in Hupeh, where there was not enough space to open the packing cases, not to mention the inadequate classrooms and housing for staff and students. Consequently the institute had to remain inactive until it was sent to Wuhan after the downfall of the Gang of Four.

The lot of the young scientists was not much better. They were obliged to join one or another of the rebel cliques, which were often engaged in armed battles. At the height of GPCR, young and old professionals were forced to perform the 'Loyalty Dance' and to sing songs like schoolchildren in praise of the Great Chairman. For several years, they could not read anything other than the four volumes of the Selected Writings. They could gradually return to their work in the early 1970s, under the dictatorship of the solider's representatives who thought of geological exploration as battles to be fought, and issued orders such as: "Take that hill yonder!" The Chinese scientists were thus completely isolated from the international community for ten years.

I may have painted a horror picture of the past, and made an unflattering diagnosis of the present. However, I am optimistic of the future. The present regime has indicated the will to search for solutions to problems, and in this second campaign of "a hundred flowers", there is a liberation from fear. Free and creative thinking is now tolerated, even encouraged, rather than condemned as 'capitalistic decadence'.

During my discussions with administrators, I was encouraged by the fact that funds are available, and steps and being taken to modernise two sedimentological laboratories of the SBG. New centres with the most modern equipment will be established for paleomagnetic and for stable-isotope studies. With the concentration of financial investment and manpower of a socialist system, projects which are not practicable in capitalist countries could be carried out in China. For example, deep drilling of lakes is to take place in order to obtain continuous record of climatic changes during the Quaternary; and continuous coring of a four-thousand metre deep offshore well is scheduled to provide a Neogene reference section — something no capitalistic oil company could be persuaded to do.

My greatest consolation, however, is an awareness of the intellectual quality of the geologists and the administrators to whom I talked. After having had to fight tradition-bound arrogance for the last dozen years here in Switzerland, it is refreshing to find people willing to listen to logical agruments for innovations.

"We have a greater degree of social responsibility than UK scientists"

Joe Schwartz talks to three Chinese scientists visiting the UK about their experiences of research and politics in Britain and China.

MS KAO TSE, aged 46, a chemist from Shanghai, Mr Hsu Tan-lin, aged 38, an electrical engineer from Peking and Mr Tsang Shao-hsien, aged 40, a geophysicist also from Peking are three of a group of 12 scholars in the age group 35-50 that are now visiting the UK. Sipping green tea poured out of a large thermos flask, we discussed differences between Chinese and UK science in the plain quarters of the Chinese cultural mission in West London, far from the smart foreign embassies of South Kensington.

The training of all three has been on the European model. Ms Kao, the daughter of a university professor, attended Futan University, Shanghai's largest with 4500 students. She specialised in chemistry, the curriculum consisting of inorganic chemistry, physical chemistry and organic chemistry with mathematics up to calculus, two years of physics and a "small amount" of quantum mechanics — a standard Western course of study in 1953 the year she graduated. After teaching in Futan University for a year she attended Peking University for two years post graduate training in inorganic chemistry. She rejoined the staff at Futan University with an MSc in 1956 as an assistant instructor and was promoted to lecturer in 1959, a position she has held since.

Kao has worked on a variety of research projects but since 1973 her main work has been on the use of rare earth zeolites as catalysts and as molecular sieves. Zeolites are natually occurring alumina silicates found particularly on the ocean floor that are used as catalysts in cracking crude oil an area of international concern. Zeolites are also useful as molecular sieves in petroleum by-product refining. Kao is spending two years at Imperial College in London in the laboratory of Dr Lovat Rees, a UK specialist in zeolite research. "I came from a large research group of 25 people in Futan University. We have similar facilities but on a smaller and less well developed scale. At present China must import its larger instruments so we are behind particularly in the use of Mossbauer spectroscopy and in the use of computers.

"I didn't feel at all strange working at Imperial College and I was able to start work right from the first day. We still have a lot to learn from scientists in the UK — more advanced experimental methods and a broader knowledge of related fields. But there isn't that big a gap."

Hsu, the son of a Shanghai metal worker is working on aircraft navigation technology at Imperial College. His home institution, the Peking Aeronautical Insitute sent him to the UK "to get current with the most advanced technology in the field." His brief is digital signal processing using large integrated circuits and computer processing. Digital signals are considered to be far more reliable and easier to work with than analogue signals. Hsu thinks that China can catch up in this field within five years.

He is conversant with the debates about indigenous versus imported technological development. "The government's policy is still one of self-reliance because you can't have political independence without economic independence. We want to introduce microprocessors without becoming dependent on foreign imports. There are already many people in China working on microchip technology and we now can produce some of the chips. We are using the technology that we buy as learning equipment with the ultimate aim of producing it ourselves."

Tsang Shao-hsien's is an earthquake specilaist. His work as lecturer in geophysics at Peking University has concentrated on earthquake prediction. It is an area with extensive and unique mass participation. According to Tsang there are now 10,000 professionals and "many more" amateurs engaged in this research with every province having its seismology bureau and brigade. In this field Tsang feels that the postive aspects of the Cultural Revolution were felt more strongly than in more laboratory based work. "Earthquake prediction is in a primitive state all over the globe. In China, the professionals understood that they needed help from the people. The Cultural Revolution posed the question of theoretical work versus parctical work and before 1975 'mass work' instead of professional work was emphasised. In 1973 our efforts were to build more instruments and organise more people. China has good social organisation and earthquake research lends itself to this since the science and the socio-political work can be organised together."

Workers at the Shanghai Machine Tools Plant: a model for training technicians

Tsang thinks, however, that theoretical work has been neglected. He has been in the UK for two years familiarising himself with UK theoretical work in the field.

On the wider questions of science policy, education and economic development Kao, Hsu, and Tsang were forthright but at the same time circumspect in the expression of their views. All three believe in quality education. Kao was particularly impressed by recent UK Conservative policy in this area. "I think the Thatcher policy of emphasising aid to the independent schools is important. Some schools should be better than others. In China we have a policy of selecting 'key schools' to make an example for the others."

None of the three saw any danger in the possible domination of education by a small group of intellectuals and party officials. Present policy is that graduates from middle school at age 16 can apply for three years further schooling through competitive examinations set by each city. This is to be compared to policies adopted during the Cultural Revolution when university places went to students elected from their place of work. The example of the Shanghai Machine Tools Factory was important enough for Mao to refer to it in a policy statement on science education in 1968: "It is still necessary to have universities; I refer here mainly to colleges of sciences and engineering. However it is essential to shorten the length of schooling and to make it more political as the Shanghai Machine Tools Plant has done in training technicians from among the workers. Students should be selected from workers and peasants with practical experience and they should return to production after a few years study".

Kao, Hsu and Tsang were familiar with this policy but dismissed it as being "unrealistic." "We would like to enroll all middle school graduates but we must select" says Tsang. Hsu feels that the arguments put forward during the Cultural Revolution were "worthless" and that scientists must "concentrate their efforts on doing scientific work" instead of "being occupied with politics."

When asked whether they saw any differences in the way the UK organised its scientific work compared to China, Kao answered for the group. "In China we tend to work more collectively. It is unheard of for an individual to work alone whereas this is quite common in the UK scientists. Here in the UK, scientists do their work because it interests them. But in China we have adopted the saying "serve the people" as our guiding policy. We believe that the work should be useful first and interesting second. Otherwise it is not good for the human being." □

One culture bridging two

Samuel Ting, discoverer of the J particle, is a Chinese scientist living and working in the West. Here he talks to **Christine King**

SAMUEL Ting is an American citizen by "an accident of birth". His parents, both professors, were on a visit to Ann Arbor, Michigan, from China in 1936 when he was born. Ting says "my parents had hoped that I would be born in China, but I was born prematurely. Two months after my birth we returned to China." During those early years, China was a country torn by war, so formal education was impossible until he was twelve. Ting remembers now that this lack of continuity in education was compensated by meeting the many scholars who frequently visited their home. Ting's present reputation for hard work and being a highly demanding task-master has its origins perhaps in these early years.

"Since both my parents were working, I was brought up by my maternal grandmother, who was a very courageous and determined person. My grandfather had lost his life in the first Chinese Revolution. After that my grandmother returned to school, became a teacher and brought up my mother alone. When I was very young, I often heard stories from them recalling the difficult lives they had, and the great efforts they made to provide my mother with a good education. Both of them left an indelible impression on me."

Ting attended schools in China and later Taiwan, and decided to return to the US to continue his education at the University of Michigan. "At the time, I knew very little English and had no idea of the cost of living in the US. In China, I had read that many American students go through college on their own resources. I informed my parents that I would do likewise. I arrived at Detroit Airport on 6 September 1956 with $100, which at the time seemed more than adequate. I was somewhat frightened, did not know anyone and communication was difficult". These were hard years for Samuel Ting, competing constantly for scholarships.

In 1963, with a doctorate and as a Ford Fellow, he went to CERN (the European organisation for nuclear research in Geneva) and came under the guidance of Guiseppe Cocconi, working with the Proton Synchrotron.

After this initiation into European high energy physics, Ting returned to lecture at Columbia University. Here he worked with leading physicists including Steinberger, Schwartz, C.S. Wu, and T.D. Lee. It was during these years at Columbia that his — then unfashionable — interest in electron-positron pair production began.

At the Cambridge Electron Accelerator an experiment on e^+e^- pair production in photon collisions with nuclear targets appeared to show a violation of quantum electrodynamics. (QED is the relativistic quantum theory of electromagnetism; it remains the most accurately tested of all physical theories.) Ting studied the apparent violation with increasing interest and eventually asked Willi Jentschke of the DESY (Deutches Electronen Synchrotron) laboratory in Hamburg about doing a pair production experiment at Hamburg. By this time Ting was fully committed to investigating the decay of photon-like particles, and searching for new particles which decayed to electron or muon pairs. In 1971 he returned with his group to the US and began experiments at the Brookhaven National Laboratory. It was here, in late 1974, that Ting and his group found evidence of a new, totally unpredicted and long-lived heavy particle, the J or psi-particle, which was subsequently shown to contain charmed quarks. For this work, Ting shared the Nobel Prize for physics in 1976 with Burton Richter.

With Ting's growing reputation as a leading physicist have come new problems. In the present political climate of growing intercourse between the US and China, Ting's participation is inevitable. His group at DESY was amongst the first to receive physicists from the Institute of High Energy Physics in Peking to work in the West. The Chinese Press consistently refer to visiting scientists like Ting, and fellow Nobelists Yang and Lee, as Chinese-American or just American. Ting however, is a totally apolitical figure. He categorically repeats "I am not interested in politics and never have been; I have never voted (in the US).

On his trip to China a few weeks ago, Ting was feted by the Chinese Academy of Sciences (CAS), and as on previous visits, talked privately with Chinese leaders Chairman Hua and Vice-premier Fang Yi, who is also president of the CAS. They talked of China's modernisation programme but, Ting says, they have never discussed political issues "probably because they already know my views".

Ting believes that since he goes to China to communicate with Chinese physicists, there is no time to sightsee. Each of his visits has been widely reported in the Chinese press, and every time his lectures have been attended by thousands. At first he had difficulty lecturing in Chinese (he has spent more of his life on the West than in China): "my audience of several thousand was hardly able to contain their mirth, and corrected me several times on scientific terminology. But I persisted and now it's no longer a problem."

To the outside world, China's decision to pursue high energy physics as part of its modernisation programme, is, to say the least, puzzling. "As I see it" said Ting, "although particle physics appears very complex, its fundamental principles are nevertheless extremely simple . . . Major discoveries are made by only a few individuals and China has plenty of these. It is an expensive pursuit, but it's also the most fundamental — and it's cheap by comparison to what's spent on defence, say." He believes that the Chinese will maintain their independence in high energy physics. But China's future scientific progress is not a subject which he, or anyone else outside China would feel qualified to predict.

Samuel Ting: not interested in politics

Ting belongs to a new generation of jet-setting academics, spending much of his time at DESY, where he is pursuing the search for the intermediate vector boson at PETRA, currently the world's most sophisticated electron-positron colliding beam device. To keep abreast of his commitments at MIT where he is professor of physics, he flies between Boston and Hamburg on average once a fortnight.

Despite his reputation for working his team hard, no-one works harder than Ting himself. How does life in Hamburg differ from his life in the US? "My life in Hamburg is work, work and more work. As for my team, I try to choose only those who also like to work hard." Interviewing Ting can be a formidable experience if one expects any human foibles — in his own words, he does not smoke, drink or gamble, nor does he read fiction. His family now lives in the US, although the children spent many years in Germany. When he arrives home, do his children complain that they don't see enough of him? "Yes, all the time." Like many Chinese fathers, Ting is determined that his children should put their studies first. When I remarked that in talking of his children, he had repeatedly said only how he expected them to work hard and do well at school, Ting gave a rare laugh. "It's true — around the block where I live, I'm known as the 'bad guy', because I'm so strict with them."

When Ting is not pursing theoretical particle physics, his predilection is very much towards history. He regards Faraday as a notable historical figure, admiring not only his great breadth of vision but also the difficult and determined path by which he achieved his mastery of science. To be seen as another Faraday — no doubt that would be Samuel Ting's dream. □

The solar wind connection

from Alan Johnstone

THE solar wind is deflected around the Earth by the Earth's magnetic field. The electrical currents which flow in the boundary layer between the solar wind and the magnetosphere shield the solar wind from the Earth's magnetic field. In 1961, Dungey suggested, that, if the magnetic field, of solar origin, in the solar wind was opposite in direction to the Earth's field at the boundary (called the magnetopause) then the two magnetic fields would diffuse into each other and some geomagnetic field lines would become connected to solar wind field lines (Fig. 1). The geomagnetic ends of the field would be dragged behind the Earth by the solar wind to form a long magnetospheric tail. In the tail the geomagnetic field lines would become reconnected again, and return to the interior of the magnetosphere. The plasma flow driven by this process transfers energy from the solar wind to the magnetosphere, and if sufficient magnetic connection occurred it could produce magnetic storms and auroras.

It is now known that some geomagnetic field lines connect to the solar wind, that the pattern of plasma flow is similar to that driven by such a process and that geomagnetic activity is greater when the solar wind is more nearly opposite the Earth's field (that is, southward directed). Until recently there has been no evidence on the microscopic scale from spacecraft that connection takes place at the magnetopause.

The fields and plasma flow near a region of magnetic connection are shown in Fig. 2. The shielding electric current J flows out of the paper. In a closed magnetosphere the magnetic field on both sides is parallel to the surface. The signature of magnetic connection is a small component B_n normal to the boundary. Although spacecraft magnetometers are very accurate the local surface plane of the magnetopause cannot be determined from a single spacecraft, or even a pair like ISEE (International Sun Earth Explorer) 1 and 2, so that a small normal component cannot be reliably identified.

Another indication of magnetic connection is an electric field E tangential to the magnetopause. The electric field is more difficult to measure than the magnetic field in tenuous plasma and the first measurements at the magnetopause were not made until 1977 by ISEE 1, and 2, more than 13 years after the first observations of the magnetic field. Mozer *et al.* (*Geophys. Res. Lett.* **6**, 305; 1979) have reported the existence of a tangential electric field of the order of 2 mV m^{-1} during a series of crossings of the magnetopause in the subsolar region. There were large fluctuations, taking the value to zero on some occasions.

Heikkila (*J. Geophys. Res.* **83**, 1071; 1978; unpublished work, 1979) has argued that a crucial test for magnetic connection is to find what happened to the electromagnetic energy dissipated in the magnetopause, where $E.J$ is positive (in the particular planar geometry of Fig. 2, E is parallel to J). In the case reported by Mozer *et al.* (*op. cit.*) the power dissipated locally is estimated to be 70±20 W km^{-2}. This energy must go into the particle distribution. According to theory, plasma flows from both sides towards the boundary where it is accelerated parallel to the surface by the electric motor force $J \times B_n$. In more picturesque terms, it is catapulted out of the region by the tension in the magnetic field lines. Heikkila (*op. cit.*) showed that the energy deposited in the particle distribution should be observable whether or not this simple picture is correct. Yet, despite many magnetopause crossings by several spacecraft carrying suitable instruments, no part of the particle distribution had been found to be carrying the excess energy until a crossing described in this issue of *Nature* by Paschmann *et al.* (page 243). They have found a crossing where a high speed flow in the magnetopause is observed by both ISEE spacecraft. The flow velocity of plasma in the layer was 450 km s^{-1}; much higher than flow velocities in the adjacent magnetosheath and consistent with the simple picture of acceleration by a magnetic catapult. They estimate a power dissipation of 78±24 W km^{-2}, almost the same as Mozer *et al.* found from electric and magnetic field measurements. Unfortunately, during this crossing, the electric field instrument,

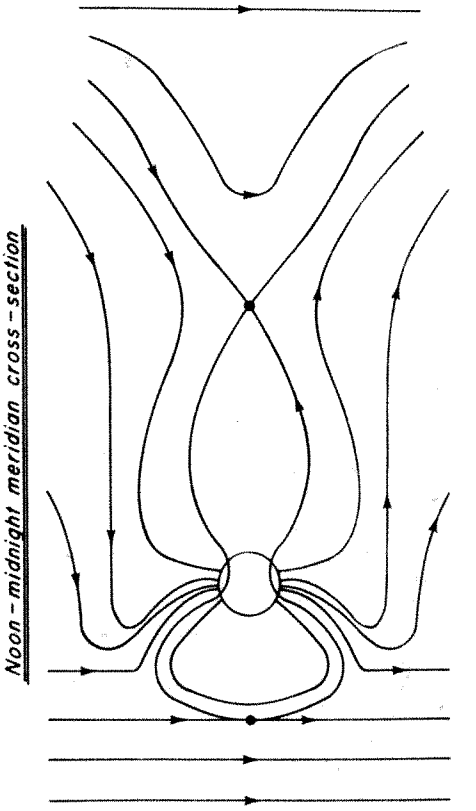

Fig. 1 The magnetic configuration of an open magnetosphere in a southward-pointing, interplanetary magnetic field as proposed by Dungey.

Alan Johnstone is at the Mullard Space Science Laboratory of University College London.

0028-0836/79/460229-02$01.00

©1979 Macmillan Journals Ltd

which was on the same spacecraft, was in an unfavourable mode. During the crossing reported by Mozer *et al.* the same particle detectors show no sign of the acceleration (Heikkila *op. cit.*).

Although the latest result of Paschmann *et al.* provides strong support for magnetic connection it also reinforces the criticisms of Heikkila (*op. cit.*). If the effect is so easily detected in this crossing why has it never been reported before? If magnetic connection occurs it can hardly be such a rare event as the present observational statistics imply. Is it confined to a small region of the magnetopause or are there special conditions yet to be identified? Other examples, which Paschmann *et al.* say have already been found in the ISEE data, may provide the answers and help us find out what controls the rate of energy input from the solar wind into the magnetosphere. □

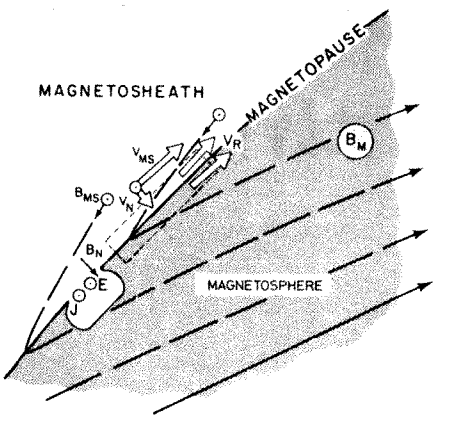

Fig. 2 The configuration of magnetic (B) and electric (E) fields and plasma flow (V) (broad arrows) when magnetic connection occurs at the magnetopause. The enhanced flow caused by acceleration in the layer, V_R, exceeds the normal flow of solar wind plasma past the magnetosphere V_{MS}.

Immunoglobulins and histocompatibility antigens

from Arnold Feinstein

THE family of antibody molecules, or immunoglobulins, for all its magnificent variety and versatility of structure, function and specificity, has evolved by the multiplication of a gene coding for a single ancestral polypeptide sequence, corresponding to a size of about 12,000 molecular weight. As a result of tandem duplication, followed by limited divergence, four or five homologous sequences can be seen repeated along the heavy polypeptide chains of antibody molecules. The κ or λ light chain found in association with each heavy chain is formed from two such homologous regions. In both heavy and light chains hypervariable stretches conferring antigen-binding specificity are confined to the most N-terminal homology region, the so-called variable region. Crystallographic studies of a few immunoglobulins have revealed that variable and constant homology regions are independently folded similarly, but distinguishably, into individual domains.

What makes it quite certain that the chains of all known antibodies are strings of such similarly folded domains is that all the characteristic conserved features of the folded domain, seen by crystallographers, are easily detected in each of the homologous sequences recurring along all the known immunoglobulin polypeptide chains (see Beale & Feinstein *Q. Rev. Biophys.* **9**. 135; 1976). These features include the β strands which form two β sheets, the bends between the strands, and the disulphide bridge lying between the two sheets and linking them. In this way we have the rare good fortune to be able to come close to the tertiary structure of an immunoglobulin domain from a knowledge of only its primary sequence. Now that the sequences of more proteins are becoming available, the basic immunoglobulin domain structure seems to be cropping up in several unrelated membrane proteins.

It has been evident for some time that another remarkable family of molecules, the classical transplantation antigens (the histocompatibility antigens), are in part coded for by genes which have evolved from the same ancestral immunoglobulin gene although the two loci are completely unlinked. These highly polymorphic antigens are present on most cells, and are extremely important, not only as the critical targets in graft rejection, but also for their involvement in the recognition by cytotoxic T lymphocytes of viral and other cell surface antigens (see *News & Views* **274**, 12, 840; 1978). The histocompatibility antigens consist of two non-covalently associated polypeptide chains, the heavier one, which carries the alloantigenic specificities, being a 44,000 molecular weight glycopeptide; the other subunit, β2 microglobulin, has a molecular weight of 12,000, and its invariant amino acid sequence was found, surprisingly, to be homologous to that of a constant immunoglobulin domain, including the characteristic disulphide-bridged loop. Moreover, all the three-dimensional structural features of this domain referred to earlier can be recognised.

In antibody molecules constant domains regularly associate in pairs, so that when two disulphide-bridged loops of appropriate size were seen in the heavy chain of the transplantation antigen, it seemed very likely that at least one of these looped regions would be folded like an immunoglobulin domain, and would be associated with β2 microglobulin. Indeed, the familiar features of a constant immunoglobulin domain could already be seen in a tentative sequence of one of these regions, in a human histocompatibility antigen, which was published last year by Strominger and his colleagues.

In this issue of *Nature* (page 266) Orr *et al.* present the complete sequence of this region, referred to as ac2, and confirm in detail its immunoglobulin-like structure. But what of the other more N-terminal disulphide-looped region? (see Fig. 1 of Orr *et al.* for the relative arrangement of the regions). The sequence of this region too has now been published (*Proc. natn. Acad. Sci. U.S.A.* **76**, 4395; 1979) and it is disappointingly apparent that, apart from the sequence around the most N-terminal cysteine, the overall pattern of conserved features typical of an immunoglobulin domain are not clearly seen. Thus, even if this region were derived originally from an ancestral immunoglobulin gene, it has adaptively lost a number of its features. For this reason, ac2 is a more likely candidate for the region with which β2 microglobulin is associated.

There is however, certain to be a concerted effort to predict a plausible structure for the region N-terminal to ac2, following the realisation that this part of the molecule is important in T cell recognition. This awareness has been highlighted by studies of mutant mice, where dramatic functional changes have been correlated with single amino-acid substitutions in this region (see Kohn *et al. Immunogenetics* **7**, 279; 1978). Not only can such mutations lead to graft rejection, but the specificity for T cell recognition of viral antigens seen in association with the original and with the mutant molecule can be quite different.

It appears that each of the different types of polypeptide chain known to contain immunoglobulin or related sequences is controlled by one of five genetic regions, which are not detectably linked in the species studied. It seems that we can now add a sixth. Thy-1 is a glycoprotein which has been isolated by an Oxford group from rat brain, but it is also abundant on rodent thymus cells. Its sequence indicates that Thy-1 resembles a single immunoglobulin domain (see Campbell *et al.* this issue of *Nature*, page 341). Although the function of this molecule is unknown, we should in general resist the expectation that invariant proteins structurally related to immunoglobulins will have specific recognition properties analogous to those of the specialised variable domains of antibodies. We do not know what function the ancestral polypeptide served, but we have every indication that it owes its extensive proliferation, unique in mammals, to its striking adaptability to a variety of functions.
